# THE GREAT COURSE OF MEDICAL ENDEAVOR

## PRESIDENT'S ADDRESS

E. H. CARY, M.D.
DALLAS, TEXAS

Suppose we stand on the high bridge that crosses the stream of knowledge, to gain a perspective of the entrance of medicine into the affairs of man. Far up the tortuous course we look, and strive to interpret the events which have influenced the flow of the thoughts of man—which have set him free. We see an infinite variety of streams, some sluggish, some strong, all entering the channel, with here and there a beacon light to illumine the way. Men of letters, scientists, artists and philosophers have had the opportunity of contributing to this stream. For this ability they have needed one requisite—an open mind; for fixed opinions retard the waters of clear-flowing truth.

We recognize with humility that, although truth is eternal, there can be reasonable doubt even as to accepted certainties. An open mind is the bulwark of wisdom. Some one has spoken of the deep slumber of a decided opinion.

Ever so often there is added something to the river of knowledge which broadens the stream.

We behold the men of medicine, who have contributed so largely to this ever flowing and deepening river. Some of these men we classify as fathers of our art, for they contributed to that thinking which in easy stages led to the fuller development of the underlying physical sciences. The oldest treatise that can be classified as a beginning of imparted science, written in Egypt some five thousand years ago, concerned itself with surgery.

Nature, as harsh as she has seemed to man, has always offered the same problems for solution, but man's early interpretations were in a large measure defensive; hence they required adjustment. The chronology of man's escape from the bondage of his ignorance of natural laws is almost as simple as the story of certain individuals whose interpretations of certain facts became the mainspring in changing the thinking and activity of those who could carry on.

### CONTRIBUTORS TO KNOWLEDGE

To trace the details of the sequential development of the different sciences is not my purpose. The number of men who have influenced the field of workers has been limited. Geniuses have at all times been terribly misunderstood, handicapped and abused; yet, as God will have it, men arise to interpret the past and to project possibilities for the future.

Apparently there is always a contributor toward the sequence of things. The high points are reached by the interpreters of nature, as disclosed to them by their stimulated senses. But we must not forget that the men who left us our heritage were patient observers; they were willing to repeat their observations, to recheck their conclusions, and to correlate those conclusions with the results of previous researches.

Shortly before his death, Isaac Newton wrote: "I know not what the world will think of my labor, but to myself it seems that I have been but as a child playing on the seashore; ever finding some prettier pebble, or more beautiful shell than my companions, while the unbounded Ocean of Truth lay undiscovered before me." He did not close the door to investigating minds to come. He did see far beyond his own environment and influenced the life of man for all time. Einstein may have changed a fixed conception; but one that was evidently so in harmony with correlated knowledge remains still useful and as yet unbroken.

We have here an illustration of the importance of landmarks. They serve a great purpose, but they should never check the flow of the mind. If a so-called immutable law, such as Newton's, is at variance with the truth, how can any man be intolerant or dogmatic? Schiller suggests that "Truth never is,—always is a-being."

While hurriedly traversing in the most cursory manner both time and its content, to reach a point when medicine became an important branch of the stream of knowledge, we are reminded that the fanaticism of the zealot has been eternally at war with progress; and even in the Reformation, which is the basis of our liberty and of our scientific development, there was great weakness in interpreting the physical status of man. John Stuart Mill says on liberty: "Truth, in the great practical concerns of life, is so much a question of reconciling and combining of opposites that very few have minds sufficiently capacious and impartial to make the adjustment with an approach to correctness; and it has to be made by the rough process of the struggle between combatants, fighting under hostile banners."

As wonderful as the world was to the brilliant Greeks, who had observed the best thought of preceding civilization, their information of scientific value necessarily was exceedingly limited. Yet it is interesting to note that they have been credited with suggesting nearly all of our present-day accepted facts, even that of relativity. It is not my purpose to describe or to delve into the well known causes of their failure. Disraeli, speaking of the successors to the Greeks, said: "The Romans were practical men who practiced the errors of their forefathers."

---

President's address before the American Medical Association at the Eighty-Third Annual Session, New Orleans, May 10, 1932.

### PROGRESS IN SCIENTIFIC IDEAS

Yet it is certain that both science and the true method of science existed in antiquity, without the basic thought being properly developed. It was not so much the errors of the ancient world as the errors of the Middle Ages in interpreting the lore of the ancient world that retarded development. The undue importance assigned to Aristotle held back science during the first century of the Renaissance. William Harvey's book presents an illuminating contrast between the false learning of the Middle Ages and the positive knowledge of modern times. As we approach the twentieth century, when the minute things of this world were revealed and their purposes discovered, the study of physiology was opening new vistas. The wonders of the mechanism of life therein contained only accentuated the ever increasing regard which man must have for his Creator. It is not difficult to understand why mental and spiritual readjustments are all on a higher plane. Our present conception of that Power which governs all is not by any means the same view which the mass of men held not so long ago.

There apparently exists today greater capacity in more places than ever before. Truth in all its ramifications is more willingly viewed from every angle. Our modern facilities for spreading correlated information makes it so.

In our day there has been both liberty and science. There has been opportunity for gaining information of all kinds, and the children of the present have frequently become the teachers of the parent. The kindness of the state has made it easy for parents to conclude that all knowledge, both moral and physical, should become the work of the state, and it is only natural for them to shirk their responsibility. Gradually the social fabric is changed.

This condition is but one of the fruits of our educational system, and similarly the opportunity arises through that system to discourage individualism. If this is true, the effect may tend to paternalism. We who are concerned in preserving the individualism of medical practice in the interest of the people must recognize the danger from any mechanism, whether educational or otherwise, that tends to create a paternalistic interference by the state. While we cannot dam the stream we may divert it, to protect the art of medicine from flood waters.

Science is yet young, and in the days to come there are bound to be radical alterations in our present conceptions, particularly those which concern mind and its place in the scientific scheme.

Change in scientific ideas is counted a distinct progress, while change in religious ideas is looked on in a different way. Change is conceded in the one, fixed opinion in the other. This should not be true. We should never mistake wish for fact. A strong desire is no proof that the object of that desire exists. Widespread application of a correct approach to knowledge, and the study of cause and effect in the underlying branches, have hastened the day of scientific medicine.

The great technological age has brought its joys and sorrows. It has led man to the mountain tops; he has ridden from one oasis to another and sailed from port to port. Our era has exaggerated production and has had to stop for adjustment, thereby distressing the world. Medical men share the world's despair, but as men of science we cannot believe in the inevitability of these unfortunate cycles. Meanwhile, in the present crisis, the training and mental equipment of the diagnostician should make the wise medical man helpful in finding causes of distress and enable him to offer valuable suggestions for relief.

It has been said by Wilde that "Life and the world are not struggling against an alien force, but struggling to overcome simply the past."

When a boy, while in a small church, I saw over the baptistry a great circle with letters in gold saying "God is Love," which emotion in the spiritual world is said to be similar to the action of gravitational force in the physical world. This interpretation was emphasized beautifully by the lowly Nazarene. But God, too, is truth, a creator and scientific maker of law, the manifestation of which, in minutia and in magnitude, is our greatest evidence of this fact. Science, art, religion and philosophy, as well as the human mind, have, we believe, evolved from somewhere and are forever on the way.

Science is striving to interpret and discover, bit by bit, this magnitude of mind, and man is nobler and nearer the Creator by each interpretation thereof—his horizon broadened and his soul awed by the immensity and beauty of this vision.

Truth, that ever elusive force, is difficult to circumscribe—a different point of view, a different mental slant, may destroy that which we believe; yet a broader, deeper interpretation of accepted truths is developed as we willingly submit all suppositions to a searching analysis.

Onward goes the march of the science and art of medicine, eliminating the enemies of man, one or more at a time, binding the wounds and tending the weak, working for a more perfect condition.

Huxley said: "Science inculcates veracity of thought and action, without which there can be no alleviation to the suffering of mankind."

Pasteur said: "The cultivation of science in its highest expression is perhaps more necessary to the moral condition than to the material prosperity of a nation."

### THE SCIENTIFIC CULTIVATION OF MEDICINE

Contributing perhaps more than any other factor to the furtherance of this scientific cultivation of medicine is the great channel the American Medical Association affords the different branches of medical knowledge, which collaborate therein, obtaining thereby the best opportunity for the highest development of our art.

This great organization, imbued with this larger conception, centered its attention on education and on what could be accomplished through concerted educational zeal, as one of its chief claims for cooperative effort. So it came to pass that the great motif, from 1847 until now, has been the advancement of the science of medicine through educational achievements, so that both the theory and practice of medicine could be harmonized, through an ever growing art and science, for the good of humanity.

When we speak of the achievements of the American Medical Association, we start with the educational program outlined by our forefathers, recognizing their wisdom and foresight and the fruits of their planting as they were ripened in the most orderly fashion by the astute leaders who have directed and guided the affairs of this great power and body.

Strangely true, most of this monumental work can be seen by these men who have survived and are here to see and enjoy the accomplishments of their planning. One of these men approaches the honorable age of the octogenarian, another has already achieved this remarkable goal—both are still contributing their unstinted interest and inspiration to the American Medical Association. While personal allusion is unnecessary, any student of our history will recognize these outstanding characters.

No child of this parent body should ever grow so lusty, ambitious or proud as to disturb the confidence in, or function of, this great organization in building reliance in the policies of the profession as a whole. Voluminous data have been furnished me by the heads of the different departments which comprise the American Medical Association, making complete its service. I regret that time prevents me from presenting more of this information. No one man could comprehend the vast endeavors carried on by our organization without devoting time to a daily survey of the work being accomplished. I commend this ever increasing program of service to your attention, hoping that more of our members will visit headquarters and become acquainted with its high purposes and extensive and effective routine. It bridges the chasm between professional accomplishments and public needs.

### ACTIVITIES OF THE AMERICAN MEDICAL ASSOCIATION

When the body of American physicians developed our organizations into a representative government, it was made possible for the ideals of the noblest of all professions to evolve in a most orderly manner. It became the duty of The Journal to mold the minds and develop the aspirations of the medical profession—to guide its hopes and clarify its problems; to give support to all things which elevate the profession.

That this has been accomplished is acknowledged by all who know. Today the greatest medical journal printed in the world is ours. It has its satellites, which illumine all branches of the art and science of medicine, assuring a perpetuation of the hopes and aspirations of those pioneers in our profession who led the way for the organization in special journals, until we were ready to take over their task and make permanent the labor so freely given in the years gone by.

What a vast and beneficent work this organization does for its members! One of the most clarifying yet prosaic printed abstractions, which is so necessary for our common information, is the dignified Medical Directory. It brings to us an intimate knowledge of 156,000 doctors, all based on the most extensive biographic material, which increases with the individuals' activities.

Few of our members realize the world-wide significance of our taking over the important task of publishing the laboriously gathered data into the *Quarterly Cumulative Index Medicus,* which serves the scientifically minded world and is a tremendous aid to research. It records the efforts of medical men appearing in 1,400 journals.

This improved service has made every library more efficient. Medical literature has become more intimate to those interested. This great work is a real contribution of no mean proportion. It is undertaken at an expense far beyond the monetary return and is an outstanding philanthropic activity of the American Medical Association.

At this point, I might call your attention to the ever increasing importance of our effort, through the publication of *Hygeia,* to invade the homes and reach the people of this country in a language easily understood, regarding the health and welfare of the people themselves. If the people were educated in the basic sciences, they would not so readily yield to propaganda harmful to themselves. The truth is easily perverted and pseudoscience is attractive. *Hygeia* fills a need in carrying health messages. While its distribution has reached 60,000 copies a month and it is no longer a financial burden to the organization, its true worth to the public will be better exemplified when ten times this number of copies is printed and read each month.

### WORK OF THE COUNCILS

The Council on Medical Education and Hospitals has by study, example and inspection played the leading rôle in developing the present strong group of well established and efficiently operated medical schools. Through its interest in the educational possibilities of the hospital, and its classification of hospitals for interns, it has contributed in a striking manner to the nation-wide improvement of public and private hospitals. Clinical laboratories have also been elevated to a generally acceptable basis. Roentgenologists in our profession have suggested and aided in grading the standards for the x-ray laboratories of the country.

The Council has wisely coordinated all other forces in these fields and has been able to accomplish results through cooperation. Public information about the many conferences has been printed, particularly the regular conferences held each year in which various other bodies, including the Association of American Medical Colleges, the National Federation of State Licensing Boards and the American Hospital Association, have taken part. In this open forum the leaders have been heard, and policies regarding medical education and medical practices have been determined.

The Council is now making a study of mental hospitals and anticipates that it can bring about improvement in this vital and important field.

The leadership exerted by the Council on Medical Education and Hospitals has been of world-wide interest, particularly to those seeking development of higher standards of medical education, correct hospital procedure and a more satisfactory practice of medicine.

Another important council is the Council on Pharmacy and Chemistry. Let me take your thoughts backward to that period from 1900 to 1906 when a most constructive work was initiated, the magnitude of which rises with the increased perspective of the last twenty-five years.

In America, the development of so-called ethical preparations began about 1875 and grew to serious proportions in the first part of this century. The profession was aware that it had no means of determining in which new drugs it could have confidence, claims for which were preposterous even then. The informed public, aided by organized medicine and other agencies, such as *Collier's Magazine* and the following of Dr. Harvey W. Wiley, demanded protection against impure foods as well as drugs. This was a period of crusading for the public's own protection in these health sustaining commodities.

The medical organization and the legislatures became alive to the situation. The passage of the Food and Drugs Act in 1906 was an outgrowth of this agitation. The necessity for this reform is attested by the fact that even in the issues of our own Journal in 1900 may be found the advertisements of seventy-two proprietary preparations. Of these only about 12.5 per cent were subsequently admitted to New and Nonofficial Remedies, and of these nine not a single one is now included in the book, thus showing how therapeutics has progressed since that time.

The Council has carried on its work for twenty-seven years. It created a set of rules which in essence stands today as a guide to the Council. Thirty years ago the advertising pages of medical journals were not dignified nor creditable. This has all been corrected through the Council's efforts in furthering rational therapy.

In strong contrast, many European journals carry the advertisements of products which are not permitted in our journals. Under the influence of the Council, the profession has become more critical in regard to drugs—and more scientifically minded.

Drug manufacture has been materially benefited by the work of the laboratory. It has caused the directors of pharmaceutic houses to recognize the importance of scientific research and control, so that today most of the pharmaceutic houses have competent research staffs and are adding their contributions to the advancement of materia medica.

This contribution to public service is maintained by the Association as a safeguard to the public.

It is possible that some day the Chemical Laboratory may be enlarged, so that many activities can be broadened; market specimens of accepted drugs should be examined frequently, giving greater assurance of the quality and continued compliance with standards. We should also develop a bacteriologic laboratory which will control and report on the sutures which are used every day by physicians, and which will examine vaccines and serums for purity and potency.

The work of the Council on Pharmacy and Chemistry and the work of the Laboratory has been an altruistic effort in practical education.

The Council on Pharmacy and Chemistry has made the medical profession articulate against the unscrupulous who manufacture and distribute proprietary medical preparations. Without its work, without the cooperation of the fine minds directing the manufacture of medicaments, we would not have the distinction of having accomplished this great program of practical education, which is a program valuable to the public and inspiring to the profession.

Here I would call attention to the fact that each of the councils created by you has a separate fund for making grants for special research. These have been wisely administered. If you will read the report of the Board of Trustees, you will see how far reaching, how helpful and stimulating are these grants of money to the furtherance of medical accomplishments, through which many young minds find material assistance at the most opportune time.

### LEGISLATIVE ACTIVITIES

While it is true that medical men in a general way have avoided the legislative halls of this country, it is also true that those who legislate for us cannot deal with matters relating to the public health intelligently without taking council of informed medical opinion. It is conceivable that confusion might be even worse confounded if there were not an organization such as ours to develop policies and indicate our views for the common good of the doctor and the protection of the public.

A legislative committee was created by the last House of Delegates. The cooperation of this committee with members of the American Legion and with the American Hospital Association has already demonstrated the wisdom of exchanging different points of view. Out of the many conferences has grown a permanent committee representing the three organizations, which it is hoped will more sagely guide legislation in the interest of the public as well as the physician. Allow me to suggest that you become thoroughly familiar with this committee's activities. Your active support would be of great value.

The legislative committees of the states should stand ready to cooperate with the central committee created by the House of Delegates, whenever they are called on, making concentrated effort on national legislation when desired.

### EDUCATION OF THE PUBLIC

Regarding the education of the public, we conceive it to be our duty to disseminate as much of our knowledge as the people will absorb. We realize human attitudes and aptitudes, and we know that the art of medicine is best expressed in the wise use of the science of medicine.

As to the control of quackery, we have all observed that it is not the quantity of learning that individuals have but the quality they possess which makes it possible for them to differentiate between what is true or false. The most widely read and most expressive editor in the secular press may enlarge on his interpretation of progress, formulating a doctrine dangerous to the health of the community, because he lacks knowledge of the fundamental sciences. It is also true that the exaggerated statements of our co-workers, claiming specific knowledge or new discoveries which have not been proven, are quite as embarrassing. We have a right as physicians to enter a protest against unripe conclusions, hurriedly projected as scientific facts, from either source.

A too ready credence of such statements by both the profession and the public is a compliment to the high place science has reached in the minds of the people. Our chief danger from quackery at this time seems to be from the pseudoscientists and the overambitious, who make exaggerated claims and yet remain in the eyes of the public a part of the scientific world.

The radio, which is capable of bringing happiness and information, is being diverted and prostituted by designing and resourceful charlatans, who enrich themselves at the expense of decency, truth and humanity. The Radio Commission should protect the people who are not able to differentiate for themselves.

We must commend the enlightened secular press, which has made it difficult for quackery to exist. The radio must not be the door to the people which that enlightened press had succeeded in closing.

### MEDICAL ECONOMICS

I come now to the Bureau of Medical Economics, which was established to study all the phases of general economics which have a bearing on the practice of medicine. In every consideration of this subject it must be remembered that a profession has for its prime object the service it can render to humanity. Reward for financial gain should be a subordinate consideration. The practice of medicine must remain a profession.

Although business methods and economic principles are essential to an orderly conduct of the financial phase of the practice of medicine, they must serve, rather than dominate, the profession; they must be secondary to the primary object of service, and they must conform to the accepted principles of medical ethics. The principles of medical economics should not be perverted to defend the borderline activities of the charlatan. There is a vast detail of activity going on in our organization to meet the necessities of the situation. This technological age has brought new conditions and strange fellowships, altogether diverting, and sometimes perverting. I hold that it is within our province to solve all the problems concerned in the practice of medicine. The people await our decision.

If we are to preserve individualism and the fine relation that has ever existed between physician and patient, we must with renewed zeal and exceptional energy seek an answer to the problems which are related to the economic side of the practice of medicine. I shall bring to the attention of the House of Delegates certain matters related to this subject.

### FURTHER ACCOMPLISHMENTS

I should now like to direct attention to one of the most important committees connected with the organization—the Council on Scientific Assembly. The gradual improvement of the section programs has been made possible by the larger number of applications for places and the care with which the papers have been selected. The Scientific Exhibit has steadily improved. From now on a greater effort will be made to coordinate the scientific exhibit with the section program. Increasingly popular are those exhibits in which a competent demonstrator remains during the session.

With the proper speakers, the clinical lectures will fulfil a useful function by giving a large number of physicians a chance to hear the practical results of new methods of diagnosis and treatment which have been sufficiently well proved to be of value in everyday work. In a similar manner the public addresses, the valuable scientific contributions being read within the sections, together with the scientific and technical exhibits, produce a tremendous mass attack for enlightenment—an attack which undoubtedly advances the science of medicine, both locally and throughout the nation.

Medicine is popularized; it is brought home to the people; and I am glad to say that our distinguished editor fully appreciates his opportunity. He has cooperated faithfully with the press and has proved to it the value of exact information.. This contact is increasingly important, for the responsible press is sincerely interested in the truth.

### REMAINING TASKS

So I might go on and on with the accomplishments and possibilities of organized medicine as it is now progressing. We know that there are problems in the process of solution, and that there are others highly important, made more complex through social maladjustments. It is our bounden duty to bring to bear on these problems the best thought of the members of our own profession, men who are guided by education and wisdom based on experience.

We realize that the public weal is the chief concern of our profession, and that there are two methods of approach in the application of medical knowledge to the welfare of the people.

We encourage the graduation of Doctors of Public Health. We continue to educate the majority of medical men for individualistic practice.

There should be no conflict between those who are primarily interested in preventive medicine and those whose lives are devoted more definitely to curative medicine.

The public health officers who best understand the needs of the people jealously direct their departments toward a correction of those errors in sanitation and other community problems which do not fall directly within the scope of the general practitioner of medicine. Medical men wish to cooperate with health officers in protecting humanity from conditions that bring disease, despair and economic disaster.

We believe that far-seeing public health officials want to be of general service and yet not invade the rights and prerogatives of medical men. I take it that I am stating the attitude of those who ought to be able to control the purposes and practices of public health officials.

We, as a profession, must be willing to cooperate and to aid in every manner the education of the public, so that we become a part of the program which contemplates the control and prevention of disease. But this cooperation should lead to an acceptance of the principle that the continued practice of medicine by individuals is most desirable, and should be rewarded through an economic structure which contemplates a definite place for the medical man. His practice should not be invaded from any source.

It is our task through education and established practice to meet the changing conditions and yet to preserve the all-important relationship of the physician and patient.

I come to you as your President with limited time at my disposal. I have given you but a brief exposition of your affairs. The American Medical Association has grown marvelously until now our interest touches the affairs of the nation, as well as the individual citizen. We aim high when we match our patriotism with the brilliant and lofty humanitarianism of our profession.

Our traditions are not in danger but our interest in the problems of the day requires the direction of the combined wisdom of our leaders, whose immediate interest in the science of medicine separates them into scientific groups, and often keeps them out of the council of the organization.

Medicine needs its men, the lowest to the highest. Let no man hide back of his ego and critically deride the profession. Rather let him become an interested worker, and if he has ideas or talent let him assume leadership. He is always welcome.

With the unbounded ocean of truth yet to discover, why take our present status too seriously? The practice of medicine has always been an art. It has developed into a science; science is systematized knowledge. Knowledge is accumulating; its detail is sometimes overpowering; but clinical medicine, when most efficiently practiced, requires that something of the practitioner which is the highest of all arts.

For those in medicine who feel the urge, there is food for both mind and soul. Human need is the great incentive. Impelled as we are by high purposes, this underlying motive binds us to the living. There is some heaven on earth for every sincere physician. There should be a benediction beyond for all who live within the code.

---

**A Remedy for Fear.**—The one outstanding condition menacing the mental health of every one, at least apparently of every youth, is some form of the emotion of fear. . . . This is reflected in pessimists and sentimentalists who demand a world according to their own wishes. . . . The great remedy for this fear is the attainment of the scientific attitude, together with the insight that in any case one's task is worth doing.—Burnham, W. H.: The Wholesome Personality, New York, D. Appleton & Co., 1932.

# ABDOMINAL PAIN DUE TO HYPOTHYROIDISM

J. WILLIAM HINTON, M.D.
Associate Professor of Surgery, New York Post-Graduate Medical School (Columbia University); Associate Visiting Surgeon, Bellevue Hospital
NEW YORK

Reference has been made by Crile[1] to the association of hyperthyroidism with gastric and duodenal ulcers, but having had an opportunity from Jan. 1, 1928, to Oct. 1, 1931, to observe 444 ulcers in the gastro-enterologic clinic of the Fourth Medical and Surgical Divisions of Bellevue Hospital, my associates and I were unable to detect any patient with an ulcer and a goiter, or with hyperthyroidism. Of the ulcers seen, there were 318 cases in which operation had not been performed and 126 postoperative cases admitted to the clinic. During the past seven years in the thyroid clinics at the New York Post-Graduate Hospital and St. Mark's Hospital, 1,173 cases of goiter have been seen, and in none of these was there a history of pain referable to the stomach or the duodenum. I myself have seen and am familiar with all the aforementioned stomach and goiter cases, and I believe that if Crile's observation were of common occurrence we should have detected it in some of these cases. Verbrycke[2] in a recent article has referred to abdominal pain in association with hyperthyroidism. Any patient suffering from hyperthyroidism of a moderately severe type may have abdominal symptoms manifested in pain, nausea, vomiting or diarrhea, but of course these cases are easily diagnosed, and the abdominal symptoms disappear on correction of the hyperthyroidism.

During the past four years a much more significant observation has been noted in the gastro-enterologic clinic at Bellevue Hospital; patients are frequently referred to the clinic with typical ulcer symptoms and negative roentgen observations, to be treated for an ulcer, and occasionally these patients are found to be suffering from hypothyroidism. As this clinic is a "refer clinic" and the patient is registered only if he has a positive roentgen diagnosis or has been operated on for an ulcer, we have not studied all these cases in detail but have referred them back to the clinic from which they originally came; in a certain selected group, however, in which the patient has been either a hospital employee or a nurse, we have gone into the complaints more carefully and have found that the symptoms suggested a hypothyroidism, and to our gratification there are now six cases under treatment for hypothyroidism in which the complaint was pain referable to the upper part of the abdomen. Brown[3] recently called attention to the effect of hypothyroidism on the gastric and intestinal function, but emphasized constipation as a symptom of the dysfunctioning gland on the gastro-intestinal tract.

The symptoms of hypothyroidism are rather vague and indefinite, and there is no classic group of symptoms for the condition. In the thyroid clinic at the New York Post-Graduate Hospital we have had under observation, during the past fifteen months, seventeen cases of hypothyroidism; the symptoms have been nervousness, irritability, mental depression, instability, dry skin and falling of hair, but pain referable to the upper portion of the abdomen is not the rule in cases with a diminished thyroid secretion. It is the group complaining of abdominal pain, with negative roentgen observations and an associated minus metabolic reading, that will be discussed, and a summary of some of the cases will be given:

Case 1.—A woman, aged 48, a graduate nurse, seen, May 21, 1931, because of pain in the upper portion of the abdomen, nausea and vomiting, gave a negative history. She had been bothered with abdominal pain, nausea and vomiting for twenty years. Numerous physicians had treated her for nervous indigestion and early ulcer of the stomach, but she had become gradually worse. She was not bothered by constipation. Five years before admission, a roentgenologic examination of the gastro-intestinal tract was done for an ulcer but gave negative results. Again one week before I saw the patient, the gastro-intestinal series was negative, but in spite of the negative roentgen observations she was referred to our clinic for treatment. On being questioned, the patient complained of dry skin, scalp trouble and hair falling out. In the mornings she was tired but felt better after she was up for some time. Physical examination gave essentially negative results except for a blood pressure of 90 systolic and 70 diastolic, dry skin and epigastric tenderness. Hypothyroidism was suspected, and the metabolic rate, June 4, was minus 21. The patient was started on thyroxine, one-sixtieth grain (1 mg.) intravenously every week for eight weeks, and then the dose was reduced to 1 mg. every two weeks, with thyroid extract, 1 grain (0.065 Gm.) by mouth, three times a day. The patient has shown a marked improvement, and the metabolic rate, October 15, was minus 8; the abdominal symptoms have almost entirely disappeared, and the other symptoms have greatly improved, but she is still under treatment.

Case 2.—A man, aged 58, seen, May 1, 1929, because of attacks of severe upper abdominal pain for two years, gave a negative history. The patient first had an attack of severe upper abdominal pain, which lasted twenty-four hours, two years before consulting the clinic. During this period he had had three other attacks of severe pain and between the attacks had been troubled by gas, indigestion and heartburn after eating, but on being questioned he complained also of lassitude, dry skin which chapped easily, irritability and constipation. The patient was slightly obese being 30 pounds (13.6 Kg.) overweight, with definite tenderness in the right upper quadrant. The roentgenologic examination of the gastro-intestinal tract gave negative results, but the dye test did not visualize the gallbladder. A metabolic reading revealed a rate of minus 16, and in spite of the observations on the gallbladder the patient was given a diet excluding baked beans, peas, lentils, in fact, all legumes; eggs, fish, especially salmon, bluefish, mackerel and herring; brains, shad roe, fat fish, spicy or fat soups, fatty gravies, highly spiced sauces, pickles, radishes, mustard, pickled meats or fish, pickled fruits, acid fruits, rich pastries, candies or cakes, alcoholic drinks, ice water and sodas, cream and fat, and any other heated fats, as in entrées, pastries and the like. The patient was given thyroid extract, 2 grains (0.13 Gm.) three times a day. He has lost 40 pounds (18 Kg.) has not had any complaints in two years, and was symptom free three months after treatment was started. This patient was not given thyroxine intravenously, but the thyroid by mouth was continued for six months; the metabolic determination in March of this year was minus 6, and the patient stated that he was feeling perfectly well.

Case 3.—A woman, aged 28, a graduate nurse, seen, Aug. 21, 1931, because of abdominal pain after eating, and of nausea and vomiting, gave a negative history. Since she was about 17, she had been bothered with abdominal pain, nausea and vomiting, which had become worse. The pain came on after a heavy meal and was usually worse about 11 p. m., but vomiting gave relief. Ten years ago a roentgenologic examination of the gastro-intestinal tract was done in the Boston City Hospital, and the result was pronounced negative. In spite of medications and a careful diet, her symptoms had become worse, and since May of this year she had had persistent discomfort. In August of this year she had two roentgenologic examinations of the gastro-intestinal tract at Bellevue Hospital which were pronounced negative, but because of the history she was referred to us for an ulcer. On being questioned the patient complained of extreme tiredness in the morning, dry skin, brittle nails, loss of hair, and skin chapping easily. A hypothyroidism was suspected, and the metabolic determination, done August 29, revealed a rate of minus 18. Physical examination revealed a dry skin, epigastric tenderness, pulse 64, and blood pressure 98 systolic and 70 diastolic. The patient is now on thyroxine, one-sixtieth grain (1 mg.) intravenously, every seven days, and thyroid extract, one-half grain (32 mg.) three times a day. Her condition at this time has greatly improved; the abdominal pain has diminished, and she has much more energy.

CASE 4.—A woman, aged 35, seen, Aug. 24, 1931, because of abdominal pain, nausea, vomiting and constipation, gave a negative history. She had had abdominal pain and constipation since adolescence, but the conditions had become gradually worse during the past ten years. Because of abdominal pain she was unable to eat heavy, fried or acid foods, and for the past three or four years she had had constant nausea after meals, and frequently vomited if she ate a heavy meal. There was less pain and discomfort after very light meals or when the stomach was empty. She even had no night pain, but constipation was very marked, and only with strong cathartics was a bowel movement possible. She stated that she had been treated for an ulcer of the stomach for several years but said that the condition had gradually grown worse. On being questioned, she complained of mental depression, a very poor memory and extreme nervousness; also, her hair was falling out, the skin was dry and chapped easily, and she objected to cold weather. She was undernourished, weighing 104 pounds (47 Kg.); her best weight was 125 pounds (57 Kg.). The blood pressure was 80 systolic and 60 diastolic, and the pulse was 70. The right kidney was palpable and movable; there was slight epigastric tenderness; the skin was dry, and the reflexes were normal. A diagnosis of hypothyroidism was made, and the basal metabolism, August 25, was minus 17.

The patient was informed of her trouble, and then she volunteered the information that a recent roentgenologic examination of the gastro-intestinal tract had been done; she had been told that a small tumor of the stomach existed and that she needed an immediate operation. Roentgenologic study of the gastro-intestinal tract was repeated and pronounced negative. The patient was given thyroid extract, 1 grain (0.065 Gm.) three times a day, and thyroxine, one-sixtieth grain (1 mg.), intravenously for six doses. October 25, she had gained 6 pounds (2.7 Kg.), and was not tired, nervous or depressed. The constipation had shown some improvement, and the pain, nausea and vomiting had practically disappeared, but she is still under treatment.

The symptoms in the foregoing cases were so suggestive of an ulcer that all diagnostic methods and treatment had been directed to the gastro-intestinal tract. The conditions found were probably due to a hypoperistalsis with a pylorospasm and retention of undigested food in the stomach; after the patient vomited the retained food, or the stomach slowly emptied, the symptoms were relieved.

The other patients gave essentially the same history and are improving on thyroid medication.

## COMMENT

It is my desire to call attention to hypothyroidism as a factor in producing abdominal pain, and to emphasize that patients giving negative roentgen evidence of changes in the gastro-intestinal tract, the gallbladder and the genito-urinary region, as well as negative results in the other laboratory procedures, may in a small percentage of cases be suffering from hypothyroidism; in this group with negative roentgen observations a metabolic determination should be done before any treatment is instituted or before the patients are submitted to an exploratory laparotomy, as occasionally a diagnosis will be established and the symptoms relieved with thyroxine and thyroid extract, the patient being saved a needless operation. There seems little question that, in the past, probably quite a few exploratory procedures have been undertaken with negative results or at least with symptoms persisting after the operation, in which case the entire trouble was referable to the thyroid gland.

I do not want to leave the impression that all patients with abdominal pain in which the roentgenologic observations are negative are suffering from hypothyroidism, for such is not the case; but if this condition is borne in mind a definite diagnosis can be made in a small percentage of cases, and the individual can be benefited by the proper medication. On the other hand, a patient may have a minus metabolic rate and a definite intra-abdominal lesion which will need either medical or surgical treatment. Of course, no benefit could be expected from the abdominal pain by treating the hypothyroidism and neglecting the other condition that is actually causing the pain. I have such a case under observation at this time; the patient is waiting to have a cholecystectomy in the near future for the relief of abdominal pain, but her symptoms of lassitude, constipation, irritability and mental depression have improved on thyroxine intravenously and thyroid extract by mouth.

# TREATMENT OF OLDER DIABETIC PATIENTS WITH CARDIOVASCULAR DISEASE

SOLOMON STROUSE, M.D.
SAMUEL SOSKIN, M.D.
LOUIS N. KATZ, M.D.
AND
S. H. RUBINFELD, M.D.
CHICAGO

In the past few years, arteriosclerosis and heart disease have become increasingly prominent as causes of death in diabetes mellitus. A recent article by Joslin [1] starts with the words "Every other diabetic now dies of arteriosclerosis, and the percentage of such cases has been rapidly rising." In the period between 1894 and 1914, 15 per cent of the total number of deaths of diabetic patients in Joslin's series of 342 deaths were due to arteriosclerosis; in the period 1926-1929, the death rate from arteriosclerosis had risen to 48 per cent. The coma death rate, during the same period, had dropped from 61 per cent to 11 per cent. The organ most frequently involved by the arteriosclerotic process in Joslin's series is the heart (43.1 per cent of all arteriosclerotic deaths). Similar statistics have been published by Warren,[2] Wilder,[3] Root and Graybiel,[4] Blotner [5] and Nathanson.[6] Coronary sclero-

sis, coronary thrombosis, infarction of the heart and varying degrees of myocardial degeneration are common pathologic manifestations in the group of diabetic patients who die of cardiac complications.

Careful analysis of the published statistics seem clearly to involve the disease diabetes as an etiologic factor in the production of arteriosclerosis. A statistical study by Levine[7] led him to believe that diabetes is a common cause for coronary thrombosis. In Levine's group of 145 cases, approximately 23 per cent showed glycosuria. It is, of course, recognized that the prolongation of life brings more individuals to the arteriosclerotic age, but comparative statistics and autopsies performed on diabetic and nondiabetic patients show that the incidence of arterial disease in the diabetic is considerably greater than in the nondiabetic patient. Nathanson has studied two series and finds that in 100 autopsies on diabetic patients 41 showed severe coronary disease. Above the age of 50 the incidence of coronary disease was 52.7 per cent, as compared with 8 per cent in an even larger series of nondiabetic patients of the same age.[8] Furthermore, in diabetic patients the incidence of coronary disease in the female is almost as high as in the male, as compared with the ratio of 1:3.5 in Levine's nondiabetic series. But perhaps the most convincing evidence that diabetes is an etiologic factor in arteriosclerosis is furnished by a study of the frequency of arteriosclerosis in younger diabetic patients. Shepardson[9] emphasizes the incidence of arteriosclerosis in diabetic patients under 40. The minimum duration of the disease in these cases was five years. It is true that the evidence furnished by Shepardson's studies is not final, as his conclusions are based almost entirely on evidence furnished by roentgen studies of the arteries during life. Nevertheless, of fifty patients studied with an average age of 23.4 years and an average duration of the disease of 6.9 years, he found peripheral arteriosclerosis in 36 per cent of his patients with an average age of 25.4 years and an average duration of the disease of 7.6 years. Joslin,[1] too, has called attention to the incidence of arteriosclerosis in the young whose diabetes has lasted from five to ten years.

The change in the cause of diabetic death from coma to coronary disease definitely followed the introduction of insulin. Insulin has made coma an almost completely preventable cause of death, as is witnessed in the Joslin series, in which the rate changed from 61 to 11 per cent. Yet a paradoxical situation now has arisen in that insulin has been accused of being responsible for some of the cardiac deaths in diabetes. The evidence involving insulin is both clinical and experimental. Turner[10] and Modern[11] have discussed the "heart-pain" due to insulin shock and hypoglycemia. Middleton and Oatway[12] thoroughly reviewed the literature on the experimental aspects of this subject and themselves added further studies to show that insulin shock presents a real hazard to the heart. They strongly urge that insulin shock and hypoglycemia should be avoided in the presence of any type of myocardial involvement. Parsonnet and Hyman[13] described the development of the stenocardial syndrome following the administration of insulin to diabetic patients with coronary thrombosis. Their communication is particularly important because in the four cases reported by them no symptoms of coronary disease were present before the administration of insulin, and in only one patient, a very large overweight woman, had there been any previous suggestion of heart disease. These authors also mention three other diabetic patients who developed milder symptoms of angina without electrocardiographic evidence of coronary thrombosis, following the use of insulin. Blotner[5] concluded that acidosis and a rapid lowering of the blood sugar level with insulin play contributory parts in inducing mortalities in coronary thrombosis.

The question of proper therapy of the diabetic patient with vascular disease has received very little experimental study. As a result of their experiences with insulin shock and hypoglycemia, some authors, as Middleton and Oatway,[12] advise caution in the therapeutic use of insulin in such cases. But granting that insulin shock and hypoglycemia are dangerous, we do not know whether the continued use of insulin as a therapeutic procedure in doses small enough to avoid abnormally low blood sugar levels carries with it a similar menace to the cardiovascular system of this class of patients. The more rigid control of the metabolic manifestations of diabetes, made possible by insulin, has emphasized the clinical observation that during such treatment the patient may grow worse as the diabetes improves. The lack of experimental evidence concerning this increasingly important therapeutic problem has led us to the present investigation. Since all previous experimental work dealt almost entirely with acute insulin shock or with the effects of acutely produced hypoglycemia, we felt that it was necessary to emphasize the long term, therapeutic experiment.

## PROCEDURE

We studied seven patients with diabetes and clinical evidence of coronary sclerosis or angina pectoris. All these patients were placed in the Max Pam Metabolism Unit of the Michael Reese Hospital under conditions approaching laboratory control. Their cardiac status varied from complete well being to mild congestive failure while at rest. Their diabetic status also varied from mild to moderately severe. Cases of mild and severe Heberden's angina pectoris were included. Each patient was kept for from two to four weeks on a given diet which permitted his accustomed high blood sugar level and glycosuria, no attempt being made to control the diabetic manifestations to a greater extent than was usual with that patient. This period was followed by a similar period in which the diet remained unchanged but insulin was used in therapeutic doses (from 30 to 70 units daily). The blood sugar was kept at a low normal level and at no time was sufficient insulin given to produce persistent hypoglycemia. In other words, during the latter period, these patients received a moderately strict treatment for their diabetes without regard to their cardiovascular status. We wish to emphasize again at this point that the nature of these experiments was distinctly therapeutic; we wanted to learn the reaction of these cardiovascular diabetic patients to treatment aimed entirely toward the improvement of their diabetes.

In addition to the foregoing experiments a set of acute experiments was performed in which each patient, after a careful period of observation, received one large dose of insulin. The results of the acute experiments form a basis for comparing our work with previously reported studies. The observations made after the insulin injection included the effect of the intravenous injection of dextrose.

## RESULTS

The results summarized here are concerned chiefly with observations on the heart. More comprehensive studies of the cardiovascular system are projected. The complete details and the experimental data collected from this series of patients on changes in blood pressure, pulse rate, cardiac rhythm, electrocardiogram and metabolism will be reported elsewhere. In the present report we wish to make a brief summary, and since the results following the acute experiments are the more striking, they will be given first.

*Objective Phenomena.*—After insulin the blood pressure tended to fall, the heart rate to increase, extrasystoles of various origins were induced, and in one case a run of paroxysmal auricular fibrillation was initiated. Some or all of the typical symptoms of insulin shock were observed, and in two cases typical attacks of angina pectoris were precipitated.

The electrocardiogram showed, in brief, a decrease in amplitude, slight prolongation and increased slurring of the Q-R-S complex, increase in the deviation of the S-T segment in a direction opposite to the major initial complex, and a prolongation and deviation of the T wave in a direction opposite to the major initial complex, occasionally going so far as to produce a change in its direction. We interpreted these changes as indicative of the development of intraventricular block. Intravenous administration of dextrose always alleviated the symptoms and restored the electrocardiogram to its original contour.

These results can be correlated with a previously reported inversion of the T wave caused by insulin. The fact that the T wave became more positive or changed from a negative to a positive deflection when the initial complex was inverted shows that the inversion of the T wave in such cases is a sign of slowing in intraventricular conduction. In one case in which a striking attack of angina was precipitated, changes in the electrocardiogram similar to those described during such attacks (Wood, Wolferth and Livezey;[14] Feil and Siegel[15]) were noted even before the symptoms appeared.

The effects observed in the therapeutic experiments were similar to but of lesser magnitude than those just reported. The blood sugar level was maintained below that to which the patients were accustomed, and the doses of insulin used did not produce persistent hypoglycemia. A constant slowing of heart rate occurred, and extrasystoles and electrocardiographic changes similar to those described in the acute experiments were noted. The magnitude of the electrocardiographic deviations in the therapeutic experiments did not depend entirely on the absolute level at which the blood sugar was maintained. The length of time over which insulin was administered and the extent of the change from the accustomed blood sugar level to the new level seemed to be important factors.

*Subjective Phenomena.*—In all patients particular attention was paid to the subjective symptoms during the therapeutic experiments. It is known, of course, that patients may have mild anginal attacks without tangible objective signs, and it is not always easy to decide whether pain is truly anginal in type. Almost invariably during the period of insulin administration the patients complained of a decreased sense of well being. The usual complaints were weakness, prostration, dizziness, nervousness, palpitation, precordial pain and constriction and, in some cases, typical angina pectoris. One patient refused to continue on the insulin period as he said that he "felt bad all the time." It was interesting to note that these symptoms occurred at blood sugar levels compatible with complete comfort in younger diabetic patients. The interpretation of symptomatology uncontrolled by such objective data as we collected would be difficult. But in view of the fact that the patients' complaints and the objective manifestations were so well correlated, the symptoms must be accepted as important.

One case, of a woman in her late fifties, is of unusual interest and is important for two reasons. First, she had mild diabetes, frequent attacks of angina pectoris associated with paroxysmal auricular fibrillation, and no evidence of coronary thrombosis. This unusual combination made it possible to correlate the subjective complaints with the objective demonstrable phenomena. Second, because of the mild diabetes she was given no insulin at any time during the therapeutic experiment, her diabetes being controlled by diet alone. This made it possible, in reviewing our results, to evaluate the direct effects of insulin on the heart as opposed to the effects of the metabolic changes induced by insulin.

On a diet of protein 50, fat 100, carbohydrate 50, which for purposes of comparison we shall call a low carbohydrate diet, she had frequent attacks of angina pectoris and paroxysmal auricular fibrillation. During this time she would have attacks even when at rest in bed in her room. The substitution of an isocaloric comparatively high carbohydrate diet of protein 50, fat 50, carbohydrate 160 caused an immediate and complete cessation of the attacks. This is especially significant, since her fasting blood sugar was on the average only about 20 mg. per hundred cubic centimeters higher during the high carbohydrate diet than during the low carbohydrate diet. On the latter diet she remained in bed without protest. In fact, during one experimental period of low carbohydrate diet, her attacks became so severe and frequent that this diet had to be discontinued. In marked contrast to this is the difficulty we experienced in keeping her in bed during the high carbohydrate regimen. Indeed, her only attack while on the high carbohydrate diet was precipitated when she walked down a long hospital corridor and up several stairs in order to use a telephone. The contrasting effects of the two diets were confirmed by repetition. This case showed, in a most striking way, that all the phenomena following the use of insulin noted in the other therapeutic experiments could be reproduced by the use of a low carbohydrate diet alone.

The acute experiment with insulin on this woman yielded completely confirmatory results. It was carried out after a prolonged period of high carbohydrate diet. At the time of the acute experiment she was in excellent condition, having had no anginal attacks nor any abnormal cardiac rhythm for a month. Fifty minutes after the administration of 25 units of insulin subcutaneously, she complained of precordial pain, which soon radiated to the left arm. Simultaneously with the appearance of angina there developed a paroxysm of auricular fibrillation interspersed with ventricular extrasystoles. This irregularity was shown by the electrocardiogram taken at the moment she first complained. It is interesting to note that the typical electrocardiographic changes usually seen during angina pectoris appeared in the records taken during this experiment even before the pain developed.

---

[14] Wood, F. C.; Wolferth, C. C., and Livezey, Mary M.: Angina Pectoris, Arch. Int. Med. **47**: 339 (March) 1931.

[15] Feil, H. S., and Siegel, M. L.: Electrocardiographic Changes During Attacks of Angina Pectoris, Am. J. M. Sc. **175**: 255 (Feb.) 1928.

Thirty-five minutes after the beginning of this induced attack the patient was given 3 ounces of orange juice and 3 teaspoonfuls of cane sugar by mouth, followed by an intravenous injection of 50 cc. of 50 per cent dextrose solution. Five minutes after the injection was completed, the pain had disappeared and the electrocardiogram showed a regular but rapid rate, a sinus tachycardia. The auricular fibrillation soon returned and lasted until the following morning, but no further pain was experienced. The similarity of effects during the acute and the therapeutic experiments on this patient is apparent.

### COMMENT AND SUMMARY

The results obtained in the acute experiments agree with those previously reported, as to the deleterious effects of insulin hypoglycemia on the heart. The risk incurred by insulin "shock" in older diabetic patients with cardiovascular disease need not be enlarged on.

Our long term therapeutic experiments show that insulin, in the usual therapeutic doses, presents a similar hazard to the hearts of such patients. The objective data obtained from our patients can be closely correlated to their subjective complaints and indicate a real basis for the latter. This accords very well with the previously mentioned clinical observation that such patients may grow worse as their diabetes improves and may explain why it is so difficult to frighten or cajole such a patient into following a regimen strict enough to maintain his blood sugar at a level ordinarily considered normal. It is possible that, for such patients, the higher blood sugar levels usually found do represent the "normal" or perhaps optimum value, as far as their cardiovascular state is concerned. Smith, Gibson and Ross,[16] among others, have shown the beneficial effects of carbohydrate administration in heart failure in the nondiabetic patient. The deleterious effects of the therapeutic use of insulin in our cases did not seem to depend so much on the absolute level of blood sugar attained as on the extent of the change from the accustomed to the new blood sugar level and on the length of time over which the insulin was administered.

The case described, in which the results obtained with insulin were reproduced by the use of a low carbohydrate diet alone, indicates that insulin is not the only factor to be considered if one is to avoid endangering the damaged heart. The blood sugar level and the carbohydrate available for the use of the diseased myocardium must be important and may be the essential factors involved. The diet is therefore of paramount importance whether the patient is given insulin or not.

The increasing incidence of heart disease as the cause of death in diabetic patients should serve as a warning that the needs of the impaired myocardium must not be forgotten in efforts to control the metabolic manifestations of diabetes.

# ULCERATIVE COLITIS DUE TO CHRONIC INFECTION WITH FLEXNER-Y BACILLUS

## REPORT OF CASE WITH CURE BY AUTOGENOUS VACCINE

THOMAS T. MACKIE, M.D.
NEW YORK

The relative frequency and severity of chronic ulcerative colitis and the difficulties of its successful treatment warrant the report of instances that may throw light on the condition. Experience indicates that it is a disease without distinctive tissue changes, which may be associated with a variety of different organisms. Since the Great War several English observers have emphasized the apparent relationship to antecedent amebic or bacillary dysentery, especially when the acute phase has been improperly or insufficiently treated.[1] In certain instances the chronic condition is attributed to the presence of secondary invaders in the wall of the bowel;[2] in others to the persistence of the dysentery bacilli themselves.

The possibility that at times the latter organisms may play an important rôle meets four important objections. The onset of chronic ulcerative colitis is usually insidious and not apparently related in time or in fact to an antecedent acute intestinal disease. The appearance of cases is sporadic. The dysentery bacilli can rarely be recovered from these cases. And, finally, the disappearance of epidemic dysentery, except under the unusual lack of sanitation associated with war conditions, has led to the widespread belief that the disease has become a rare condition in the more settled and highly developed parts of the world.

Clinically, acute bacillary dysentery may be roughly divided into two groups, the Shiga infections, usually associated with a severe illness, and those due to Flexner-Y and other strains, which characteristically induce only a mild condition which may be so trivial as to escape particular notice. Zinsser[3] calls attention to the fallacy of considering the disease one that occurs only in epidemic forms. Certain of the dysentery bacilli may cause only mild intestinal inflammations and even simple diarrheas. It is probable, moreover, that many of these transitory diarrheas occurring sporadically and in small groups may depend on unrecognized infection by these organisms. During the war, 75 per cent of the mild cases were found to be due to the Flexner-Y bacilli. The Y bacillus particularly has been found in cases of infantile diarrhea. Furthermore, the persistent carrier of these organisms is generally in fairly good health and able to carry on his occupation until subjected to adverse conditions which may precipitate a further recurrence. Not only, therefore, may attacks of Flexner dysentery be so mild as to escape comment at the time, but, because of the lack of severity, little if any importance may be attached to them in the study of a later chronic disease.

Investigations carried out during the World War indicated that the Flexner group is universally dis-

tributed, but that Shiga infections are usually acquired only in tropical or subtropical countries. In Belgium the epidemics in the armies were almost entirely due to the Flexner-Y group.[4] Recently the disease has been reported to be endemic in the southern part of the United States and to be increasing in frequency.[5]

The recovery of these organisms from cases of chronic ulcerative colitis is not usual, and this has led to the impression that although the disease may follow on acute bacillary dysentery, the relationship between them is indirect. The excretion of the bacilli, however, by the chronic carrier is apt to be intermittent, and, in fact, intermittence is described as one of the characteristics of long-standing infection. The organisms may be found in the stools for one or two days in succession, to be followed by an interval of four or five weeks when all bacteriologic examinations of the feces are negative.[6] Martin and William[7] found that only 15 per cent of the initial stool cultures from cases of chronic dysentery were positive. It has further been shown that the Flexner bacilli are almost twice as difficult to recover as are the Shiga organisms. The difficulty of demonstrating the dysentery bacilli in the excreta emphasizes the importance of swab cultures from the floor of the ulcerated areas in the colon and rectum. Positive cultures may be obtained by the latter method when the stools are persistently negative,[8] but a single negative culture cannot be accepted as evidence sufficient to exclude a dysenteric infection. While the factor of intermittence may therefore play a large part in the difficulty of demonstrating the bacilli, certain of their biologic characteristics are of importance as well. Their viability in stale stools is much limited, and in scanty infections, unless a selective medium is used, they are easily overgrown by other organisms.

Agglutination tests, when stock cultures are used, cannot be depended on as a means of diagnosis or as an accurate method of eliminating the possibility of infection. Fildes[9] found that only 60 per cent of the patients with chronic, convalescent or cured Shiga dysentery who were still excreting the bacilli possessed agglutinins in significant amounts for these organisms, and similarly among the Flexner cases only 20 per cent gave significant agglutination reactions.

While the relationship between chronic dysentery and chronic ulcerative colitis is not direct or evident in many instances, neither is the distinction between them well defined. The differentiation has necessarily been based on the results of culture and agglutination reactions which cannot be accepted as definite unless consistently and repeatedly negative. Hurst[10] has emphasized the fact that the two conditions are indistinguishable in appearance both at autopsy and in life through the sigmoidoscope. Menon[11] in India found that 60 per cent of fatal cases of chronic colitis or chronic diarrhea of indefinite origin present lesions with a strong morphologic resemblance to those of chronic dysentery. Lockhart-Mummery[12] also states that the chronic conditions following on acute amebic or bacillary dysentery do not differ in any way from the ordinary cases of ulcerative colitis endemic in England and the United States. Bastedo[13] has suggested the probability that many of them, if properly studied, would fall within the group of bacillary infections.

The lesions of chronic dysentery are restricted to the lower half of the colon and characteristically consist of serpiginous ulcers. They are distributed transversely to the long axis of the intestine on the free edge of the transverse folds of the mucosa. The edges are usually undermined and ragged, and the base is formed by granulation tissue. Often they are intercommunicating. The intervening mucosa is usually hyperemic and bleeds easily on contact. Healing is accompanied by scarring and frequently by pigmentation.

There is a widespread impression that the acute phase terminates the disease and that chronic dysentery due to the persistence of the bacilli is a rarity. The infection may persist, however, with remissions of varying length for from one to several years, as commonly happens with amebic disease. It is variously estimated that from 2 to 5 per cent of the acute cases become chronic.[14] Fletcher and Mackinnon[6] found 52 chronic carriers of Flexner and 13 of Shiga bacilli among 935 soldiers convalescent from bacillary dysentery. More than 20 per cent of the convalescents from whom Flexner organisms were recovered, and all the Shiga cases carrying bacilli, became persistent carriers. Most of the chronic cases in this group had presented recurrent attacks over long periods of time, and relapses were frequent in these long established infections. In a study of chronic dysentery in Peiping, Smyly[8] recovered B. dysenteriae from fifty-six patients. Mannite fermenting bacilli were found in 54 per cent, Shiga bacilli in 32 per cent, and the remaining 14 per cent had double infections. Castellani,[15] Hudson,[16] Maggi[17] and Bastedo[13] have all reported chronic cases due to continued infection by members of the mannite fermenting group, usually the Flexner bacilli, and recently in New York Winkelstein[18] recovered Flexner or Shiga organisms from four cases of chronic ulcerative colitis.

Vaccines, both stock and autogenous, have been used from time to time in the past, but often with contradictory or equivocal results. Manson-Bahr and Gregg[19] summarize the failures by stating that the ineffectiveness of this form of treatment depends on the minor rôle which the dysentery bacilli play in the later stages of the disease. Some observers hold that vaccinotherapy may be definitely harmful, and others do not recommend it. Van Nitsen[20] found a higher mortality among a group of cases treated by a mixed vaccine of Shiga and Flexner bacilli than in a similar series treated by medical measures alone. At times, vaccines are said to cause dangerous focal reactions,[21] and Rogers[22] has reported massive gangrene of the bowel and exacerbation of the existing condition. This he attributes to the endotoxin of the Shiga bacilli and to the possible development of a negative phase. On the other hand, autogenous vaccines are said to have little effect.[23]

However, there are numerous reports of the successful use of this form of treatment.[24] Nolf found that intravenous injections in increasing doses from 1 to 10 millions gave the best results in chronic Flexner infections. Others using this method, but in doses up to 60 millions, report that rigors, pyrexia and marked clinical improvement resulted. The subcutaneous route is said to be less effective, but recently a stock vaccine which is agglutinated by the patient's serum has given excellent results.

It would appear, therefore, that the conflict of opinion depends on the selection of cases, the type of vaccine used, the dosage, and the duration of treatment. Success is to be expected only in the individuals having a continued infection by the dysentery bacilli and not in the cases of remote secondary infection. In many instances in which the results have been unfavorable or inconclusive the dosage was small, the intervals long, and the treatment not long continued. Autogenous vaccines have not been fully tested, but the weight of evidence indicates that this form of therapy has a definite place and usefulness, that the vaccine probably should be autogenous, and that it should be continued in adequate dosage over a considerable period of time.

## REPORT OF CASE

A clergyman, aged 64, first seen in 1927 because of attacks of syncope and dyspnea on exertion, was slightly overweight, plethoric in appearance, and presented a moderate cardiac enlargement. The blood pressure was 150 systolic and 90 diastolic. The electrocardiogram showed a moderate left-sided preponderance. The blood count at this time showed: hemoglobin, 100 per cent; red blood cells, 4,800,000; white blood cells, 14,800; polymorphonuclears, 68 per cent; lymphocytes, 30 per cent; eosinophils, 2 per cent. He progressed satisfactorily on small doses of digitalis and restriction of activity.

In June, 1928, he was admitted to St. Luke's Hospital complaining of a slight purulent discharge from the rectum and the occasional presence of small amounts of blood in the stools. A fistula in ano was found extending upward for an inch and a half from the sphincter, just deep to the mucous membrane. The tract was excised and recovery was uneventful.

He was not seen again until May, 1929, when he returned stating that for the past two months he had had "colitis." This was characterized by profuse watery diarrhea containing flocculent material but no gross blood or mucus. On the rare occasions when the stools were formed, small amounts of mucus were present but never blood. He had been afebrile but suffered more or less from lower abdominal pain and especially from exhaustion and prostration. At this time a history was obtained which had not been elicited on the previous contacts with him.

In 1923, while on a trip around the world, he had a severe attack of diarrhea in Shanghai. He was ill for ten days but did not have fever. Shortly afterward on reaching India, he had a recurrence which kept him in bed for two weeks and necessitated alteration of his itinerary. Again the attack was afebrile. The stools were very loose, yellow and numerous. During the next two years in New York attacks of diarrhea recurred at frequent intervals, and he stated that he seldom had an entirely normal stool. He was able to carry on his parish work, however. In 1925, while on a trip through the Mediterranean, he had another severe attack in Jerusalem, lasting a week, and subsequently another recurrence of the same duration in Athens. The stools again were watery and the attacks afebrile but accompanied by much prostration.

During the next four years, periods of diarrhea recurred at frequent intervals but never of sufficient severity to cause him to seek medical advice. The longest free interval was of only a few months' duration, and during this period he became progressively lacking in energy and strength.

In May, 1929, he was given camphorated tincture of opium, bismuth subcarbonate, and a bland low residue diet. These measures were only partially successful, since omission of the medication was immediately followed by recurrence of the diarrhea. He showed some loss of weight, appeared a little pale and was obviously worn out. The cardiac diameters were slightly increased and the blood pressure had fallen to 124 systolic and 80 diastolic. Definite tenderness was present over the course of the descending colon and the sigmoid. Rectal examination was negative. Roentgen examination of the colon showed the barium sulphate to flow freely through to the cecum. No evidence of a malignant condition was found, but the sigmoid and the lower portion of the descending colon were quite smooth, showed few haustrations, and were definitely spastic. The hemoglobin was 83 per cent and the red cell count 3,480,000. The white count was 8,900 and the differential formula: polymorphonuclears, 73 per cent; lymphocytes, 23 per cent; eosinophils, 3 per cent, and monocytes, 1 per cent. The stained film showed anisocytosis and poikilocytosis with occasional polychromatophilic cells. The platelets appeared to be reduced in number.

The patient was readmitted to St. Luke's Hospital under the care of Dr. Lewis F. Frissell. A week after the previous examination the hemoglobin was 92 per cent and the red blood count 3,200,000. Gastric analysis after the test meal showed free hydrochloric acid to be absent and total acid 4. A roentgen examination of the gastro-intestinal tract showed no evidence of a malignant condition. Stool examination for monilias was negative by smear and culture. No amebas were present and the test for occult blood was negative. Culture of the stool for Flexner and Shiga bacilli was negative. The patient was immediately placed on a liver diet and a week later on Eli Lilly Liver Extract and hydrochloric acid. Daily colon irrigations were given, at first of sodium bicarbonate and later of saline solution. The return was usually clear except for the occasional presence of mucus in small amounts. He was allowed to return to his home after two weeks, but although the diarrhea had stopped the stools continued loose and unformed.

In September, 1929, he reported that his condition seemed satisfactory and that he had been well except for occasional upsets associated with return of the diarrhea following omission of hydrochloric acid.

In November, 1929, however, the diarrhea returned acutely and persisted. The stools were watery and foamy, with considerable amounts of mucus but no blood. Physical examination at this time showed definite atrophy of the papillae of the tongue but no aphthae. There was tenderness high up in the rectum on digital examination but otherwise there were no new manifestations. The hemoglobin was 99 per cent, the red cell count 4,180,000, and the white blood count 8,200 with 73 per cent polymorphonuclears. The stained smear showed anisocytosis, poikilocytosis, and occasional polychromatophilic macrocytes. There was no subjective or objective evidence of subacute combined sclerosis. Because of the primary anemia, the frothy diarrhea, and the absence of signs of involvement of the spinal cord, he was admitted to the Presbyterian Hospital for treatment of sprue. A second gastric analysis following the administration of histamine showed free hydrochloric acid absent and total acidity none. Reexamination of the colon by x-rays presented essentially the same picture as on the former occasion. Stool examinations were consistently negative for amebas and other parasites. At sigmoidoscopy the upper part of the rectum contained some mucopurulent exudate; the mucosa was markedly hyperemic and showed numerous ulcers, the largest 0.5 cm. in diameter. The patient was placed on the diet then in use for the treatment of sprue: the quantitative elimination of wheat, rice, sugar and potatoes with the substitution of banana flour for the carbohydrates. During the period of observation the temperature was normal and he was discharged to continue the diet, liver extract and hydrochloric acid at home.

These measures did not alter the character or the intensity of the diarrhea, and a month later he was readmitted because of the increasing severity of this symptom and the development of tenesmus with the passage of large amounts of pus and mucus. A second sigmoidoscopic examination showed multiple superficial ulcerations with slightly hemorrhagic borders, covered with a foamy yellowish-white cap. They were most numerous in the lower part of the rectum. The mucous membrane between the ulcers was not hyperemic, and there was no evidence of undermining of the edges. Smears taken through the sigmoidoscope failed to reveal amebas, but cultures similarly made grew out a practically pure culture of Flexner-Y bacilli.

An autogenous vaccine was made at once and given in increasing doses three times a week until the patient was receiving a billion bacilli at each injection. This was continued for several months. There was an immediate improvement in all the bowel symptoms, and within two weeks of the initiation of this treatment the diarrhea ceased and the stools became normal.

In November, 1930, he returned, complaining of constipation and the occasional appearance of a slight mucopurulent discharge from the rectum when this symptom was especially marked. A stool culture for the Flexner bacilli was negative, but another course of six injections of the autogenous vaccine was given.

He was seen again in November, 1931. There had been no recurrence of diarrhea since the initial vaccine treatment twenty-two months previously. The rectal discharge had not returned, the bowel function was normal, and the stools were free from any abnormality. Reexamination of the colon by x-rays showed a smooth outline of the sigmoid with approximately normal haustrations proximal to it. No indication of irritability was noted. Sigmoidoscopic examination revealed a normal appearing mucous membrane; ulceration and hyperemia were not present. Cultures taken through the sigmoidoscope from the mucosa of the sigmoid region and the rectum were negative for B. dysenteriae. The hemoglobin was 98 per cent, the red cell count was 4,360,000, and examination of the stained smear showed a few macrocytes and microcytes and a moderate degree of anisocytosis. The average cell diameter, as measured by the Eve halometer, was 7.8 microns.

## COMMENT

This case is presented because of the rapid and complete response to treatment by an autogenous Flexner-Y vaccine, and because of the cure proved by symptoms, sigmoidoscopy and cultures twenty-two months after the beginning of specific treatment. It illustrates some of the difficulties that may occur in the identification of an etiologic factor in a case of chronic ulcerative colitis. Stool cultures were negative, yet subsequently B. dysenteriae was recovered on direct culture from the floor of the ulcer through the sigmoidoscope. The history given by the patient again points to the important rôle a mild attack of bacillary dysentery may play in the individual's later health. Despite the apparent continuity of intestinal symptoms during the years from the initial attack in 1923 to the time the diagnosis was established in 1930, the patient attached little importance to them and considered merely that he had an easily disturbed gastro-intestinal tract. The facts that have been presented in this connection were not obtained as part of a connected story but for the most part as the result of direct and leading questioning.

At the time the bowel symptoms became prominent, the patient was found to have an achlorhydria and a primary anemia associated with the diarrhea. The latter symptom was attributed to the primary anemia and was expected to yield to the treatment of this condition. When it continued in spite of hydrochloric acid and liver extract in adequate and continued dosage, and when the stools presented the appearance so characteristic of sprue, together with the lack of evidence of subacute combined sclerosis, the diagnosis of sprue was seriously entertained.

Strauss[25] and Schroeder[26] have shown that altered functions of the gastric mucosa and of the hematopoietic system may occur in association with chronic dysentery. These cases have been classified in three clinical groups.[27] Of the chronic carriers, 60 per cent showed hypochlorhydria, some abnormality of the stools, and a reduction of hemoglobin values. Others showed hypo-acidity, a definite chronic colitis sometimes with ulceration, and changes in the blood picture. The third group presented a frank recurrent dysentery and colitis, intestinal ulceration, and cachexia. In 1912, Castellani[15] reported three cases of chronic Flexner dysentery in which there was an associated clinical picture indistinguishable from sprue although occurring in a locality in which sprue was not considered endemic. Recently a detailed study of the anemias associated with chronic dysentery has been made at Peiping.[28] In the group as a whole, all the features said to be characteristic of pernicious anemia have been observed. The conclusion is reached that the cause of the anemia is not always the same, but the most important factors in its development seem to be the nutritional disturbances resulting from a faulty diet and a process that interferes with normal nutrition. Gastric anacidity, loss of blood, and infection are considered to be important contributory factors. In the case here reported it has not been possible to demonstrate a dietary deficiency, although the primary anemia seemed to develop during the period of observation. The other factors of anacidity and infection were both present. Elimination of the infection, however, has not altered the condition of the blood.

## SUMMARY

1. The Flexner-Y group of dysentery bacilli may cause sporadic cases of mild diarrhea and dysentery. The occurrence of these cases does not require the presence of epidemic conditions.

2. A significant number of these individuals may become persistent carriers and develop ulcerative lesions of the lower part of the bowel, even though the initial acute attack may have been very mild.

3. The lesions of chronic bacillary dysentery differ in no respect from those encountered in many of the cases of so-called chronic ulcerative colitis.

4. Intermittence of the excretion of the bacilli is one of the characteristics of chronic Flexner bacillus infection, and repeated cultures over a period of weeks may be necessary to demonstrate them.

# BACILLURIA UNDER KETOGENIC TREATMENT

ANSON L. CLARK, M.D.
ROCHESTER, MINN.

In a discussion on the persistence with which attempts to dislodge the colon bacillus from the urinary tract are defeated, Barborka reminded me that the urine of patients who are receiving a diet high in fat and low in carbohydrate is considerably acidified. Shohl and Janney,[1] a number of years ago, demonstrated that growth of colon bacilli was inhibited in urine of which the acidity was as great as $p_H$ 4.6 or 5.0, or alkalinity as much as $p_H$ 9.2 or 9.6.

In October, I [2] reported the results in two cases of bacilluria of Escherichia coli type, in which the ketogenic diet was given. Since that time, the treatment has been applied in several additional cases of persistent bacilluria, and the patients have been under observation long enough to allow the results to be evaluated.

In the accompanying table is a summary. Several notable features emerged from observation of these cases:

1. The general condition of the patient must be such that he can endure the alteration in his diet. A patient who is able to take a moderate amount of exercise is a far more satisfactory subject for this type of treatment than one who is necessarily confined to bed.

2. Cooperation of the patient is absolutely necessary. In cases 2 and 6 in the table the patients were not cooperative, and the results obtained, as judged by the $p_H$ of the urine, were correspondingly disappointing.

3. The patient must be able to digest and assimilate fats. This was clearly demonstrated in case 15; the patient apparently was unable to prepare the ingested fats for assimilation. He had undergone resection of the stomach, but whether this fact is relevant to his inability to rid himself of bacilluria cannot be stated.

4. The normal intake of fluid should be maintained. Increase in the intake of fluids may cause undesirable dilution of ketogenic products.

5. If the infection is in the upper part of the urinary tract, treatment must be continued for a longer time than if the infection is in the bladder.

6. The ketogenic diet tends to entail constipation and gastro-intestinal upsets, but a dietitian can forestall these effects.

7. Escherichia coli responds to this type of treatment more readily than organisms of the genus Pseudomonas or than Aerobacter aerogenes. These organisms apparently continue to grow at an acidity which entirely inhibits the growth of Escherichia coli. However, in cases in which the organisms present were gram-negative bacilli other than Escherichia coli, with the exception of case 15, the symptoms were greatly improved, the haziness of the urine disappeared, and only on culture of the urine was it possible to find organisms.

8. When patients are given the ketogenic diet, the appearance of acetone bodies in the urine and increase in the acidity of the urine would be expected. Nevertheless, in some cases such bodies are not found and acidity is not increased. Case 15 is in point. The patient was given the ketogenic diet without success and then was given large doses of ammonium nitrate and ammonium chloride, which also would tend to lower the $p_H$ of the urine. However, the reduction in $p_H$ actually accomplished was only 0.3.

9. The effect of the ketogenic regimen does not seem to be solely the result of reduction of the $p_H$ of the

*Treatment of Cases*

| Case (All Male) | Age | Duration of Illness Before Ketogenic Treatment | Initial Condition of Upper Part of Urinary Tract | Organisms in Culture of Urine | Days of Diet Until No Growth on Culture | $p_H$ of Urine at Start of Ketogenic Treatment | Lowest $p_H$ of Urine (Under Treatment) | Culture of Urine, Last Examination* |
|---|---|---|---|---|---|---|---|---|
| 1 | 35 | 3 years | Not known | Escherichia coli and Aerobacter aerogenes | 11 | 6.8 | 5.0 | No growth |
| 2 | 56 | 2 months | Negative | Escherichia coli | 7 | 6.9 | 5.7 | No growth |
| 3 | 54 | 18 months | Pyelonephritis | Escherichia coli | 12 | 6.3 | 4.6 | No growth |

# SUICIDE

## POSSIBILITIES OF PREVENTION BY EARLY RECOGNITION OF SOME DANGER SIGNALS

RUTH E. FAIRBANK, M.D.
Associate in Psychiatry, Johns Hopkins Hospital
BALTIMORE

The cunning of the suicidal impulse is so baffling and the result such a deplorable frustration of medical effort that the dangers cannot be too often emphasized nor the importance of a continued search for a better understanding of the underlying factors overstressed. At the suggestion of Dr. Adolf Meyer, a careful study of 100 cases of suicidal attempts was made for the medical and nursing staff of the Henry Phipps Psychiatric Clinic, of which some of the deductions may be of wider interest.

Historically, it has been found that the attitude of the individual and of the public toward suicide has undergone many changes throughout the past centuries. Among the Greeks and Romans[1] it was an outgrowth of individualism and was not associated with shame but was rather considered a matter of honor, a custom present today in Japan, where hara-kiri, or honorable suicide, still exists. During the middle ages suicide became infrequent, but with the reformation and the recognition of individual freedom it increased. The reaction to this exacerbation brought about efforts at control by refusal of funeral rites or by legal punishment of the unsuccessful. Many of these laws have been repealed in this country,[2] and attempts at self-destruction are treated with some commiseration. What is more important, a study of the cases and more interest in help and prevention by attempts to understand and to determine better ways of dealing with the individual and with the group attitude has slowly been developing among the medical profession.

A large amount of literature has gradually accumulated on the question of suicide, written more from the standpoint of sociology,[3] pathology[4] and psychoanalysis,[5] with relatively few articles of practical help concerning the prevention.[6] The intentional termination of life is by no means always due to mental disorder;[7] if one considers the patients seen in an accident dispensary,[8] one has the general impression that a number of attempts come as impulsive or ruminative despair and spite reactions and are not the result of a mental illness so much as a maladaptation to the situations of life, reacted to in a rather childish, impulsive way.

The present study of forty-seven women and fifty-three men is principally concerned with attempts in which the physician, the nurses and the friends of the "suicide" have reason to feel that with better knowledge and greater care and attention it might have been possible to prevent what is usually a serious trauma to the unsuccessful and a deplorable event to everybody. While practical help may perhaps be obtained from the unheeded warnings and from the failures in judgment that seem to stare one in the face in retrospect, a brief analysis will first be presented of the facts given by the case histories concerning the types of mental reactions in which this urge occurs, the apparent motives, what the patients talked about, the personality, the heredity and the variety of suicidal methods of which one should be aware.

### MENTAL REACTIONS

As reported over a period of many years by various writers, suicide has occurred in almost every type of mental illness, but it is most frequently associated with depression.[9] In 100 cases studied, 73 presented outspoken depressions and 17 of the 24 paranoid and schizophrenic cases showed at least depressive waves; there were, moreover, 5 patients with psychopathic personalities, 2 cases of dementia paralytica and 1 case each of epilepsy, chronic invalidism and recurrent manic excitement. The depressions included agitated, hypochondriacal, paranoid, unreality, obsessive and manic-depressive types.

### MOTIVES

In a study of 500 cases by Mühl,[10] there was always a feeling of failure or frustration. In analyzing the life situations of our group, this is often apparent: it may be a failure at self-control, or grieving over a loss, or any of the variety of frustrated ambitions which one finds in the study of a personality. While certain writers give incest, onanism, wishing for the death of another individual and escape in order to return to the prenatal state as analytic interpretations, these motives have not been apparent in our material. We see rather the wish to escape from mental suffering, from fears or difficult family situations and disappointments, and whether this can be interpreted as the freudian death-wish depends on the trend of one's analytic interest. "Hopelessness" and "despair" were spoken of in about half of the case histories in which motives were stated. It is interesting to note the relative frequency of the statement of a fear or sometimes the conviction that a patient has of "losing his mind" or "going crazy." This topic of a fear of insanity was found to occur more frequently in depression, but it also occurred in the schizophrenic, the constitutional psychopathic and the paranoid reactions. The fear of insanity seemed in a few cases to be related to a fear of the inheritance of

mental illness and only infrequently was it associated with conflict over masturbation. In the depressions it no doubt is associated with the difficulty in thinking, which is a frequent complaint in this reaction and taken by the patient as a sign of deterioration and degeneracy. Spite seemed to be a possible motive in a few cases. Other patients apparently chose death as an escape from delusional persecutions such as a fear of being castrated or of being poisoned, killed or tortured. Two patients commited suicide to avoid actual situations which they found it difficult to face, while another, who almost succeeded in decapitating herself, gave as her reason for the desperate attempt the feeling she had of emptiness and inability to discuss her problems with us, a procedure she thought we would insist on, and the conviction that this was evidence of a fundamental lack in her. One man who is still miraculously alive tried for months to mutilate himself because he felt that the physicians wanted him to atone for feelings of guilt over infidelity, and in a later depression he tried to kill himself by jumping from a moving train "for the sake of his family," showing the false sacrificial basis of some suicidal motives.

The main value in a discussion of the actual content lies in the hope that such phrases as "I am an empty shell," "I'm guilty," "I am afraid of going crazy," "there is no hope for me" and "it's no use going on" may become danger signals and give warning that special watchfulness is indicated.

### PERSONALITY

The only outstanding characteristic in common found in a study of the personality traits in this group is the so-called "rigid"[11] or "stubborn" personality, which was noted in about one third of the cases. Probably rigidity or the lack of plasticity in the make-up could be considered as one of the factors of determination, apart from mere impulsive panic, which influence a patient to suicide.

### HEREDITY

A family history of suicide was found in only a few cases, but a history of depression, of psychotic relatives or of alcoholism was more frequent. Whether the tendency to self-destruction is inherited or not, the knowledge of suicides in the family undoubtedly has a suggestive influence.

### METHODS

The methods of self-destruction are of interest as to group habits, to personal tendencies and to preoccupations, and they give information regarding the variety of things from which it is necessary to protect the potential suicide. This varies with the opportunities at hand in the hospital and the somewhat wider possibilities on the outside. Regarding protection, a restriction of the sale of firearms and of poisons such as mercuric chloride, carbolic acid, iodine and potassium cyanide, as well as such sedatives as veronal (barbital), which can be obtained without prescription in Maryland, might help to reduce the number of suicides somewhat where law observance can be generally expected; but there are always other possibilities such as hanging, drowning, inhaling gas, jumping from heights, impulsively plunging down stairs or against a wall, jumping from a moving train, cutting the throat or wrists with a razor blade or a piece of broken glass and jabbing a sharp instrument into the heart. The type of method chosen is also determined by the prevailing social custom or "style," as indicated in the frequent newspaper reports of gunshot wounds and gas poisoning at present, or the cup of hemlock in ancient times. We did not find any specific relation between the type of mental reaction and the method chosen, although in the schizophrenic and paranoid cases the more bizarre means were apt to be chosen.

### WARNINGS

The topic of warnings may perhaps raise the hope that here is something on which dependence may be placed as a help in the prevention of suicide. It will take a further study of control groups to make any "warning" in any way specific of this danger. However, our records show that more than one third of the patients gave a very definite indication of danger by having made a previous attempt at self-destruction. An individual who has once taken this step seems rather more determined to "get away with it," and one finds such statements as "I'll make a better job of it next time." Besides these cases, approximately another third suggested their intentions by talking about it. It has sometimes been said that one need not fear suicide if a patient talks of it, as he "takes it out in talking," but this has not been our experience. This does not mean that in every case record one finds repeated expressions of wanting to die, of threatening suicide or of asking and looking for means with which to do it, for in some records one finds only isolated statements of this sort in the nurses' notes. In many cases, on the other hand, practically the entire talk and activity seem to be concerned with suicidal thoughts or threats. There were fourteen patients who gave no indication of their preoccupation or intention other than the fact that they were depressed or very tense. In contrast to these were six cases in which the suicidal impulse came out of a clear sky, and there were four cases in which we learned only after the disaster that something could have been done had the relatives or friends been more prompt in confiding to us their suspicions. Other symptoms that might be considered as possible danger signs because they immediately preceded the suicidal impulse are such behavior as pacing the floor when the patient has shown no previous agitation, attempting to pull away from nurses or attendants while being accompanied to another part of the building, or an overeagerness to join in some activity outside the ward in an agitated patient who has shown no previous interest. Also the period of convalescence is precarious, as the improvement in symptoms may bring a false optimism and relatively often an unanticipated suicidal attempt.

It is instructive to note that one sometimes finds that patients more or less consciously make an effort to protect themselves against their own morbid impulses. For instance, one of the patients, while in a general hospital, asked the nurse to hide his razor as he "couldn't see it without wanting to cut his throat," which he actually succeeded in doing later when he saw a knife in the office of a physician whom he consulted. Another patient, obsessed with the idea of suicide, refused to go to the carpenter shop "because he couldn't trust himself with anything sharp." Another came to the clinic begging to be taken in because he was afraid he would kill himself. The fact that so many of our patients talked of suicide suggests a half-conscious reaching out for protection.

On the other hand, we often deal with the sly, secretive patient who hides pieces of glass or conceals razor blades in his clothing. Recently a patient was found to have a revolver with him which he said he always carried to protect himself when driving in the country, but he later confessed that he had bought it with the intention of killing himself if we did not find anything wrong with him and did not take him into the clinic, which we fortunately did. A patient entered the hospital with veronal sewed in the lining of her coat which was not discovered until after she had taken enough to produce a stupor for several hours; she later killed herself elsewhere by thrusting scissors into her heart while the nurse prepared her bath. Another woman concealed veronal in the lining of her hat; other patients have procured razors, veronal or revolvers while out on parole and secreted them in their clothes. The duty of searching diligently for such objects is not a pleasant one, but it is very necessary with suicidal patients.

### SPECIAL PROBLEMS

This brings us to the topic which is perhaps the most difficult but the most instructive if we are to profit by experience, that of the consideration of medical and nursing responsibility and the situations in which judgment plays a rôle. We perhaps need not be as concerned over the patients who were discharged to other hospitals or taken home against our urgent advice, as with the patients who were apparently discharged with our consent, several of whom killed themselves within a period ranging from a few days to five months after leaving the hospital. This is suggestive of a premature discharge rather than of a recurrence of symptoms. No doubt many patients have been allowed to leave the hospital with some misgivings on our part who have made an uneventful recovery, and others have been taken against our advice and have done equally well, but it is important to emphasize the need of a recorded discussion of the risks involved with some responsible member of the family in every discharged case in which suicide has been a problem or even a possibility.

One of the questions that frequently come up for discussion in the hospital is whether or not a patient should be placed on "suicidal observation" and when such orders can safely be discontinued. This order may be either not given in time or prematurely canceled in order to spare the feelings of the patient or to give m[illegible] by permitting greater freedom. [illegible]icide should be such an inherent part of the atmosphere that it should be unnecessary to make special orders for it; nevertheless it seems almost impossible to have a ward free from such potentialities without making the patients in general suffer from a deprivation of interests. Hence there is a need of special technical "suicidal observation," even if it has disadvantages. That this order may have a suggestive influence is also true. Many patients have complained that they had never thought of the various possibilities until their attention was called to doors being locked, windows being guarded, bureau scarfs being removed, nail files and hair pins and scissors being collected; other patients who are somewhat paranoid misinterpret the constant watching. Nevertheless, experience shows that almost all suicidal attempts occur when the patient is left alone, and we should be able to offer protection by obviating this situation. Orders that doors should be allowed to be closed on the latch or for patients who have been depressed to be given parole should be matters of concern, as is the order for an agitated patient to be given permission to be taken for special therapy to other parts of the building. However, the desire to help the patient sleep who is oversensitive to noises, and the effort to encourage the individual apparently recovering from depression to try himself out, or to keep the agitated patient from chafing unnecessarily against restrictions are all understandable exceptions to the usual routine of suicidal protection and not without therapeutic justification. Experience would nevertheless warn us not to take these risks unless there is good rapport with the patient or an understanding with the family regarding the sharing of responsibility.

This question of responsibility in cases of suicide becomes at times an unwelcome burden, when legal advantage is sought by survivors of the unhappy patient. To allow the idea to prevail that hospitals, nurses or physicians should be liable for damage, unless neglect is obvious, may do a great deal of harm. Responsibility is hardly ever absolute or one-sided. The cunning and persistence of some of the attempts would baffle almost any measure one might think of. There must be a definite latitude for judgment and not every lapse should be judged indiscriminately. The scope of therapeutic activity prescribed in these cases must depend to a large extent on the rapport with the patient and the willingness of the family to share the responsibility when risks are involved. Measures of protection, however relative, will nevertheless be all the more important.

The following cases are given in brief summary to illustrate some of the special hazards and the somewhat unusual means of succeeding, which are not easily anticipated.

Case 1 shows the power of suggestion and the harmful influence newspaper reports of suicide can have, as well as the danger of having firearms available at home:

Case 1.—A married man, aged 27, came to the general hospital because of hypochondriacal fears of some months' duration and of more recent depression and "lack of concentration" after hearing of the suicide of a friend who had cut his throat with a razor. He worried over thoughts of taking his own life and, when left alone by his nurse, impulsively dived out of the second story window, causing a hemothorax which gradually cleared up. He was transferred to the Phipps Psychiatric Clinic immediately following this impulsive attempt. During the next few months he expressed many vague worries and fears: "I'll be punished for what I have done" (showing guilt over masturbation), or "I think my mind must be affected" (the fear of insanity). With these fears he also had waves of depression but was beginning to show an interest in activities again when he read in the newspaper that a patient who had been discharged home shortly before and with whom he had talked a good deal about farming had shot himself. This came on top of a little flurry of discouragement over having heard an orderly talk of taking a patient to the city hospital "as he was incurable." After reading of the suicide, the patient could not seem to throw off the fear that he would kill himself. He spoke of "not being willing to trust himself with a gun" and did not go to a carpenter shop lest he "cut his throat"—an effort to protect himself. He was obviously filled with a fear of suicide that amounted almost to fascination. He brooded over his symptoms and said "my mind is not functioning," "I'm hopeless of ever getting it right," and spoke of the family history of insanity. The patient was allowed to go to the pool room one evening and managed to avoid the nurses and escape and get home without attracting immediate attention and had shot himself before the physicians who followed him home could reach him. Naturally, this patient was unusually suggestible, but had the incident of the newspaper notice occurred when he was not in a depressed wave, he might not have acted on the suggestion.

Case 2 illustrates the dangers of stairs and walls. This case is also chosen to show that a depressed patient who develops delusions of persecution can be very desperately driven to suicide.

Case 2.—A single man, aged 49, complained of worry over past sex affairs and responded to efforts to discuss this topic with him by a fear that what he had said would be used against him. He regretted having told so much of his personal affairs, became suspicious that the patients were at the clinic to get data on him and that the government had set traps for him and would punish him. The next step was a belief that his food had been "doped" in order to make him talk and that a dictaphone had been used to record what he had said. He was recognized as suicidal and the extra watching required by suicidal observation only made him suspicious that he was being watched to detect masturbation, and he then developed a fear that he would be castrated. He said that he was "crazy" and that there was "no hope" for him now, and he felt he had in some way disgraced the whole institution. It was impossible to reassure him.

In a state of such widespread misinterpretation it would no doubt have been wiser to restrict the patient's activities to the ward, but in an effort to stimulate his interest in work he was taken to the occupation rooms and while there talked constantly to himself, which showed his preoccupation. On the way back to the ward he broke away from the nurse and attendant who were accompanying him and plunged head first down the marble stairs, fracturing his neck.

One cannot easily hope to prevent a strong patient from suddenly pulling away from those accompanying him. While in such a panic, occupation should be brought to the ward and the risk of impulsiveness thereby somewhat reduced. Unfortunately, even within the ward one patient has been successful in breaking his neck by butting his head against the wall.

The dangers of the transportation of a depressed patient need to be emphasized. Case 3 is presented to show the type of precaution needed in cooperation with the railroads:

Case 3.—A single woman, aged 57, who became suicidal and self-accusatory following the death of her mother and the breaking up of her home, was on the train being transferred from the clinic to another institution when she managed to escape from her nurse and a relative long enough to lock herself in the toilet room, and she was able to get the window up and jump from the moving train before the porter could be reached and the door opened.

Another patient, mentioned previously in the discussion of "motives," got out of the window of his berth while left alone a minute, but escaped death almost miraculously, sustaining only a few bruises.

This gives a few of the situations of which one needs to be aware in caring for the potential suicide.

## SUMMARY

The only possible cure of suicide is prevention. What are some of the guide-posts one can use?

1. Most suicides occur in patients who are depressed, but suicide is also relatively frequent in schizophrenic and paranoid patients, especially those whose conversation reveals depression.
2. Disappointment over some situation which seems unmodifiable to the rigid individual is perhaps the most common motive in suicide. A common feature in our cases is the talk of hopelessness, of wanting to die, of a fear of "going crazy"; such expressions as "a feeling of emptiness," of "guilt," or the special preoccupation with various delusions of persecution and with autistic fantasy.
3. The "rigid personality" is present in about one third of the cases and shows the need of careful watching.
4. A family history of suicide is apt to reduce the resistance.
5. Methods show the things from which patients need to be protected. In the hospital the impulsive plungers are especially difficult to take care of. On the outside, suicides from gas, gun-shot wounds and drowning are frequent.
6. Warnings are to be found in previous attempts and the frequent talk of suicide. Some patients, however, give no warning; others apparently try to protect themselves, while a third group conceal the means of suicide.
7. Special problems involve such questions as when to put a patient on suicidal observation and when to take him off, and how much risk to take in order to encourage an interest in occupation or to avoid unnecessary chafing against restrictions. The methods to be adopted must in the end rest with the personnel in charge, depending to a large extent on the rapport with the patient and the willingness of the family to share the responsibility which such a risk involves.
8. Finally, regarding prevention, I would suggest the restriction of the loose handling of firearms, poisons and sedatives, if possible, and would urge the cultivation of a sensitiveness to the aforementioned symptoms, warnings and mistakes. It is necessary to realize that a suicidal patient must never be left alone.

Johns Hopkins Hospital.

# POLYCYTHEMIA VERA

## REPORT OF CASE TREATED WITH PHENYLHYDRAZINE HYDROCHLORIDE OVER PERIOD OF SEVEN AND ONE-HALF YEARS

CLAIR L. STEALY, M.D.
SAN DIEGO, CALIF.

In April, 1928, I[1] reported a case of polycythemia vera which had been under observation and treatment with phenylhydrazine hydrochloride for three and one-half years and drew the following tentative conclusions from my experience with this case:

1. The erythrocyte count may be kept near normal limits by the periodic administration of 2.1 Gm. of phenylhydrazine hydrochloride divided into daily doses of 0.1 Gm. each. The drug may then be safely discontinued for intervals of one and one-half months.
2. No apparent tolerance to the drug was acquired.
3. The increase in leukocytes may possibly be used as an index to the administration of the drug.
4. No apparent deleterious effect on the liver was observed.

Treatment of this patient for the first six months consisted of the removal of three infected teeth, the administration of splenic extract and benzene by mouth, and roentgen therapy to the long bones. Under this treatment the patient noted some subjective improvement and there was some diminution in the size of the spleen, but there was very little change in the red blood cell count. Medication was then changed to phenylhydrazine hydrochloride by mouth and for the past seven and one half years the patient has been under constant observation and treatment with this drug. I feel that sufficient time has now elapsed to allow me to draw some more or less definite conclusions in regard to these four points under consideration and to suggest some possible explanations for the apparent discrepan-

---

From the Rees-Stealy Clinic.

[1] Stealy, C. L.: Polycythemia Vera, J. A. M. A. 90: 1287 (April 21) 1928.

cies brought out by other workers in the results obtained in the treatment of polycythemia with phenylhydrazine.

The observations of the physical examination at this time are not essentially different from those of seven and one-half years ago. The patient states that subjectively she is feeling very well and recently she has been doing rather heavy work connected with fitting up an apartment house. The skin is of a moderately dusky color and the mucous membranes are normal in color when the red cell count is down. The chest and heart manifestations are normal. The liver edge is slightly palpable on deep breathing and the spleen extends to the midline and almost to the crest of the ileum. The spleen is now smooth, however, and no tenderness can be elicited, whereas at the time of my first examination it had a sharp edge and notch and was exquisitely tender. Pelvic examination revealed a normal condition.

1. *Dosage.*—Based on the constant results observed in the treatment of this case, on my experience with two other cases and on the observations of others, especially Giffin [2] and Altnow and Carey,[3] it is my belief that the necessary dosage will vary with the individual case but that, once it has been established, the patient will respond consistently within normal variations to the same dosage. The dosage may vary with different individuals.

2. *Tolerance.*—My experience with this case [1] has disclosed no evidence to show that a patient will develop a tolerance to the drug and require a constantly increasing dosage. It would appear that the patient at times acquired a temporary tolerance to the drug, but in subsequent periods her reaction to the original dosage was the same as during the first periods of medication. This indicates, I believe, that some unknown factor may produce a temporary tolerance, and it may be that instances of increased tolerance to the drug reported in the literature [4] were obtained during such temporary periods of increased tolerance and that, had further observation of the case been possible, the previous reaction to the drug would have been obtained.

3. *Leukocytosis as an Index to Treatment.*—The rise in the leukocyte count precedes the fall of the red cell count in most periods of medication, and the rise of the white cell count varies in different periods of medication, but I do not feel that the white cell count can be used as an index to treatment. At the time of the highest rise of the white cell count, during the period from Nov. 20 to 28, 1930, its use as an indicator for the discontinuance of the drug would have been quite correct, for there was a decided drop in the red cell count. During the period of medication between June 13 and July 1, 1929, however, when the white cell count reached its second highest point, the red cell count varied but little. During this period, therefore, a discontinuance of the drug although seemingly indicated by the extreme leukocytosis was in reality not justified since there had been but little decrease in the red cell count. An explanation of this variability may be found in Allen's [5] experimental work. He reports that the phenylhydrazine seems at times to act directly on the hematopoietic system and at other times directly on the red blood cells—hemolysis; the increase in the white cell count may be due partly to the breaking down of the red cells and partly to the stimulation of the hematopoietic system. This variability leads me to conclude that the rise in the leukocyte count cannot be used as an indicator for the discontinuance of the drug.

4. *Development of Cirrhosis of the Liver.*—After seven and one-half years of treatment there is no physical evidence of a cirrhosis of the liver in the case under discussion. Nov. 18, 1930, six years after treatment with phenylhydrazine was started, the liver function test in which bromosulphalein was used showed no retention of the dye. It seems probable that any damage to the liver resulting from the use of the drug would have begun to make itself apparent over this period.

Table 1.—*Basal Metabolic Readings*

| Date | | Reading |
|---|---|---|
| 6/10/29 | Before starting phenylhydrazine........... | Plus 19 |
| 6/17/29 | While taking phenylhydrazine............. | Plus 31 |
| 6/24/29 | While taking phenylhydrazine............. | Plus 18 |
| 7/ 1/29 | After stopping phenylhydrazine........... | Plus 25 |

The differential leukocyte counts have revealed a uniformly high neutrophil and low lymphocyte percentage. This is in accord with the observations of Altnow and Carey [3] and also of Allen and Giffin.[5]

That the basal metabolic rate is increased in polycythemia has already been noted, especially by Bliss [6] and by Minot and Buckman.[7] My readings varied, from plus 19 to plus 31. A reading of plus 19 was obtained, June 10, 1929, before a period of medication was started; readings of plus 31 and plus 18 on June 17 and 24, respectively, while the drug was being administered, and plus 25 on July 1 after medication was discontinued. From these variations it would seem that, although the readings are above normal, such readings are a result of the disease and not an effect of the phenylhydrazine therapy.

The urea, nitrogen and creatinine determinations apparently do not vary from normal. It is also to be noted that there is no variation either at the height of destruction of red cells or during the rest periods.

Table 2.—*Blood Chemistry Determinations*

| Date | | Urea Nitrogen, Mg. per 100 Cc. | Creatinine, 100 Mg. per 100 Cc. |
|---|---|---|---|
| 11/14/24 | While taking phenylhydrazine.. | 14.5 | 2.04 |
| 12/27/27 | While taking phenylhydrazine.. | 16.2 | 2.25 |
| 9/24/28 | Not taking phenylhydrazine.... | 17.0 | 2.2 |
| 11/17/30 | Not taking phenylhydrazine.... | 13.3 | 1.8 |

The carbon dioxide combining power is apparently within normal limits, and there is no variation either during treatment or during rest periods.

During the resting stage the icterus index reading is normal or slightly above normal, but during the period of treatment it increases markedly and the patient develops a clinical jaundice. The serum bilirubin during the resting periods is apparently slightly higher than normal, in my case 1.65 mg. per hundred cubic centimeters (normal, from 0.1 to 0.3 mg.) but during the height of treatment the icterus index rose to 35 (normal, from 4 to 6) and the serum bilirubin to 4.5 mg. per hundred cubic centimeters. An immediate direct van den Bergh reaction was not obtained at any examination. In each instance the reaction was delayed, indicating a hemolytic jaundice.

[5] Giffin, H. Z., and Allen, E. V.: Experiments with Phenylhydrazine: I. Studies on the Blood, Ann. Int. Med. **1**: 655-656 (March) 1928.

[6] Bliss, T. L.: Basal Metabolism in Polycythemia Vera, Ann. Int. Med. **2**: 1155-1161 (May) 1929.

[7] Minot, G. R., and Buckman, T. E.: Erythremia (Polycythemia Rubra Vera); Development of Anemia; Relation to Leukemia; Consideration of Basal Metabolism; Blood Formation and Destruction and Fragility of Red Cells, Am. J. M. Sc. **166**: 469-489 (Oct.) 1923.

Kidney tests have disclosed no apparent indication of kidney damage. The intravenous phenolsulphonphthalein test, Sept. 11, 1928, showed the appearance of 66 per cent of the dye in the first hour and 22 per cent in the second hour, a total of 88 per cent; June 22, 1929, the test showed 77 per cent of the dye in the first hour and 16 per cent in the second, a total of 93 per cent; in November, 1930, 35 per cent of the dye appeared in the first thirty minutes, 20 per cent in the second thirty minutes and 7.5 per cent in the second hour, making a total of 62.4 per cent. This last reading is somewhat lower than the previous determinations but is still within normal limits.

Table 3.—*Icterus Index Readings*

| Date | Icterus Index, Mg. per 100 Cc. (Normal, 4-6) | Serum Bilirubin, Mg. per 100 Cc. (Normal, 0.1-0.3) | Reaction |
|---|---|---|---|
| 11/20/30...... | 12.5 | 1 65 | Delayed direct reaction |
| 11/21/30...... | 15 3 | .. . | Delayed direct reaction |
| 11/22/30...... | 19.0 | . . . | Delayed direct reaction |
| 11/24/30...... | 20.6 | .... | Delayed direct reaction |
| 11/25/30...... | 25.0 | 2.9 | Delayed direct reaction |
| 11/26/30...... | 25 0 | .. . | Delayed direct reaction |
| 11/28/30...... | 33.0 | 4.5 | Delayed direct reaction |

My observation of this patient over a period of years has suggested to me that some of the discrepancies as to results of treatment with phenylhydrazine hydrochloride found in the literature may be explained by the fact that single determinations were made on patients observed for short periods. Observations in the same patient vary at different times and I believe that some unexplained physiologic condition of the patient at the time may account for the variation in reaction to the drug. It is my belief that, in all cases of polycythemia vera treated with phenylhydrazine, the patient must be individualized and treated as indicated by his individual reaction to the therapy.

Table 4.—*Phenolsulphonphthalein Kidney Function Test*

| Date | | 1st Hour, Per Cent | 2nd Hour, Per Cent | Total, Per Cent |
|---|---|---|---|---|
| 9/11/28 | Not taking phenylhydrazine.. | 66 | 22 | 88 |
| 6/26/29 | While taking phenylhydrazine | 77 | 16 | 93 |
| 11/10/30 | While taking phenylhydrazine | 55 | 7.5 | 62.5 |

## CONCLUSIONS

My experience with the use of phenylhydrazine hydrochloride in the treatment of a case of polycythemia vera over a period of seven and one-half years has seemed to me to show that:

1. Once the necessary dosage has been established for the individual patient, the patient will respond to that dosage consistently.
2. The patient does not acquire a tolerance to the drug necessitating increasing dosage.
3. The leukocyte count cannot be used as an index to treatment.
4. The drug does not produce any apparent deleterious effect on the liver or kidneys.

2001 Fourth Avenue.

# HEMORRHAGE INTO THE STROMA OF BOTH OVARIES

## A SEQUEL OF MITRAL STENOSIS

GEORGE J. RUKSTINAT, M.D.
CHICAGO

Hemorrhage into the ovarian stroma is an infrequent occurrence according to most authorities. Kaufmann[1] describes the lesion and states that the ovary may reach the size of a child's head and look like a blood-soaked sponge. Karsner[2] speaks of rupture of vessels in the margin of the corpus luteum producing diffuse hemorrhage throughout the ovary but adds that diffuse is much more unusual than focal hemorrhage. Aschoff[3] and Stengel and Fox[4] mention chronic heart disease and poisonings as etiologic factors in interstitial ovarian hemorrhage. "Hemorrhage into the ovary has been found at autopsy" constitutes the sole reference to this lesion *in the discussion of ovarian hemorrhage* in typhoid in one reference system.[5] Classifications of ovarian hemorrhage are numerous. That suggested by Novak[6] is theoretically sound and practical. His division into follicular hematomas which may be of either the graafian or the atretic follicle, corpus luteum and stromal hematomas represents a compromise between previous arrangements, some of which were simpler but not as specific, and others which were obviously too complex. He lists the causal agents in the various types of hemorrhage as local or general; includes under the former menstrual hyperemia and nonmenstrual factors as the active hyperemia of pelvic inflammations, the passive hyperemia caused by thrombosis, varix or torsion of the ovarian pedicle, and the vascular disturbances occasioned by primary or secondary neoplasms. Under the general causes are included blood dyscrasias, disorders of nutrition, hemophilia, infections such as typhoid, phosphorus poisoning, burns, and hyperemia of the abdominal organs.

This arrangement is adopted by Blair,[7] who adds, as a source of hemorrhage, endometrial ovarian implants as described by Sampson.[8] Forssner[9] was able to find evidence of ovarian pregnancy in two cases of ovarian hematoma and was of the opinion that serial section of all such hemorrhagic ovaries was necessary to rule out pregnancy. As a matter of fact, he was convinced of the existence of pregnancy even when there was no sign of its presence in serial sections. He emphasized that parts of ova may be shed with blood, become embedded in the clot and degenerate, or become infected, rendering identification difficult.

In the overwhelming majority of reported ovarian hemorrhages the bleeding is traceable to the follicular structures, including under this head the corpus luteum.

Novak [6] found that this prevailed in a study of eighty-five ovaries removed at operation. The hematomas were usually under 2 cm. in diameter, although he found one 6 cm. in diameter. In correlating the ovarian lesions with the stages of the menstrual cycle, he found follicular hemorrhages of the ovary and the perifollicular hyperemia which preceded them, occurring usually at or near the time of ovulation. Thus, such hemorrhages were seen between the seventh and sixteenth days of the cycle, while corpus luteum hemorrhages occurred later, from the sixteenth to the twenty-fifth day. Runge [10] was also impressed with the importance of menstrual cyclic changes in the 120 ovaries that he studied. He cut them in sections 5 mm. thick; he never found hemorrhages in the sclerotic small ovaries of women past the menopause, but in those of women in the childbearing period they were invariably present. There was no hemorrhage in fourteen ovaries from women past the menopause; hemorrhage emanating from follicular structures occurred 100 times and diffuse interstitial hemorrhage was noted 6 times. The sclerotic small ovaries had a poor vascular supply and no formation of follicles or corpora lutea. The localized hemorrhages were pinhead to almond sized, flat or irregular, and commonly surrounded by a small yellow band. At times the blood accumulations had a sickle form representing extravasation from the capillaries of the torn theca interna, which bulged the granulosa but did not break through into the follicle cavity. At times the blood was seen outside the shredded theca externa in the stroma, an extrafollicular hematoma.

*Diagnosis in Women from Whom Ovaries Were Removed*

| Diagnosis | Number of Cases |
|---|---|
| Chronic pelvic inflammatory disease | 62 |
| Myoma of the uterus | 20 |
| Carcinoma of the uterus | 14 |
| Ovarian cysts | 6 |
| Pyovarium | 5 |
| Metropathia hemorrhagica | 4 |
| Tubal pregnancy | 3 |
| Genital tuberculosis | 2 |
| Torsion of cyst pedicle | 1 |

The diagnoses in the women from whom these ovaries were removed are enlightening as shown in the accompanying table. Diffuse ovarian hemorrhage occurred in only the pyovaria and torsion of the cyst pedicle where it really is to be expected.

The occurrence of bleeding from a ruptured corpus luteum has also been traced to hyperemia induced by coitus.[11] Indulgence in such sports as rowing, tennis, and horseback riding may also lead to follicular rupture. It was also seen to follow straining at stool [12] and vomiting, as in an attack of appendicitis.[13] Hemorrhage from a corpus luteum with normal pregnancy is also recorded.[14]

Most observers seem to find no difficulty in locating the site of hemorrhage, but a few apparently have been unable to locate the source. So difficult did it appear to Cantoni [15] that he advocated special methods for preserving the blood in blocks and sections. Runge [10] encountered twenty-two ovarian hemorrhages in 1,000 laparotomies and was unable to classify twelve of them. Schumann [16] also admits inability to establish the origin of bleeding in some patients. Heidler [11] found numerous references to various etiologic factors in the production of interstitial ovarian hemorrhage but a woful lack of illustrative material. He reported interstitial hemorrhage in both ovaries of a woman, aged 22, who died of a recurrent verrucose aortic endocarditis. Streptococcus septicemia caused universal blood vessel injury in the form of metrorrhagia, bleeding gums, petechia of the skin and hemorrhages into the pleura, endocardium and stomach mucosa. The only reports he found at all similar to his were those of Olshausen,[17] whose patients had scurvy. Hemorrhages of a lesser extent have been observed in osteomalacia and even in newly born infants. Heidler [11] is skeptical concerning the occurrence of such hemorrhages as a result of anemia.

The ovaries that I had an opportunity to study were obtained after death from the body of a single woman, aged 38, who died of cardiac decompensation:

Following scarlet fever at the age of 12 years she had been an invalid because of marked dyspnea and edema of the lower extremities and on numerous occasions had such severe decompensation that death seemed inevitable. When admitted to the service of Dr. Joseph Jaros in the Frances E. Willard Hospital, she was suffering from labored, shallow respirations about 40 per minute; a pulse only occasionally perceptible, and a systolic murmur audible 6 inches away from the chest. For six months she had suffered from constant pain over the precordium, cough, general weakness, and an exaggeration of her dyspnea. A bluish tinge of the finger-tips and eyelids noted for two years also became more pronounced. For the last four weeks of this period she vomited at irregular periods but had no fever. In the hospital she was kept in a semi-Fowler position with knees elevated, received one-sixth grain (4 mg.) of morphine sulphate and two ampules of a digitalis preparation by injection and vomited eight times in fifty-seven hours. Her temperature was 97.2 F. rectally until six hours before death, when it rose to 99 F. The body was examined two hours after death.

The essential items of the anatomic diagnosis were: chronic indurative, deforming and acute thrombo-ulcerative mitral endocarditis; marked mitral stenosis; marked eccentric cardiac hypertrophy; petechiae of the skin; ecchymoses of the pleura and extensive interstitial hemorrhage of the ovaries; ascites; hydrothorax; anasarca; chronic passive hyperemia of the lungs, liver, spleen and kidneys; marked generalized arteriosclerosis.

At the postmortem examination the face and lips were cyanotic; there were five petechial hemorrhages of the skin of the front of the neck, moderate anasarca, and an ascites of about 1,000 cc. of clear straw-colored fluid. There were five subpleural ecchymoses of the left lung near the hilus, each about 1 cm. in diameter. There were about 200 cc. of clear yellow fluid in each pleural cavity, and this, with the space occupied by the huge heart, gave the impression that the lungs occupied about two thirds of their normal space.

The heart weighed 560 Gm. and measured 13.5 cm. vertically and 18.5 cm. transversely. The mitral orifice, viewed from the auricle, was from 15 to 17 mm. in diameter. The edges of the opening were hard, irregular, pitted, and coated with a thin layer of fibrin. The chordae tendineae were thick and so short that the front papillary muscle was attached almost the height of treatment the icterus index rose to 35 (normal, from 4 to 6) and the serum bilirubin to 4.5 mg. per hundred cubic centimeters. An immediate direct van den Bergh reaction was not obtained at any examination. In each instance the reaction was delayed, indicating a hemolytic jaundice.

Kidney tests have disclosed no apparent indication of kidney damage. The intravenous phenolsulphonphthalein test, Sept. 11, 1928, showed the appearance of 66 per cent of the dye in the first hour and 22 per cent in the second hour, a total of 88 per cent; June 22, 1929, the test showed 77 per cent of the dye in the first hour and 16 per cent in the second, a total of 93 per cent; in November, 1930, 35 per cent of the dye appeared in the first thirty minutes, 20 per cent in the second thirty minutes and 7.5 per cent in the second hour, making a total of 62.4 per cent. This last reading is somewhat lower than the previous determinations but is still within normal limits.

Table 3.—*Icterus Index Readings*

| Date | Icterus Index, Mg. per 100 Cc. (Normal, 4-6) | Serum Bilirubin, Mg. per 100 Cc. (Normal, 0.1-0.3) | Reaction |
|---|---|---|---|
| 11/20/30...... | 12.5 | 1.65 | Delayed direct reaction |
| 11/21/30...... | 15.3 | .... | Delayed direct reaction |
| 11/22/30...... | 19.0 | .... | Delayed direct reaction |
| 11/24/30...... | 20.6 | .... | Delayed direct reaction |
| 11/25/30...... | 25.0 | 2.9 | Delayed direct reaction |
| 11/26/30...... | 25.0 | .... | Delayed direct reaction |
| 11/28/30...... | 33.0 | 4.5 | Delayed direct reaction |

My observation of this patient over a period of years has suggested to me that some of the discrepancies as to results of treatment with phenylhydrazine hydrochloride found in the literature may be explained by the fact that single determinations were made on patients observed for short periods. Observations in the same patient vary at different times and I believe that some unexplained physiologic condition of the patient at the time may account for the variation in reaction to the drug. It is my belief that, in all cases of polycythemia vera treated with phenylhydrazine, the patient must be individualized and treated as indicated by his individual reaction to the therapy.

Table 4.—*Phenolsulphonphthalein Kidney Function Test*

| Date | | 1st Hour, Per Cent | 2nd Hour, Per Cent | Total, Per Cent |
|---|---|---|---|---|
| 9/11/28 | Not taking phenylhydrazine.. | 66 | 22 | 88 |
| 6/26/29 | While taking phenylhydrazine | 77 | 16 | 93 |
| 11/10/30 | While taking phenylhydrazine | 55 | 7.5 | 62.5 |

## CONCLUSIONS

My experience with the use of phenylhydrazine hydrochloride in the treatment of a case of polycythemia vera over a period of seven and one-half years has seemed to me to show that:

1. Once the necessary dosage has been established for the individual patient, the patient will respond to that dosage consistently.
2. The patient does not acquire a tolerance to the drug necessitating increasing dosage.
3. The leukocyte count cannot be used as an index to treatment.
4. The drug does not produce any apparent deleterious effect on the liver or kidneys.

# HEMORRHAGE INTO THE STROMA OF BOTH OVARIES

### A SEQUEL OF MITRAL STENOSIS

GEORGE J. RUKSTINAT, M.D.
CHICAGO

Hemorrhage into the ovarian stroma is an infrequent occurrence according to most authorities. Kaufmann[1] describes the lesion and states that the ovary may reach the size of a child's head and look like a blood-soaked sponge. Karsner[2] speaks of rupture of vessels in the margin of the corpus luteum producing diffuse hemorrhage throughout the ovary but adds that diffuse is much more unusual than focal hemorrhage. Aschoff[3] and Stengel and Fox[4] mention chronic heart disease and poisonings as etiologic factors in interstitial ovarian hemorrhage. "Hemorrhage into the ovary has been found at autopsy" constitutes the sole reference to this lesion in the discussion of ovarian hemorrhage in typhoid in one reference system.[5] Classifications of ovarian hemorrhage are numerous. That suggested by Novak[6] is theoretically sound and practical. His division into follicular hematomas which may be of either the graafian or the atretic follicle, corpus luteum and stromal hematomas represents a compromise between previous arrangements, some of which were simpler but not as specific, and others which were obviously too complex. He lists the causal agents in the various types of hemorrhage as local or general; includes under the former menstrual hyperemia and nonmenstrual factors as the active hyperemia of pelvic inflammations, the passive hyperemia caused by thrombosis, varix or torsion of the ovarian pedicle, and the vascular disturbances occasioned by primary or secondary neoplasms. Under the general causes are included blood dyscrasias, disorders of nutrition, hemophilia, infections such as typhoid, phosphorus poisoning, burns, and hyperemia of the abdominal organs.

This arrangement is adopted by Blair,[7] who adds, as a source of hemorrhage, endometrial ovarian implants as described by Sampson.[8] Forssner[9] was able to find evidence of ovarian pregnancy in two cases of ovarian hematoma and was of the opinion that serial section of all such hemorrhagic ovaries was necessary to rule out pregnancy. As a matter of fact, he was convinced of the existence of pregnancy even when there was no sign of its presence in serial sections. He emphasized that parts of ova may be shed with blood, become embedded in the clot and degenerate, or become infected, rendering identification difficult.

In the overwhelming majority of reported ovarian hemorrhages the bleeding is traceable to the follicular structures, including under this head the corpus luteum.

directly to the valve leaflet. Cultures of the heart's blood failed to produce a growth on blood agar.

The right lung weighed 650 Gm.; the left, 540 Gm. Both were boggy from edema and passive hyperemia and had an acute bullous emphysema along the ventral edge. The blood in all the pulmonary vessels examined was fluid, and, although a careful search was made for clots in both pulmonary artery and vein in the region of the ecchymoses in the left lung, none were found. There were calcified nodules of arrested tuberculosis in each upper lobe and in a tracheobronchial lymph gland.

The liver weighed 1,200 Gm. and grossly, as well as microscopically, bore the alterations of marked cyanotic atrophy. The other abdominal organs were the seat of a marked chronic passive hyperemia. Fatty and fibrous plaques typical of senile arteriosclerosis involved the lining of the arteries to the following extent: the coronary, renal, splenic, superior mesenteric, and pulmonary, 15 per cent; the thoracic part of the aorta, 50 per cent; and the abdominal part of the aorta, 75 per cent.

The ovaries were twice normal size, blotchy outside from subserous hemorrhages up to 5 mm. in diameter; alternating with tense gray-yellow cortex, and dripping with blood when cut across. The two ovaries were altered to the same extent and in a similar manner and, on many surfaces made by cutting, had a cortex from 1.5 mm. thick to the thickness of the serosa in the regions of great hemorrhage. The medulla resembled a bloody sponge with scattered fibrous septums.

The peritoneum of the pelvis and of the pelvic organs was dark red, with the finest radicles of the blood vessels visible. This was especially true of the fallopian tubes, which, near their fimbriated ends, were purple. The lining of the uterus was red with a slight pale yellow cast. The renal veins, common iliac and ovarian veins and inferior vena cava were hugely distended with fluid blood. Their lining was smooth and glistening. The fat about the kidneys and abdominal aorta was edematous.

In sections of both ovaries stained with hematoxylin and eosin and phosphotungstic acid hematoxylin, the prominent feature was the vast fresh hemorrhage. The red blood corpuscles were well preserved and all vessels, arteries, veins and capillaries were hugely distended. The media of the arteries was hyalinized as in the senile changes described by Sohma.[18] In all sections the walls of the arteries were intact, although frequently they were entirely surrounded by blood that saturated the stroma. Follicles in any stage of development were few but *corpora albicantia* were in evidence, often with multiple peripheral bloody impregnations continuous with the interstitial extravasations. In many regions nothing but blood was discernible in the central portions of the ovary, but toward the germinal regions columns of blood cells, one cell wide, alternated with a single layer of spindle-shaped cells from the shredded stroma. In the left ovary were two cysts, one in an old corpus luteum, the other in an atretic follicle, but there was no blood in the lumen of either, probably because their fluid contents withstood the pressure from without. The source of bleeding in both ovaries was the capillaries and smaller veins, in many of which actual rupture of the vessel was demonstrable. These vessels were usually some distance from follicles, and, indeed, were best seen when associated with small extravasations in an otherwise unchanged stroma. It was quite plain that bleeding from many places in the medullary part of each ovary had converted them into roughly oval masses with bloody projections, in shape somewhat like mulberries. These excrescences were easily seen grossly through the serosa. With this deep bleeding and its profound distention of the ovaries there were also numerous more or less discrete subserous capillary hemorrhages.

On the basis of the lack of evidences of disease of an inflammatory nature, coupled with the profound pelvic hyperemia, it was concluded that the ovarian hemorrhages occurred from stasis. This stasis in the pelvis was favored by the semi-Fowler position with the knees elevated and by the increased intra-abdominal pressure brought on by vomiting.

Clinically, the complications of mitral stenosis are legion and not infrequently perplexing. The prematurity and intensity of the pulmonary and hepatic disorders, the frequency of arrhythmic and embolic manifestations and the secondary production of insufficiency of the pulmonary valve serve as a starting point for the most varied disease pictures.[19] Dilatation of the left auricle may result in pressure on the recurrent laryngeal nerve and inequality of the pulse. The marked pulmonary surcharge is the basis for pulmonary hemorrhage of such frequency and volume that mitral stenosis is surpassed only by chronic bronchiectasis and phthisis as a cause of hemoptysis.[20] Functional incompetence of the pulmonary artery and its attendant murmur were described by Graham Steell, and Hall[21] asserts that it occurs in 4 per cent of all patients with mitral stenosis. Temporary regurgitation of the pulmonary valve may be produced in some people with healthy hearts simply by holding the breath.[22] The production of such an insufficiency with its protean manifestations of venous stasis seems inevitable in the final stages of mitral stenosis.

The hemorrhages into the ovaries that I examined resulted from stasis unaccompanied by infection or thrombosis. Such hemorrhages are unusual, as it is the stroma rather than the follicular apparatus that is involved.

645 South Central Avenue.

# THE OPHTHALMIC TEST FOR SENSITIVITY TO HORSE SERUM

LOUIE N. CLAIBORN, M.D.
NEW HAVEN, CONN.

Since diphtheria antitoxin came into general use in 1894, serum therapy and prophylaxis for this and many other bacterial diseases have been employed widely. Following this type of treatment, serum reactions of greater or less severity have been frequent. In many clinics today the intradermal test for sensitivity to horse serum is employed before serum is administered. The test, however, has never been completely satisfactory because of the inconstancy of the relationship of serum reaction to sensitivity, as determined by this method. There is a definite need for a simple test which will give a more reliable index of the degree of susceptibility of an individual to serum.

In 1928, Spicer[1] reported a series of 353 patients in whom the intradermal and ophthalmic tests for sensitivity to horse serum were contrasted. The results obtained by her suggested that the ophthalmic test is of considerably more value than the intradermal. It seemed of importance to us to compare these two tests in a series of patients and determine their relative value in relation to serum reactions.

In our series the patients tested were instances in which a prophylactic injection of tetanus antitoxin was indicated. They were for the most part ambulatory patients with minor injuries. Those receiving tetanus antitoxin were given 1,500 units intramuscularly. Two well known brands of tetanus antitoxin were used. The study extended over a considerable period of time, so that several different "lots" of serum were necessarily used.

[1] Spicer, Sophie: Ophthalmic Test for Horse Serum Sensitivity Contrasted with the Intradermal, J. Immunology **15**: 335-342 (July) 1928.

The usual intradermal test was employed. Approximately 0.05 cc. of tetanus antitoxin (horse serum) diluted 1:10 was injected into the skin on the anterior surface of the forearm. The opposite arm was used as a control, physiologic solution of sodium chloride being injected instead of serum. The tests were read after twenty minutes. The intradermal reaction usually appeared in from fifteen to twenty minutes and subsided in from twelve to twenty-four hours. The degree of positiveness was determined by the size of the wheal, presence or absence of pseudopods, and the redness surrounding the site of injection. For the ophthalmic test, one drop of tetanus antitoxin was instilled into the conjunctival sac of one eye. The test was read after fifteen minutes, the remaining eye serving as a control. The positive reactions varied from a slight injection of the conjunctival vessels to a marked conjunctival reddening. When the test was markedly positive, the patient usually complained of some burning and itching of the eye. The positive ophthalmic reactions usually appeared in from ten to fifteen minutes and subsided entirely in from one-half to two hours. No untoward ophthalmic reactions occurred.

When desensitization was necessary, the following procedure was carried out: Of antitoxin diluted 1:10 with physiologic solution of sodium chloride, 0.1 cc. was injected subcutaneously; at half hour intervals the following amounts were injected: 0.2 cc., 0.5 cc., 1 cc. and 2 cc. From this point, undiluted antitoxin was used. Two and one-half hours after the original injection 0.5 cc. was given, and one-half hour later 1.2 cc. This completed the total amount of serum, 2 cc. comprising 1,500 units of tetanus antitoxin. For slight reactions occurring during desensitization, the injection that caused the reaction was repeated after a thirty minute interval and the remaining injections were given according to schedule. For severe reactions epinephrine hydrochloride (0.3 cc. of 1:1,000 solution) was given intramuscularly.

In 465 patients both the intradermal and the ophthalmic tests were employed. The patients varied considerably in age, the youngest being 6 months and the oldest 72 years of age; 321 (69 per cent) were males and 144 (31 per cent) were females. In fifty-seven patients the antitoxin was diluted 1:1 for the ophthalmic tests. Since no untoward reactions occurred, undiluted antitoxin was used for the remaining 408 patients. The positive tests both intradermal and ophthalmic were recorded from + to +++, depending on the severity of the reactions. For the sake of simplicity, however, the results have been grouped into one series and positive tests recorded merely as positive without qualification.

Serum reactions were divided into three groups: immediate reactions, those occurring in less than twenty-four hours; accelerated reactions occurring after twenty-four hours but before the fifth day; and delayed, or ordinary serum reactions, those occurring from the fifth day on. In some instances patients developed more than one type of reaction. These were classified, however, under the group in which they first appeared.

## RESULTS

In all, 465 patients were tested: 26 (5.6 per cent) were positive to both tests; 99 (21.3 per cent) were positive to the intradermal but negative to the ophthalmic test, and 340 (73.1 per cent) were negative to both tests. All patients who had positive ophthalmic tests had also positive intradermal tests. Table 1 illustrates this.

TABLE 1.—*Results of Intradermal and Ophthalmic Tests in Four Hundred and Sixty-Five Patients*

| | Skin + Eye + | Skin + Eye — | Skin — Eye + | Skin — Eye — | Total |
|---|---|---|---|---|---|
| Number of patients........ | 26 | 99 | 0 | 340 | 465 |
| Per cent.................... | 5.6 | 21.3 | 0 | 73.1 | 100 |

There were 426 patients who received tetanus antitoxin: 4 (0.9 per cent) of these had immediate serum reactions. Of 204 patients observed for a period of ten days or more, 12 (5.9 per cent) had accelerated serum reactions and 33 (16.1 per cent) had delayed or ordinary serum reactions. These results grouped according to tests are shown in table 2.

TABLE 2.—*Relation of Tests for Sensitivity to Serum Reactions in Patients Receiving Tetanus Antitoxin*

| | Skin + Eye + | | Skin + Eye — | | Skin — Eye — | | Total | |
|---|---|---|---|---|---|---|---|---|
| | No. | % | No. | % | No. | % | No. | % |
| Patients receiving tetanus antitoxin | 17 | 4 | 79 | 18.5 | 330 | 77.4 | 426 | .... |
| Patients observed for ten days or more .............................. | 11 | 5.4 | 43 | 21 | 150 | 73.5 | 204 | 47.8 |
| Cases showing an immediate reaction (occurring in less than twenty-four hours) ........................ | 2 | 11.8 | 0 | 0 | 2 | 0.6 | 4 | 0.93 |
| Cases showing an accelerated reaction (occurring after twenty-four hours but before the fifth day)... | 3 | 27.2 | 3 | 7 | 6 | 4 | 12 | 5.9 |
| Cases showing delayed or ordinary serum reaction (occurring from the fifth day on).................. | 2 | 18.2 | 6 | 14 | 25 | 16.7 | 33 | 16.1 |
| Cases showing no reaction.......... | 4 | 36.4 | 34 | 79 | 117 | 78 | 155 | 76 |

Desensitization was done on twenty patients: two of these (10 per cent) had immediate serum reactions so severe that complete desensitization was not attempted. Twelve patients were observed for at least ten days; of these, three (25 per cent) had accelerated serum reactions, and two (16.6 per cent) had delayed serum reactions (table 3).

TABLE 3.—*Serum Reactions Following Desensitization Patients Grouped According to Tests*

| | Skin + Eye + | | Skin + Eye — | | Total | |
|---|---|---|---|---|---|---|
| | No. | % | No. | % | No. | % |
| Patients desensitized .............. | 13 | 65 | 7 | 35 | 20 | .... |
| Desensitized patients observed for ten days or more.................. | 9 | 75 | 3 | 25 | 12 | 60 |
| Cases showing an immediate reaction ................................ | 2 | 15.4 | 0 | 0 | 2 | 10 |
| Patients showing an accelerated reaction ........................... | 2 | 22.2 | 1 | 33.3 | 3 | 25 |
| Cases showing delayed or ordinary serum reaction .................. | 2 | 22.2 | 0 | 0 | 2 | 16.6 |
| Cases showing no reaction......... | 3 | 33.3 | 2 | 66.6 | 5 | 41.6 |

Eighty-one patients with positive tests, four positive to both and seventy-seven positive to intradermal but negative to ophthalmic tests, were given antitoxin without desensitization. The positive ophthalmic tests in this group were not strongly positive. No immediate reactions occurred. Forty-two patients were observed for at least ten days. Of these, three (7.1 per cent) had accelerated serum reactions, and six (14.3 per cent) had delayed serum reactions (table 4).

In a group of sixty-four patients who were known to have had horse serum previously, there was one (1.6 per cent) immediate serum reaction. Forty-four patients were observed for at least ten days; of these, seven (15.9 per cent) had accelerated serum reactions and eight (18.2 per cent) delayed serum reactions (table 5).

Table 4.—*Serum Reactions in Cases with Positive Tests Not Desensitized*

| | Skin + Eye + | | Skin + Eye − | | Total | |
|---|---|---|---|---|---|---|
| | No. | % | No. | % | No. | % |
| Patients with positive tests not desensitized | 4* | 5 | 77 | 95 | 81 | .... |
| Cases observed for ten days | 2 | 4.7 | 40 | 95.3 | 42 | 51.8 |
| Cases showing an immediate reaction | 0 | 0 | 0 | 0 | 0 | 0 |
| Cases showing an accelerated reaction | 1 | 50 | 2 | 5 | 3 | 7.1 |
| Cases showing delayed or ordinary serum reaction | 0 | 0 | 6 | 15 | 6 | 14.3 |
| Cases showing no reaction | 1 | 50 | 32 | 80 | 33 | 78.5 |

* All eye tests were weakly positive.

Of the 204 patients observed for a period of at least ten days there were in all 49 cases (24 per cent) of serum reaction. The severity of the reactions varied considerably. Twenty-four were mild, characterized by urticaria, fever and general malaise; twenty-three were moderately severe, presenting urticaria, fever, general malaise, vomiting and joint symptoms; two were severe (immediate) with urticaria, sneezing, coughing, respiratory difficulty, fever and vomiting.

Table 5.—*Relation of Sensitivity Tests to Serum Reactions in Patients Previously Injected with Horse Serum*

| | Skin + Eye + | | Skin + Eye − | | Skin − Eye − | | Total | |
|---|---|---|---|---|---|---|---|---|
| | No. | % | No. | % | No. | % | No. | % |
| Patients with history of having had serum previously | 9 | 14 | 21 | 32.8 | 34 | 53.1 | 64 | ... |
| Cases observed for ten days | 9 | 13.6 | 15 | 31 | 23 | 52.3 | 44 | 68.8 |
| Cases showing an immediate reaction | 1 | 11.1 | 0 | 0 | 0 | 0 | 1 | 1.6 |
| Cases showing an accelerated reaction | 2 | 33.3 | 2 | 13.3 | 3 | 13 | 7 | 15.9 |

| Cases showing no reaction | 1 | 16.6 | 11 | 73.3 | 16 | 69.6 | 28 | 63.6 |

Spicer[1] summarized the results of her series as follows:

> Of the 353 patients tested, 293 received antitoxin: 251 intramuscularly and 42 intravenously. There were eighty-two positive test reactions: thirteen ophthalmic and sixty-nine intradermal. All those who gave a positive ophthalmic test were also positive intradermally. Of the thirteen patients giving a positive ophthalmic test, seven were given antitoxin and each had serum reaction. Of the sixty-nine who were positive intradermally, fifty-four received antitoxin and of these twenty-four had serum reaction. Of the 271 negative patients, 232 received antitoxin. Of these, twenty-eight had serum reaction. In all there were fifty-nine cases of serum reaction. Fifty-three were mild, consisting of urticarial rash with pruritus and elevation of temperature from 1 to 3 degrees F., lasting from twenty-four to forty-eight hours. Six of the fifty-nine serum reactions were rather marked. . . .

## COMMENT

Four immediate reactions were observed. Two (18.8 per cent) severe reactions, occurring within a few minutes after the injection of a small amount of dilute serum, were seen in patients in whom both the ophthalmic and the intradermal tests were positive. The remaining two (0.6 per cent) were observed in patients in whom both tests were negative; the reactions, however, were mild and occurred several hours after all the serum had been given.

Accelerated reactions occurred in 27.2 per cent of the patients with both tests positive but in only 7 per cent of the patients with negative ophthalmic and positive intradermal tests, whereas they occurred in 4 per cent of those with both tests negative.

Delayed or ordinary serum reactions occurred about equally in the three groups: 18.2 per cent of the patients with both tests positive, 14 per cent of those with positive intradermal and negative ophthalmic tests, and 16.7 per cent of the cases with both tests negative had delayed serum reactions.

Desensitization in our small series of cases did not appreciably alter the percentage of serum reactions but, because of the slow administration, probably prevented more serious reactions.

In patients who had previously received horse serum the percentage of accelerated reactions was slightly higher than in those who gave no such history; the percentages of immediate and delayed reactions, however, were not noticeably changed.

All patients with positive ophthalmic tests also had positive intradermal tests. In general, the cases having positive ophthalmic tests had the most strongly positive intradermal tests. The results indicate that the intradermal test, although much more sensitive than the ophthalmic, is of less value for clinical use, whereas the ophthalmic test, although far from ideal, is of definitely greater value as a clinical index of susceptibility to serum reactions. The ophthalmic test is much simpler to do, since it involves no diluted serum or saline solution and obviates the need of two intradermal injections, which are bothersome and not a little painful to the patient.

## SUMMARY AND CONCLUSIONS

1. In 465 patients, both the ophthalmic and the intradermal tests were employed; 5.6 per cent were positive to both tests, and 21.3 per cent were positive to the intradermal test only.

2. All those who had positive ophthalmic tests also had positive intradermal tests.

3. Undiluted tetanus antitoxin (horse serum) may be safely used for the ophthalmic test.

4. The ophthalmic test is less sensitive but of more value as a clinical index of susceptibility to serum reactions than the intradermal test.

5. Four hundred and twenty-six patients received tetanus antitoxin; 204 were observed for at least ten days; 24 per cent of the latter presented serum reactions.

6. Desensitization did not appreciably alter the percentage of serum reactions.

7. In patients who had previously received horse serum, a slightly higher percentage of accelerated serum reactions was observed.

8. Delayed or ordinary serum reaction occurred in approximately the same percentage (from 14 to 18) of patients with both tests positive, those with the ophthalmic test negative and the intradermal test positive, and those with both tests negative.

# "MYXEDEMA HEART" WITHOUT EVIDENCE OF CARDIAC INSUFFICIENCY

## REPORT OF TWO CASES

DAVID AYMAN, M.D.
BOSTON

HAROLD ROSENBLUM, M.D.
SAN FRANCISCO

AND

MARK FALCON-LESSES, M.D.
BOSTON

In 1918, Zondek[1] reported that a specific cardiac abnormality was sometimes associated with myxedema, and he called it "myxedema heart." He observed four such cases in which the condition was characterized by enlargement of the heart, feeble cardiac action (observed with a fluoroscope), slow heart beat, low amplitude of the auricular (P) and final ventricular (T) waves in the electrocardiogram, and normal blood pressure. Furthermore, after the administration of thyroid the size of the heart diminished, its action became more vigorous, its rate increased, and the P and T waves of the electrocardiogram became more upright, while the blood pressure remained normal. He mentioned nothing about the presence of symptoms of cardiac insufficiency. Before Zondek, Eppinger,[2] in 1917, writing on the subject of edema, had described two cases of enlargement of the heart and cardiac insufficiency with marked edema, in which previous therapy with digitalis and diuretics had failed. The administration of thyroid produced a considerable decrease in size of the heart and caused the edema and cardiac symptoms to disappear. Eppinger believed that the effect of thyroid was purely that of a diuretic. Although no basal metabolic rates were reported and no mention was made of the presence of myxedema, it is possible that Eppinger's two cases were examples of "myxedema heart." Since Zondek's original description, others[3] have reported a total of twenty-two cases of "myxedema heart."

Table 1 summarizes the more significant features of the twenty-two reported cases. The average decrease in transverse diameter of the heart after thyroid administration was 3.3 cm., with a minimal decrease of 1.0 cm. and a maximal of 6.3 cm. Symptoms or signs of cardiac insufficiency were mentioned as present in fifteen of the twenty-two cases. Thus, thirteen patients complained of shortness of breath on exertion, seven patients had cyanosis, six had pitting edema, five had râles at one or both lung bases, and four had enlargement of the liver. These symptoms and signs of cardiac insufficiency disappeared after thyroid therapy. The most striking cases in the literature are those reported by Fahr[3] and Davis,[3] in which extreme cardiac enlargement and severe symptoms and signs of cardiac insufficiency were not relieved by digitalis and rest, were then relieved by thyroid, next recurred on the withdrawal of thyroid, and again disappeared on administration of thyroid.

Despite this evidence, some observers doubt the existence of the condition called "myxedema heart." Willius and Haines,[4] in a study of 162 case records of "high-grade myxedema," failed to find the cardiac changes described by Zondek in any instance, whereas Fahr found it in eight out of twelve cases of myxedema seen in his clinic.[5] Christian[6] reviewed thirty-two cases of well established myxedema and stated that he found no case showing the enormous cardiac enlargement described by Fahr.[3] Case,[7] in an analysis of fifty-eight cases of myxedema, found none corresponding to Zondek's description. Means, White and Krantz[3] found but one case of "myxedema heart" in forty-eight cases of myxedema. However, the observations of these authors indicating the rarity or nonexistence of the condition "myxedema heart" should be explained. Thus, only 32 per cent of the patients of Willius and Haines had electrocardiographic studies. Furthermore, Willius stated in a recent personal communication that although six-foot heart plates were made in the majority of their cases, only a few post-therapy studies were conducted. Finally, mention was not made by Christian, by Case or by Means, White and Krantz of the use of serial teleroentgenograms or electrocardiograms before or during treatment with thyroid.

We have observed two cases that illustrate the salient features of "myxedema heart." These cases are presented as further evidence that the condition occurs and that it may exist without cardiac insufficiency.

### REPORT OF CASES

Case 1.—A woman, aged 42, married, came to the medical clinic of the Boston Dispensary complaining chiefly of weakness. She said that her present illness had begun three years previously, following an attack of tonsillitis, laryngitis and influenza. Since then she had suffered from weakness, which had progressed to the point where the least exertion caused almost complete exhaustion. She had also noted marked sensitiveness to cold, coarse scanty hair, ribbed and brittle finger nails, coarse dry skin, puffiness of the eyelids, hands and ankles, poor memory, lessened acuity of hearing, drowsiness, marked constipation and irregular menorrhagia. She said that she had had three attacks of typhoid, at the ages of 5, 9 and 15 years, respectively. Spontaneous abortions had occurred four times. She had three living children. At no time had she noticed shortness of breath.

Physical examination disclosed that the patient was moderately obese and of medium height. She appeared drowsy, and she moved and talked slowly. Her skin was extremely dry and was of a yellowish pallor, especially on the face. Her fingers were cold. There was no cyanosis. There was no moisture in the axillae. The hair was very coarse; it was scanty in the axillae, and the lateral third of each eyebrow

was absent. There was slight puffiness of the lower eyelids. The tongue was clean and smooth, and its papillae were normal in number and size. The mucous membranes were of normal color. The thyroid gland was not palpable. The lungs had normal resonance; there were no râles. The heart was not enlarged to percussion. The sounds were distant, the rate was 60 a minute, and the rhythm was regular. Murmurs were not heard. The blood pressure was 120 systolic and 80 diastolic. The radial arteries felt soft. The edge of the liver was just palpable on inspiration and not tender. The spleen was not felt. A mass, which was not tender, was felt above the symphysis pubis just to the left of the median line. On vaginal examination this mass was found to be a symmetrically enlarged, freely movable, hard uterus about twice the normal size. The knee jerks were equal and active. There was no pitting edema of the extremities. The rest of the physical examination was negative.

* In cases 1 and 2, no thyroid had been given up to the first day of observation. The initial metabolism determinations were made before any medication was given. In case 2, 4 Gm. of iron and ammonium citrate in capsules was given daily from the first to the twenty-second day; 4 Gm. of the same medicine in 25 per cent solution from the twenty-third to the thirty-fifth day; 6 Gm. of the same solution from the thirty-sixth to the forty-ninth day, and 3 Gm. of reduced iron in capsules from the fiftieth to the seventy-first day.

† In case 1 measurements were made by orthodiagram and in case 2 by teleroentgenogram.

Further examination showed the following: The height was 160 cm. (63 inches) and the weight 76.7 Kg. (168 pounds). The Hinton, Wassermann and modified Kahn tests were negative. A specimen of urine showed a specific gravity of 1.023, no albumin, no sugar, and nothing abnormal in the sediment. The hemoglobin (Sahli) was 72 per cent, the erythrocytes numbered 3,700,000 and the leukocytes 6,525 per cubic millimeter. An examination of a blood smear showed slight achromia, slight variation in size and shape of the erythrocytes, and a normal differential count. The blood sedimentation rate was 3 mm. in one hour. The guaiac test for occult blood in the stool was negative. Gastric analysis on three occasions did not disclose any free hydrochloric acid either in the fasting contents or after an Ewald test meal; the total acidity on several occasions was 17 or less; gastric analysis after injection of 0.5 mg. of histamine intramuscularly disclosed free acidity of 5 (Ewald's scale) and a total acidity of 6. Roentgen studies of the gastro-intestinal tract were negative. An orthodiagram of the heart showed slight generalized enlargement producing a pear-shaped outline (table 2 and fig. 1 *A*). The measurements were: MR,[8] 4.4 cm.; ML, 8.7 cm.; TR, 13.1 cm.; internal diameter of the thorax, 25.7 cm. $\left(\frac{13.1}{25.7} = 51 \text{ per cent}\right)$; L, 13.8 cm.; B, 9.6 cm., and G. V., 7.3 cm. An electrocardiogram showed a heart rate of 50, the rhythm regular, minute P and T waves in lead 1 (0.3 and

---

[8] MR indicates distance from middle of thorax to outermost right border of heart; ML, distance from middle of thorax to outermost left border of heart; TR, MR + ML; L, length; B, breadth, and G.V., great vessels.

0.5 mm., respectively) and P and T waves absent in leads 2 and 3 (fig. 2). The P-R interval was 0.24 second. The basal metabolic rate was −53 per cent (by the Aub-Du Bois standard).

Diagnoses of myxedema, secondary anemia, and uterine fibromyoma were made. Following treatment with desiccated thyroid (table 2), the patient's basal metabolic rate became normal, and all the symptoms disappeared. Her anemia remained unimproved. Twenty-eight pounds (12.7 Kg.) in weight was lost during treatment. The heart decreased in size, and the electrocardiogram became normal. At the time of the last determination of the basal metabolic rate, following thyroid administration over a period of sixty-three days, the rate had risen to ±0 per cent. Thyroid medication was continued in appropriate amounts. An orthodiagraphic tracing made on the eighty-fifth day of treatment now showed the following measurements (fig. 1 *B*): MR, 3.8 cm.; ML, 8.3 cm.; TR, 12.1 cm.; internal diameter of the thorax, 25.9 cm. ($\frac{12.1}{25.9}$ = 46 per cent); L, 11.3 cm.; B, 8.2 cm., and G. V., 4.6 cm. An electrocardiogram made on the same day revealed P and T waves of normal height (1.0 mm. and 4.0 mm., respectively, in lead 1, and 1.0 mm. and 2.5 mm., respectively, in lead 2). The P-R interval was reduced to 0.18 second. In all, five orthodiagraphic tracings, two teleroentgenograms of the heart, and seven electrocardiograms were made before and during treatment.

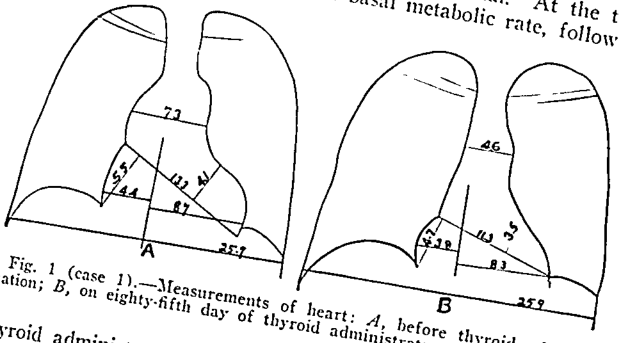

Fig. 1 (case 1).—Measurements of heart: *A*, before thyroid administration; *B*, on eighty-fifth day of thyroid administration.

CASE 2.—A woman, aged 30, single, came to the Out-Patient Medical Clinic of the Beth Israel Hospital complaining chiefly of "feeling cold all of the time." Two and a half years previously she had undergone an operation involving curettage of the uterus, resection of the right ovary, and ventral suspension of the uterus. Since the operation she had felt weak continuously and had tired easily. She had gained 20 pounds (9 Kg.) since the onset of the symptoms and had had continual bilateral tinnitus. About six months prior to admission she had begun to notice a heavy feeling in her head. Several weeks before entrance her friends had remarked that her face was very puffy. She had never had palpitation but during the present illness she had had slight dyspnea on walking rapidly.

The only point of significance in the past history was that she had had recurrent attacks of bronchial asthma during the preceding sixteen years; these attacks had been particularly marked in the winter.

Physical examination disclosed that the patient was moderately obese. The skin was pale, and the face and eyelids were puffy. The skin of the arms and legs was dry, thick and coarse. The hair was sparse and somewhat coarse. The tongue was slightly thickened and broad. There was no cyanosis. The thyroid gland was not palpable. The lungs showed normal resonance, vesicular breath sounds and no râles. The heart was not enlarged to percussion. The heart sounds were distant, the rhythm was regular, and murmurs were absent. The heart rate was 60. There was slight general hyperesthesia of the abdomen, but no masses or organs were palpable. The liver was not felt. The extremities were thickened, and the legs showed slight pitting edema. The blood pressure was 110 systolic and 80 diastolic.

The basal metabolic rate was −44 per cent (Aub-Du Bois standard). The hemoglobin was 62 per cent (Sahli) and the erythrocytes numbered 3,900,000 per cubic millimeter. Examination of the stained blood showed that the erythrocytes were moderately achromic and exhibited moderate variation in size and shape. The differential count was normal. The urine revealed no abnormality. A teleroentgenogram of the heart exhibited a transverse enlargement with blunting of the apex (fig. 3 *A*). The measurements were: MR, 5.2 cm.; ML, 8.8 cm.; TR, 14.0 cm.; internal diameter of the thorax, 24.7 cm. ($\frac{14.1}{24.7}$ = 57 per cent; L, 14.0 cm.; B, 10.8 cm., and G. V., 4.3 cm. An electrocardiogram taken on the same day showed P and T waves of the following heights: $P_1$, 1.0 mm.; $T_1$, 1.5 mm.; $P_2$, 1.0 mm.; $T_2$, 1.5 mm. Gastric analysis disclosed no free hydrochloric acid after the intramuscular injection of 0.5 mg. of histamine. Fractional analysis was done according to the technic of Polland and Bloomfield.[9]

A diagnosis of myxedema and secondary anemia was made. Treatment consisted of the administration of 0.20 Gm. (3 grains) of desiccated thyroid daily and 1 Gm. of iron and ammonium citrate in capsules four times daily.

The patient improved rapidly and the basal metabolic rate became normal. On the sixty-fourth day of observation and of thyroid medication, the basal metabolic rate was +5 per cent. A teleroentgenogram of the heart now showed the following measurements (fig. 3 *B*): MR, 3.6 cm.; ML, 7.7 cm.: TR, 11.3 cm.; internal diameter of the thorax, 24.9 cm. ($\frac{11.3}{24.9}$ = 45 per cent); L, 12.8 cm.; B, 9.9 cm., and G. V., 4.4 cm. The heart sounds improved in quality, appearing much less distant than before treatment. At times a few musical râles were heard in the lungs. The blood pressure varied between 110 systolic, 80 diastolic and 75 systolic, 50 diastolic. The P and T waves in the electrocardiogram became progressively more upright, so that on the seventy-first day of treatment the following measurements were obtained: $P_1$, 1.5 mm.; $T_1$, 5.0 mm.; $P_2$, 2.0 mm.; $T_2$, 4.0 mm. About 3.5 Kg. (8 pounds) of weight was lost during the first ten days of treatment, but after that there was practically no loss of weight. The anemia did not respond to treatment. The skin became smoother and warmer, and the puffiness of the face and lids disappeared. The variations in weight, basal metabolic rate, number of erythrocytes, percentage of hemoglobin, size of the heart, and observations by electrocardiogram are shown in table 2. Symptomatically the patient showed marked improvement. The bowels became regular, whereas previously laxatives had been required daily. The patient felt mentally alert and did not tire so easily as before treatment. Although the attacks of asthma were not lessened, sensitiveness to cold disappeared, and dyspnea on exertion also decreased definitely.

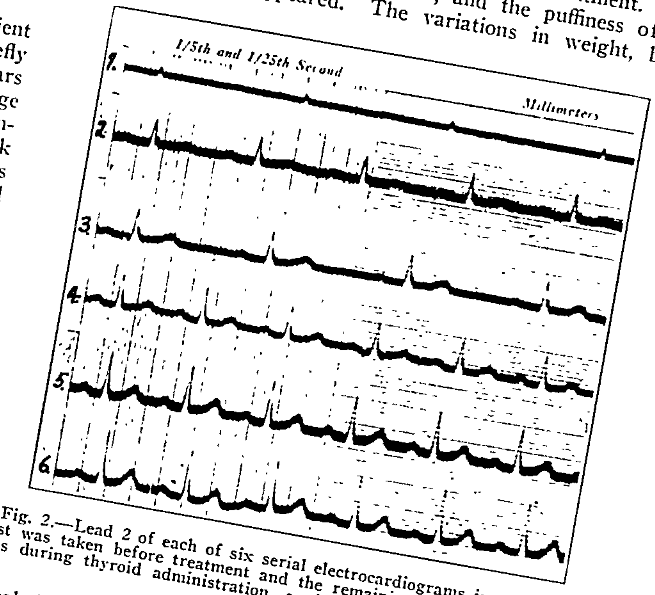

Fig. 2.—Lead 2 of each of six serial electrocardiograms in case 1. The first was taken before treatment and the remaining five at various intervals during thyroid administration, as indicated in table 2.

### COMMENT

The two cases conform to Zondek's original description of "myxedema heart," since the patients exhibited cardiac enlargement, feeble cardiac action under the fluoroscope, slow heart rate, normal blood pressure, and low amplitude of the P and T waves in the electrocardiogram. All were restored to normal with thyroid medication. The one diagnostic feature in both cases was roentgenographic enlargement of the heart, which disappeared when thyroid was administered. The other criteria stressed by Zondek were no more prominent in these cases than in any case of myxedema.

### EXCLUSION OF CERTAIN FACTORS AS POSSIBLE CAUSES OF DECREASE OF CARDIAC ENLARGEMENT

The explanation of the cardiac enlargement and its subsequent disappearance with thyroid medication is complicated by several factors, chief among which are secondary anemia and obesity, both of which are almost invariably associated with myxedema.

1. *Secondary Anemia.*—Decrease in size of the heart has been reported by Ball[10] following improvement of severe secondary anemia. However, as there was no significant improvement of the anemia in our two cases (table 2), this factor may be excluded as an explanation of the decrease in size of the heart. In addition, the anemia was mild in both cases.

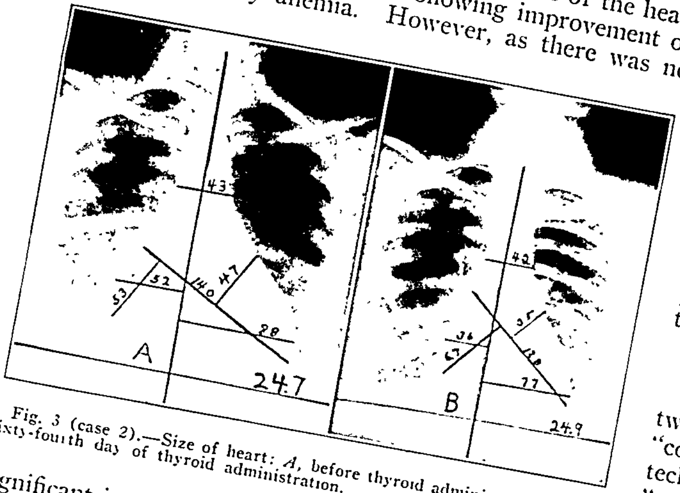

Fig. 3 (case 2).—Size of heart: *A*, before thyroid administration; *B*, on sixty-fourth day of thyroid administration.

2. *Obesity.*—In case 1 the large amount of weight that was lost during treatment (28 pounds, 12.6 Kg.) demands a consideration of the effect which loss of weight by itself may have on the size of the heart. Master and Oppenheimer[11] reported an increase in the size of the heart in 51 per cent of ninety-seven obese patients. Sixty-five of the patients had arterial hypertension. These writers showed roentgenograms of one case to exemplify reduction in size of the heart, which took place with loss of weight. Master and Oppenheimer stated: "This enlargement is probably more apparent than real, in that it is due to the elevation of the diaphragm by the abdominal fat." On the other hand, Scharpff[12] found a distinctly measurable reduction in the true size of the heart following loss of weight of 7 Kg. (15 pounds) or more in obese persons with or without arterial hypertension. He emphasized that the decrease is real and probably due to the disappearance of "compensatory cardiac dilatation" present in his series of obese persons. He was careful to exclude errors due to changes in diaphragmatic and thoracic position in his roentgenograms of the heart. Two thirds of Scharpff's older obese patients exhibited the "compensatory dilatation" of the heart. Scharpff also found that the administration of as much as 0.3 Gm. daily of thyroid had no effect on the size of the heart in both young and old obese persons without myxedema.

It is impossible to say how much of the loss of 28 pounds (12.7 Kg.) in weight in case 1 was due to loss of fluid and how much to loss of body fat, for "the increase in body weight of hypothyroidism is not due entirely to myxedema but in part to increased fat deposit."[13] In case 2, on the contrary, the loss of weight during treatment was slight (10 pounds, 4.3 Kg.) and, according to Scharpff, too small to affect the size of the heart.

3. *Radiographic Technic.*—Aside from organic factors mentioned, the errors inherent in the roentgenographic technic of measuring the heart might give apparent increase or decrease in size. Apparent decrease in size of the heart due to changes in the position of the diaphragm may be excluded in case 1, since variation in diaphragm level was not observed in the five serial orthodiagrams. Furthermore, the width of the thorax in four of the orthodiagrams was constant within a range of 3 mm. (table 2). In case 2, also, the serial teleroentgenograms showed the diaphragmatic position unchanged, and the transverse diameter of the thorax varied only within 2 mm.

### PROBABLE CAUSES OF "MYXEDEMA HEART"

It has been shown that the cardiac enlargement in the two cases reported was not due to secondary anemia, "compensatory cardiac dilatation" of the obese or technical radiographic error. The possible causes of "myxedema heart" in these patients were (1) cardiac dilatation secondary to a flabby heart muscle,[1] (2) a myxedematous condition of the heart itself or of the tissues about the heart, as described by Horsley,[14] and (3) existence of pericardial fluid.[15]

### CHANGES IN THE SIZE OF THE GREAT VESSELS

In case 1 the total width of the great vessels decreased from 7.3 cm. before treatment to 4.6 cm. under thyroid administration. In case 2 there was little or no change in the width of the great vessels. Zondek[1] originally mentioned the occurrence of widening of the great vessels, but he stated that it did not always return to normal under thyroid treatment. Meissner[2] and Fahr[3] also noted the increase in width of the great vessels. Zins and Rösler[3] found that the great vessels decreased in size in proportion to the decrease in size of the heart.

### ELECTROCARDIOGRAPHIC CHANGES

The observed electrocardiographic changes were such as might occur in any case of myxedema, as Means[16] and White[17] have pointed out. In cretinism, likewise, Thacher[18] has reported lowering, flattening, or even inversion of the T wave, which can be brought up to normal by the administration of thyroid. These electrocardiographic changes have not been found in conditions associated with lowered metabolism other than myxedema.[19] The origin of the low amplitude of the auricular (P) and final ventricular (T) waves, was investigated by Nobel, Rosenblüth and Samet,[20] who demonstrated, by the use of needle electrodes placed over the anterior thoracic wall in patients with childhood myxedema, the presence of P and T waves not recorded by the conventional leads from the extremities. They felt that the increased resistance of the skin in myxedema might account for the decreased voltage of the P and T waves of the electrocardiogram. The occurrence, however, of changed auriculoventricular conduction time as indicated by changes in the P-R interval (case 1) cannot be explained on the basis of changes in the skin but rather predicates an actual disturbance within the heart. Case 2 showed no abnormality in conduction time.

### ABSENCE OF CARDIAC INSUFFICIENCY

There was no evidence of heart failure in case 1, either from the history or from the physical examination. In case 2 there was slight dyspnea on exertion before treatment and some improvement of dyspnea after the size of the heart became normal. This dyspnea may have been due to the associated bronchial asthma. The diagnosis of "myxedema heart" in these two patients, therefore, was made without much evidence of heart failure.

This brings up the question Does "myxedema heart" exist without symptoms or signs of cardiac insufficiency? In an analysis of the literature of "myxedema heart" we have noted (table 1) that thirteen (60 per cent) of the twenty-two patients complained of shortness of breath. The symptom of shortness of breath, however, was found by Means[16] to be present in 90 per cent of forty-five patients with myxedema in whom "myxedema heart" was reported as absent. Likewise, Fahr[3] quoted Hirschfelder as writing that myxedema patients, in general, became short of breath on slight exertion. Therefore, either shortness of breath is not a diagnostic symptom of "myxedema heart" or else "myxedema heart" is an extremely common manifestation in myxedema. The literature further indicates (table 1) that less than 30 per cent of the reported cases of "myxedema heart" showed objective evidence of cardiac insufficiency, such as cyanosis, râles at the lung bases, enlarged liver, and pitting edema of the ankles. It seems evident, therefore, that the diagnosis of "myxedema heart" does not require the presence of signs or symptoms of cardiac insufficiency. Indeed, the low level of bodily and circulatory activity in myxedema[21] may prevent the development of severe cardiac symptoms and thereby conceal the presence of "myxedema heart."

### SUMMARY

In two cases of "myxedema heart," both patients had clinical, roentgenographic and electrocardiographic manifestations which were characteristic of the condition as described by previous workers and which became normal after adequate treatment with thyroid. Enlargement of the heart and its return to normal with adequate thyroid treatment is stressed as the one diagnostic feature of "myxedema heart," since the other abnormalities are usually found in all cases of myxedema. Factors other than thyroid medication may decrease the size of the heart during treatment for myxedema. Little, if any, evidence of heart failure was found in either of the cases reported, and hence it is believed that cardiac insufficiency, although sometimes found, is not characteristic of "myxedema heart." The suggestion is made that "myxedema heart" may be more common than is usually supposed, and therefore the need of securing serial teleroentgenograms of the heart and electrocardiograms before and during the treatment of every patient with myxedema is indispensable to exclude the possibility of the presence of "myxedema heart."

# ACUTE APLASTIC ANEMIA COMPLICATING ARSPHENAMINE THERAPY

## REPORT OF A CASE TREATED FOR SYPHILIS COINCIDENT WITH TUBERCULOSIS

I. D. BRONFIN, M.D.
AND
ISIDOR SINGERMAN, M.D.
DENVER

The first to give a clinical description of aplastic anemia was Ehrlich,[1] in 1888, whose patient developed this disease condition following a severe uterine hemorrhage. Many case reports followed with speculative discussions as to whether this form of anemia is a distinct disease entity or a symptom-complex of purpura hemorrhagica. Duke[2] emphasizes that the course and symptoms of this disease depend in the main on which of the three principal blood-forming elements of the bone marrow is mostly affected. The usual symptoms of progressive anemia will predominate when the erythropoietic tissue is chiefly affected; agranulocytosis with subsequent infection, notably angina, when there is failure of regeneration of leukocytes, and purpura with hemorrhage when there occurs a considerable diminution in the blood platelets. This valuable conception is important to bear in mind, since it helps to give a proper appraisal of some of the blood dyscrasias which occasionally follow the use of arsphenamines in the treatment of syphilis.

From a review of the literature on toxic effects from arsphenamines, one gains the impression that in not a few instances was difficulty experienced in making a differential diagnosis between aplastic anemia, agranulocytic angina and purpura hemorrhagica. Farley[3] classified his series of cases under the general heading of "depressed bone-marrow function from the use of arsphenamines," with emphasis on the phenomenon of agranulocytosis. Among his seven cases, one gave the classic blood picture and symptoms of aplastic anemia,

[3] Farley, D. L.: Depressed Bone-Marrow Function from the Arsphenamines, Am. J. M. Sc. **179**: 214-227 (Feb.) 1930.

while the others showed varying degrees of aplasia, as determined by the blood examinations. Of Kastlin's[4] two cases of agranulocytic angina, one developed typical symptoms of purpura hemorrhagica with marked granulopenia after the sixth of a series of injections of neoarsphenamine. There was only a moderate decrease in the erythrocytes and hemoglobin. Moore[5] and his co-workers, who have shown that damage to the bone marrow, as determined by the blood picture, occurs in the majority of nonfatal cases reacting to arsenical drugs, are probably correct when they conclude that "these blood changes differ only in degree from the maximally severe reaction as seen in this case," referring to their report[6] on a fatal case of aplastic anemia following neoarsphenamine treatment.

The confusion that exists with regard to a proper classification of these blood dyscrasias is further shown by Dodd and Wilkinson,[7] who summarize twenty-four cases of "agranulocytic aplasia of the bone marrow" following arsenical medication, including one of their own. Of the total number, twenty-one patients had hemorrhage and twenty had anemia ranging from slight to severe. There was considerable variation in the blood picture. Leukopenia from as low as 136 white cells up to about 4,000 was present in eighteen, normal in two, and 29,000 and 76,000 in two cases, respectively. The polymorphonuclear count was 9 per cent in three cases, from 7 to 13 per cent in six cases, and from 30 to 88 per cent in eight cases. Of the eleven cases with necropsy reports, ten showed hemorrhage, nine aplastic bone marrow and in two the examination was incomplete. The authors very properly comment that there must have been cases other than those included in their table, reported as agranulocytosis, aplastic anemia, arsenic poisoning, purpura and the like, and concede that a specific name has not yet been given to this form of arsenic intoxication. While we have nothing to offer that might clarify this halo of confusion covering the various types of arsenical blood poisoning, we feel that a report of an undoubted case of acute aplastic anemia following arsphenamine medication is justifiable because of its relative rarity. Considering the fact that this complication is nearly always fatal, the prophylactic aspects have not been sufficiently stressed.

According to Stokes,[8] there is no known way of preventing or predicting an acute aplastic anemia, but it is recognized to be a rare complication. Cole[9] and his associates, reporting on 1,212 cases treated for syphilis with a total of 78,350 arsenical injections, had 214 patients presenting toxic manifestations resulting in 12 deaths. No case of aplastic anemia has been observed by them in this series and only two cases of purpura hemorrhagica, in both of which recovery occurred. Stephens[10] reports two cases observed during the past five years in a series of 1,200 patients who received a total of 14,000 injections. In one of the cases he noted evidence of the beginning of active marrow regeneration in the presence of numerous islands of erythroblastic and myeloblastic tissue, but at no time during the month that this patient was under observation was there noted any evidence of such regenerative activity in the peripheral blood. Yet, the author holds out the opinion that there might be some hope for recovery if these patients could be successfully protected from infection. Semenza[11] stresses the gravity of this complication and urges systematic examinations of the blood during arsphenamine treatment in subjects with symptoms of functional deficiency of the blood-making organs. In one of his two cases reported, the administration of arsphenamine had an aggravating effect on the blood dyscrasia previously diagnosed as aplastic anemia. The latter, therefore, cannot be attributed solely to arsphenamine. As a last resort measure, splenectomy was performed in this case without any beneficial results.

The onset of the process may begin within from twelve to forty-eight hours after the injection. It may follow the initial dose or any subsequent dose. Slowly progressive weakness and pallor may precede the hemorrhagic manifestations or the development of stomatitis by one or two weeks. Sometimes there appear a few purpuric spots on the lower extremities or abdomen a day or two after the injection preceding the fatal one. These prodromal phenomena are of great importance and should always be watched for in an individual undergoing active treatment for syphilis. This is especially applicable to the definitely substandard type of patient or the one suffering from another coincident disease.

The distinguishing features of the blood picture in this disease are a moderate or marked decrease in hemoglobin and red cells, a low or normal color index, a progressive leukopenia with a rapid reduction in the granulocytes and a relative increase of lymphocytes, the disappearance of reticulated red cells, the absence of any abnormal cells seen in other types of anemias, and a marked reduction in blood platelets. The clinical course is usually rapid, nonremittent, and lasting rarely more than two or three weeks, although the average duration of the so-called primary or idiopathic types of aplastic anemia, according to Schneider,[12] have an average duration of six months. The tendency to early hemorrhagic manifestations is quite characteristic. Slight epistaxis, slight bleeding from the gums or an insignificant conjunctival hemorrhage may be the first symptom to alarm the patient sufficiently to bring it to the attention of the physician. As the disease progresses, there is manifest bleeding from nearly all mucous membranes. Fever may appear early or late; it sometimes dates its onset following a blood transfusion. Hyperpyrexia is the rule toward the end and is probably due to bronchopneumonia, which is a frequent terminal complication. Purpuric spots, most numerous over the skin of the anterior and posterior aspects of the chest, arms and forearm, may fade in one area and appear in another. In the mouth these purpuric spots often coalesce and undergo ulceration. When hematemesis is present and blood in the stools appears, abdominal pain may be marked, but there is no hepatic or splenic enlargement.

The treatment is chiefly prophylactic. A history of any previous reaction calls for painstaking vigilance during the entire course of treatment. The slightest

purpuric manifestation is an indication for at least a temporary discontinuance of the drug. Frequent blood counts may give early evidence of abnormal bone marrow function and constitute a warning for greater caution. The early administration of sodium thiosulphate is of doubtful therapeutic value but should be used as a routine. Blood transfusions are disappointing, as are likewise calcium and the various commercial coagulants, such as fibrinogen or thromboplastin. The results obtained by Stockton and Franklin[13] in a case of purpura hemorrhagica from the use of antivenin caused us to use this product in the amount of 10 cc. intramuscularly without any effect on the hemorrhagic symptoms.

The following report is illustrative of the salient points in the clinical picture described:

C. B., a man, aged 32, admitted to the National Jewish Hospital, Sept. 3, 1930, complained of weakness, impaired appetite, slight cough and expectoration. He had had pulmonary disease for two years, for which he received active treatment in institutions. An examination showed moderately advanced pulmonary tuberculosis involving both upper lobes with probable infraclavicular cavitation on the right. The sputum was positive; a Wassermann test of the blood was 4 plus; a blood count showed slight anemia.

The clinical course was progressive with malaise, increasing weakness, irregular fever, ranging from 99.2 to 101 F., and vague intestinal symptoms. Accordingly, pneumothorax was induced on the right side, Nov. 15, 1930. Despite a satisfactory compression of the diseased lung area, the case pursued an unfavorable course. In the belief that syphilis hindered recovery, antisyphilitic treatment was instituted. He had previously received two courses of treatment in other institutions with neoarsphenamine alternating with preparations of bismuth and mercury. The Wassermann reaction of the blood after the first course had become negative. The last injection of neoarsphenamine was given, July 1, 1930, and was followed by a pruritic, papular rash over the extremities which cleared in one week. Our treatment began, Jan. 4, 1931, and consisted of twelve injections of neoarsphenamine in doses of from 0.3 to 0.6 Gm. at intervals of from five to seven days, the total amount of the drug being 3.75 Gm. Improvement in the patient's condition occurred, the temperature reached normal, and the sputum diminished.

The course was uneventful until, following the injection of 0.3 Gm., February 25, there appeared the next day a discrete nonpruritic erythematous papular eruption over the extremities and trunk. The patient thought the eruption was similar to that which occurred in July, 1930; it was, therefore, not seriously regarded. However, following the injection of March 2, the eruption assumed the character of purpura. Petechial hemorrhages appeared on the right conjunctiva, upper lip and buccal mucosa. Slight bleeding from the nose followed. Preceding and following the last treatment, the patient complained of dull headache, weakness, slight epistaxis and transient attacks of dizziness. The temperature was normal. There was marked pallor, although it was noted in retrospect that this had already been present for some time and had been gradually increasing during the preceding two weeks.

March 7, five days after the last injection of neoarsphenamine, hematologic studies, as shown in the accompanying table, revealed a severe anemia, a leukopenia with relative lymphocytosis, and prolonged bleeding time. These results were interpreted at first as evidence of severe arsenical intoxication; 0.5 Gm. of sodium thiosulphate was at once administered intravenously, followed by two similar doses at twelve hour intervals, and a generous liver diet instituted. Two days later, the blood changes were more pronounced. The erythrocytes were normal in size and shape. Achromia was absent. No nucleated red cells were seen. A definite diagnosis of aplastic anemia was made. A transfusion of 500 cc. of citrated blood, March 9, failed to produce any important change in the clinical picture. Despite a marked pallor, he felt well and was calm. Petechial hemorrhages appeared at this time in the skin over the trunk and extremities. These, in the course of a few days, would fade and then reappear in other areas. New crops of petechiae appeared in the mucous membrane of the gums, lips, tongue and cheek. Bleeding from the gums and nose occurred intermittently. Transfusions were given again, March 11 and 13. The one given on the latter date caused some improvement in the blood picture, although the percentage of neutrophils remained distinctly reduced, and blood platelets were absent. Purpuric manifestations continued. March 14, the patient complained of soreness in the mouth and throat. Hemorrhagic areas appeared on the right tonsil and gradually increased in extent on the sixteenth. A fetid odor to the breath was present. Up to this time his general condition was satisfactory. Except for a febrile reaction of 104 F. following the third transfusion, his temperature averaged 99.4 F., the pulse 96. There were few subjective complaints, except for a gradually increasing dyspnea.

However, from March 17 onward, his condition rapidly declined. The temperature fluctuated between 102 and 105 F., and the pulse between 120 and 140. Malaise and weakness increased. His color became chalk white. The hemorrhagic areas in the throat spread. They coalesced over the left tonsil, which became swollen and ulcerated. Several petechiae on the left border of the tongue coalesced and became ulcerated. Hemorrhage into the vitreous was noted on the nineteenth. In the evening of the same day he was given 10 cc. of antivenin intramuscularly. This resulted in a marked diminution of the bleeding time, but the hemorrhagic symptoms continued. Swallowing became extremely painful. Epistaxis continued freely. The vomitus was bloody and the stools were tarry. A transfusion, March 20, was followed by a febrile reaction of 108 F. A distressing cough developed and was productive of bloody sputum. Drowsiness, stupor and, finally, muscular twitching set in. The last transfusion was given, March 24, and death occurred two hours later.

---

[13] Stockton, M. R., and Franklin, G. C. H.: Antivenin Therapeusis in Purpura, J. A. M. A. **96**: 677-678 (Feb. 28) 1931.

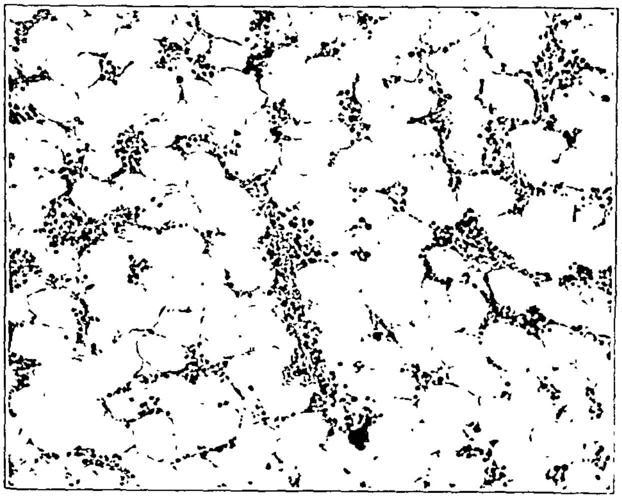

Fig. 1.—Section of bone marrow from the sternum, reduced from a photomicrograph with a magnification of 135 diameters. Hematoxylin and eosin stain. In this illustration and in figure 2, the marrow is largely fatty and shows no hyperplasia; myeloid cells and nucleated red cells are present in small numbers; lymphocytes and plasma cells are more numerous than in normal marrow; there is no edema or hemorrhage.

The observations at necropsy as reported by Drs. William C. Johnson and William Black of the University of Colorado School of Medicine were as follows:

1. Aplasia of bone marrow.
2. Anemia.
3. Purpuric hemorrhages in the skin of the face, neck and thorax.
4. Hemorrhage into the abdominal muscles.
5. Hemorrhage into the mucosa of the stomach, the pelvis of the left kidney and the bladder.
6. Chronic pulmonary tuberculosis, bilateral and nodular.
7. Partial atelectasis of the right lung with pneumothorax.

Sections from the anterior ends of the ribs near the costochondral junctions showed rarefaction of the cells lying in the interstices of the adipose tissue, of which there was a considerable amount. The erythropoietic elements, megakaryocytes and megaloblasts, were very few in number. Sections from the sternum were similar in appearance to those from the ribs. Owing to the haste necessary in performing this autopsy, bone marrow from other locations was not obtained.

### COMMENT

The etiology of primary aplastic anemia is not known. It is a disease of young adults. Since many subjects frequently give a history of preceding pallor, a congenital defect of the bone marrow has been suggested by some as a predisposing factor. Although our patient did show a moderate pallor, the condition of the blood was essentially normal on admission, except for a slight degree of secondary anemia. However, there was noted a gradually increasing pallor, especially during the two or three weeks preceding the fatal dose of neoarsphenamine. It is not unlikely that earlier blood studies would have revealed alterations in the normal ratio of the cellular elements to constitute a warning to modify the treatment.

According to Musser and Wintrobe,[14] chronic intoxication with chemical poisons is responsible for secondary aplastic anemia. Selling's[15] experimental and clinical studies of benzene poisoning led many observers to attribute the arsenical intoxications to the double benzene ring which the arsphenamines contain, but so far it has not been proved that these compounds liberate free benzene when injected into the circulation. Yet, Dodd and Wilkinson[7] could not find a case of such aplasia of the bone marrow following the administration of arsenic not containing the benzene ring. In comparison with the wide use of the arsphenamines, depressed bone marrow function, and especially aplastic anemia, is indeed very rare. There must therefore exist idiosyncrasies which, in many instances, give prodromal manifestations, such as pruritus, pallor, malaise and evanescent purpuric eruptions. In our case, the last three symptoms were present but their significance was not recognized.

To what extent the coincident tuberculosis was a factor is a matter of speculation. That the syphilitic infection was active was demonstrated by the positive Wassermann reaction of the spinal fluid obtained post mortem. As the clinical manifestations were out of proportion to the pulmonary lesion, antisyphilitic treatment was deemed indicated.

### SUMMARY AND CONCLUSIONS

In a case of acute arsenical aplastic anemia, terminating fatally in twenty-two days, treatment was primarily for pulmonary tuberculosis, but the syphilitic infection apparently retarded recovery. The history of a cutaneous rash during a previous course of arsphenamine treatments gave the patient and ourselves a sense of false security. The inescapable conclusion is that a patient under arsphenamine medication should have frequent blood examinations, even in the absence of any untoward manifesations, and the drug should be immediately discontinued as soon as such symptoms as malaise, pallor, itching of the skin and purpuric manifestations are noted.

# RENAL CARBUNCLE IN INFANCY

MEREDITH F. CAMPBELL, M.D.
Attending Urologist to the Babies' and New York Nursery and Child's Hospitals; Assistant Attending Urologic Surgeon, Bellevue Hospital
NEW YORK

Renal carbuncle, so called because of its anatomic semblance to carbuncle elsewhere, is a localized massive suppuration within the kidney due to bacterial metastasis (usually staphylococcus), often produces marked toxemia, is rarely uncomplicated, is difficult to diagnose and, unrecognized or inadequately treated, entails a high mortality. Discussion of the lesion is found more often in surgical textbooks than in the literature; less than fifty cases have been reported. I have been unable to find a record of its occurrence in infancy. The two cases herewith reported, a boy and girl each admitted to the hospital at the age of 8 weeks with renal carbuncle and perirenal abscess and subsequently operated on, are unique because of the tender age of the patients. However, they are here described more especially because they forcibly demonstrate by specific example an insufficiently recognized principle of medical practice, namely, that infants and children are subject to practically every form of urologic disease which one is accustomed to associate with adult life, and, when clinical manifestations indicate a thorough urologic examination or radical urosurgical treatment, extreme youth is no contraindication. Nor does the clinical picture differ vastly in juveniles and adults.

## ETIOLOGY AND PATHOLOGY

Although renal carbuncle may occur at any age, its incidence is highest in the fourth and fifth decades. The incidence in males is twice that in females; the lesion is more often found on the right side. Renal injury, whether by external blow, stone or urinary stasis, predisposes to carbuncle. The direct cause is bacterial metastasis, predominantly staphylococcal, from a focus elsewhere, usually the skin (furunculosis, carbuncle, paronychiae, abrasion, wound), but may originate in an osteomyelitis, oral infection and the like. In my two cases furunculosis preceded. In case 1 this condition was a chief complaint on admission to the hospital.

The bacterial embolus arrives hematogenously and localizes in the parenchyma, usually toward a kidney pole; a metastatic abscess results with leukocytic infiltration, necrosis and, by the establishment of secondary circumferential foci, extension. The lesion may spread peripherally elevating the cortical contour and, with or without actual capsular perforation, commonly causes secondary perinephritis or perinephric abscess. While the site of the initial localization has been variously described, the character of the gross lesion suggests interlobular artery embolism with suppurative involvement, chiefly of the cortex peripheral thereto. Usually the remainder of the organ appears surprisingly normal; most rarely are two carbuncles found. Moreover, the lesion is characteristically unilateral; bilateral lesions have been described only twice. In one of my patients (case 2) a similar metastatic lesion involved the adjacent suprarenal medulla (fig. 5).

If the bacterial virulence is low or the local tissue resistance high, the abscess may become walled off and ultimately be replaced by scar or calcification; more likely, it will spread as previously described.

## SYMPTOMS

The symptoms are those of infection: toxemia, fever, often chills, sweats, gastro-intestinal upsets, anorexia, nausea or vomiting, loss of weight, and pain. The latter is usually most acute in the costovertebral angle. Rarely, localizing symptoms are absent. Sometimes the kidney is palpable, but more often the fixed mass of perinephritis or perinephric abscess will be found. Urinary disturbances are usually absent.

The preoperative diagnosis of renal carbuncle is exceedingly difficult; few times has it been correctly made. It is suggested by a history of cutaneous suppuration within the past few weeks, a loin mass, tenderness in the costovertebral angle, fever and, as a rule, repeated sweats. A marked leukocytosis with high polymorphonuclear count quite regularly exists. These manifestations are common to perinephric abscess also and thereby increase the differential diagnostic difficulties. In case 1 carbuncle and furunculosis coexisted; in case 2 furunculosis antedated carbuncle one month.

Urinalysis reveals little; a mild infection with pyuria may be found. As a rule, the urinary manifestations are disproportionate to the degree of renal involvement unless, perchance, the abscess has established drainage into the pelvis. An abundance of casts commonly means marked toxic nephritis of the better kidney. Ureteral catheterization usually discloses good renal function with or without infected urine. In a few instances pyelography has shown pelvis displacement, compression or distortion. Renal tumor was diagnosed preoperatively in case 2 (fig. 3). In case 1 the pelvis of the involved organ was greatly displaced (fig. 1). A plain roentgenogram may reveal an enlarged kidney or with perinephric abscess, obliteration of the isolateral psoas muscle outline and a lumbar spinal concavity.

Seldom can carbuncle be differentiated from acute suppurative pyelonephritis or acute multiple renal abscess. If the lesion directly underlies the peritoneum, intraperitoneal disease—appendicitis, cholecystitis, salpingitis or peritonitis—is commonly misdiagnosed. If signs of peritoneal irritation are lacking, the patient may be treated for grip, influenza, typhoid or, with subphrenic suppurative extension, diaphragmatic pleurisy or pneumonia. The diagnosis is most often made at the time of renal exploration for perinephric abscess. As a corollary, with a thorough inspection of the entire kidney surface when a perinephric abscess is being drained, a renal carbuncle will more often be recognized. On the other hand, as in both cases here reported, one may feel that the extreme condition of the patient does not warrant extensive exploration at the initial operation.

## TREATMENT

Frequently, the severity of the local disease, the general toxemic manifestations and an advanced toxic nephritis of the better organ demand nephrectomy. If the patient is a good surgical risk, renal decapsulation with incision and drainage or excavation of the carbuncle may be performed. In a few instances the "core" of the lesion has been found separated and is easily extracted. Emergency reoperation with nephrectomy is often demanded when the more conservative methods are employed; the surgical risk is then greatest. An associated perinephric abscess must be liberally drained and, if one is going to be conservative, coexistent urinary obstruction appropriately eliminated.

---

From the Babies' Hospital (Departments of Pediatrics and Surgery, College of Physicians and Surgeons, Columbia University) and the Pediatric Service of New York Nursery and Child's Hospital, Dr. O. M. Schloss, director.

In a statistical summary of forty-seven cases, Moore[1] found that primary nephrectomy was performed in twenty-one cases, with two deaths; incision and secondary nephrectomy in seven, with no deaths, incision and drainage only in thirteen, with two deaths; incision and secondary excision of the carbuncle in two, with no deaths, and enucleation of the carbuncle in two instances with secondary nephrectomy in one, with one death. Therefore, when the general condition of the patient or of his better kidney permits, primary nephrectomy appears to be the safer procedure.

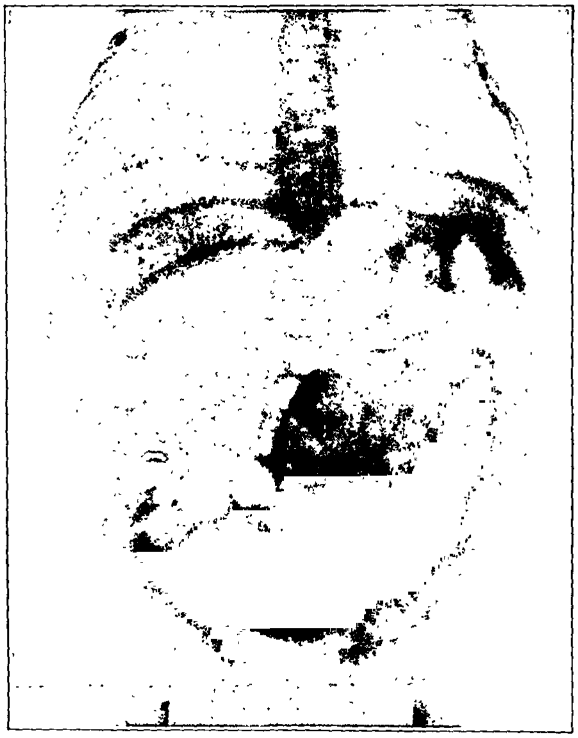

Fig. 1 (case 1).—Marked left renal displacement mesially by complicating perinephric abscess. The pelvic outlines are normal, affording no indication of existent carbuncle.

REPORT OF CASES

Case 1.—*History*.—I. T., a girl, aged 8 weeks, was admitted to New York Nursery and Child's Hospital, April 8, 1931, because of furunculosis, chronic constipation and a left loin mass of three weeks' duration. Moreover, she had failed to regain her birth weight of 8¼ pounds (3,742 Gm.).

Furunculosis of the chest and back had existed since the age of 3 weeks. Many of the lesions had been incised and drained. For three weeks previous to admission there had been no bowel movement without an enema. During this time the mother noted a left loin mass. Birth and family history were negative.

*Examination*.—The patient was markedly emaciated and anemic; she looked sick. The skin was thin and covered with dry furuncles over the chest and back. Both ear drums were reddened. The pharynx, heart and lungs were normal. The abdomen was distended. There was a bulging of the left side due to a large, oval, firm, fixed, smooth surfaced mass filling the entire loin. The remainder of the abdomen was tympanitic. Rectal examination revealed a fixed mass high in the left lower quadrant.

Urinalysis revealed: hazy and alkaline urine; specific gravity, 1.014; albumin, a trace; sugar, 0; acetone, a trace; white blood cells, 1 to 2 per high power field; culture, Staphylococcus albus. Blood count revealed: red blood cells, 3,460,000; hemoglobin, 60 per cent; white blood cells, 46,950; polymorphonuclears, 58 per cent; large lymphocytes, 19 per cent; small lymphocytes, 12 per cent; transitionals, 11 per cent.

April 20, a roentgen series of the gastro-intestinal tract showed medial displacement of the descending colon with marked spasticity. April 23, a barium enema showed a spastic descending colon.

April 28, a cystoscopy was done without an anesthetic. The bladder urine was hazy. There was mild cystitis and trigonitis. Both ureters catheterized easily. Indigo carmine, injected intravenously, appeared in deep concentration from each side in five minutes. A left pyelogram was made and revealed a normal pelvis with mesial displacement (fig. 1). A specimen from the left ureter showed an occasional leukocyte. Culture yielded Staphylococcus albus. A specimen from the right ureter was normal.

The diagnosis was perinephric abscess. During this period the temperature ranged between 100 and 103 F., with continued loss of weight. Two preoperative blood transfusions were given.

*Operation and Result*.—April 30, an operation for perinephric abscess was performed. The usual loin kidney incision was made and drainage was done. About 2 ounces of foul smelling pus was evacuated. The abscess was found to engulf the kidney. The organ was not explored because of the extreme condition of the patient. Two cigaret drains were inserted with closure. Culture of the perirenal pus yielded Staphylococcus albus and B coli.

Following the operation, the child was doing well for several days when the loin drainage became unsatisfactory. The wound was reopened, but a gradual downward course with slowly rising temperature and loss of weight led me to believe that renal suppuration probably existed. A preoperative transfusion was given and another operation performed, June 4. Loin exploration and nephrectomy was done. The child at this time weighed 6 pounds 3 ounces (3,107 Gm.). The kidney showed a typical carbuncle of the upper outer pole (fig. 2) with locally elevated cortical surface. The remainder of the organ was normal.

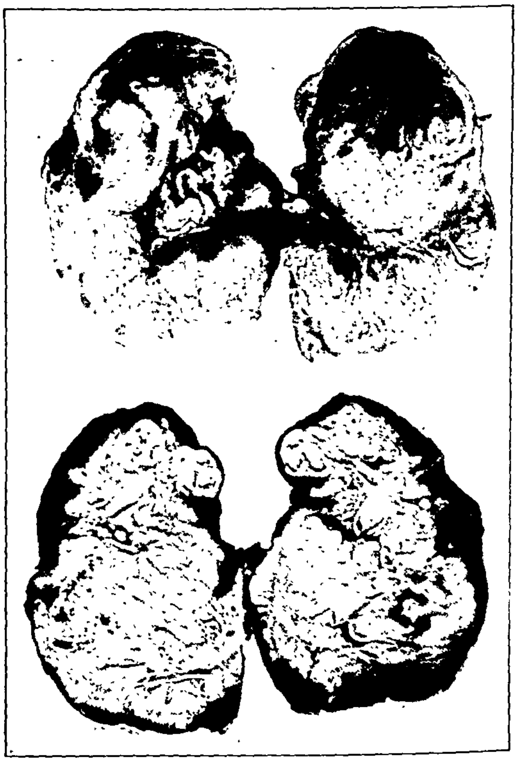

Fig. 2 (case 1).—External and section appearance of carbuncle. The cortical elevation is admirably shown, as is the intrarenal process. The remainder of the organ appears normal.

---

[1] Moore, T. D.: Renal Carbuncle, J. A. M. A. **96**: 754 (March 7) 1931.

Postoperatively the child did poorly, suffering marked vasomotor collapse and abdominal distention. Death occurred on the sixth day with a temperature of 107 F. During the six-day interval two transfusions were given and, during the course of the surgical period, numerous hypodermoclyses. Blood taken shortly before death showed nonprotein nitrogen 400 mg. per hundred cubic centimeters. Autopsy was refused. Because I wished to preserve the kidney specimen in its entirety, histologic studies were not made.

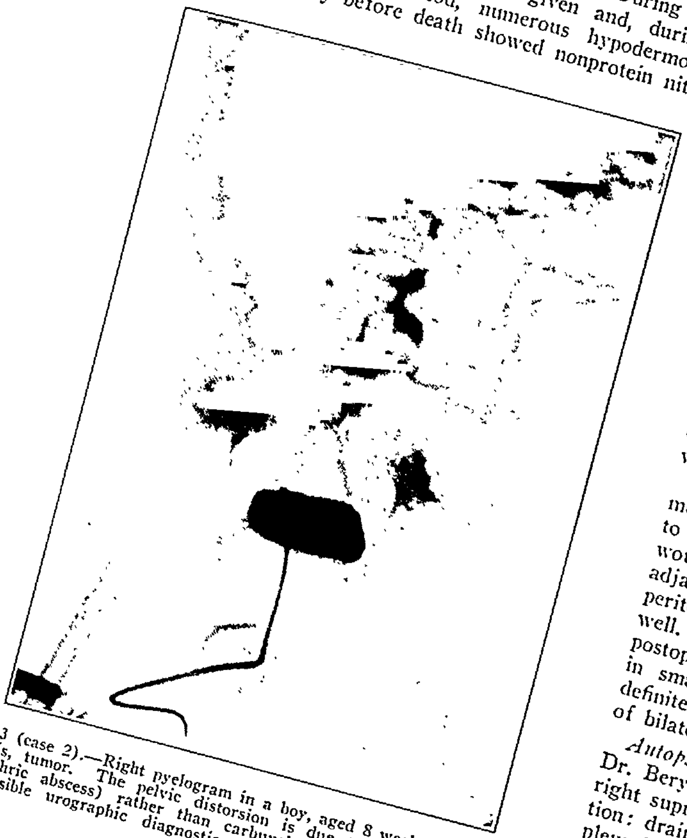

Fig. 3 (case 2).—Right pyelogram in a boy, aged 8 weeks. Urographic diagnosis, tumor. The pelvic distorsion is due to extrarenal pressure (perinephric abscess) rather than carbuncle (compare with figure 5). The possible urographic diagnostic difficulties in renal carbuncle are apparent.

Case 2.—*History.*—E. S., a boy, aged 8 weeks, was admitted to Babies' Hospital, Feb. 25, 1931, because, for the past two weeks, all feedings were vomited and the abdomen was enlarged and hard. Subsequently, it was learned that shortly before the present onset the child suffered furunculosis of the back. The child, born at term, had been delivered with forceps and was breast fed for one month.

*Examination.*—Physical examination revealed a protuberant abdomen with a well rounded, slightly nodular fixed mass felt in the right loin extending from the umbilicus laterally to the back and from the costal margin to the iliac crest. The temperature was 102.2 F. The remainder of the physical examination was negative.

The laboratory examination revealed a nasopharyngeal culture positive for thrush. Urinalysis revealed: acid urine; specific gravity, 1.018; albumin, a marked trace; sugar, 0; acetone, a marked trace; diacetic acid, 0; scattered leukocytes. Nonprotein nitrogen of the blood was, 27.8 mg. per hundred cubic centimeters. A phenolsulphonphthalein test showed first hour, 22.5 per cent; second hour, 12.5 per cent. Blood count revealed: red blood cells, 2,200,000; hemoglobin, 48 per cent; white blood cells, 13,950; polymorphonuclears, 68 per cent; lymphocytes, 24 per cent; eosinophils, 3 per cent; mononuclears, 1 per cent; myelocytes, 2 per cent; myeloblasts, 2 per cent.

February 26, intravenous urography was done. A film taken one and a half hours after the injection of iopax showed a normal left renal pelvis. The right pelvis was larger than normal; the calices were blunted. Cystoscopy was done, March 3. A sugar-ball anesthesia was given. Cystoscopically the bladder was normal. The catheter was passed 10 cm. up the right ureter without difficulty; a ureteral specimen was collected and a pyelogram made (fig. 3). Because the intravenous urogram indicated a normal appearing left organ and because of the delicate condition of the baby, left catheterization was not done. Indigo carmine intravenously did not appear from the right side in ten minutes' observation. The right ureter specimen showed pus + + and hemolytic Staphylococcus albus.

*Operation and Result.*—On the basis of the physical examination and the pyelogram, a renal tumor was diagnosed, a transfusion given and an operation performed, March 5. Expecting to perform a nephrectomy for a large renal tumor, I did a right transperitoneal exposure (T-shaped), rectus margin rib to iliac crest with median extension 6 cm. posteriorly toward the spine. In the loin, free pus was released and from 1 to 1½ ounces evacuated. Digital exploration revealed an extensive perinephric abscess with marked induration and friability of the fatty tissue. As I felt that the local pathologic changes and precarious condition of the patient did not justify extensive exploration, two cigaret drains were inserted and the wound was closed.

Postoperatively the wound drained freely and the child did moderately well for six days when, during a dressing, he began to cry. Massive evisceration through the infected abdominal wound resulted. Overlapping closure was done at once. The adjacent bowel in the right loin was densely adherent to the peritoneum overlying the abscess site and to the wound line as well. Scant reaction followed this closure operation; three days postoperatively, yellow feces appeared medially in the wound in small amounts. There was moderate distention but no definite signs of peritonitis. The child died eleven days later of bilateral bronchopneumonia.

*Autopsy.*—This was performed by Dr. Martha Wollstein and Dr. Beryl Page. The anatomic diagnosis was abscess of the right suprarenal and kidney; right perinephric abscess; operation: drainage of perinephric abscess; fibrosis, peritoneal and pleural adhesions; fecal fistula; bilateral bronchopneumonia; hemosiderosis of the liver and the spleen.

The stomach and intestine were enormously distended and there were numerous filmy adhesions everywhere between the coils of intestine. Dense adhesions were present beneath the surgical wound and the underlying coils of intestine and a probe could be passed through the opening in the wound into the lower ileum. The intestinal wall at this site was closely bound to the lateral abdominal wall by dense adhesions. Free exudate was not present. The umbilical vein was closed.

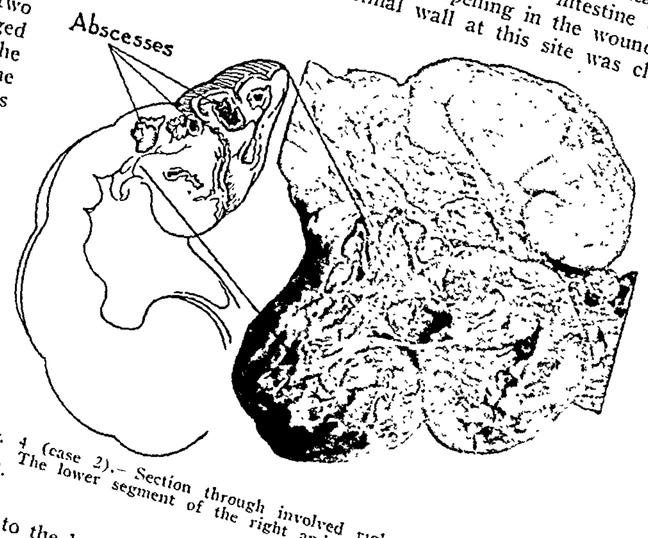

Fig. 4 (case 2).—Section through involved right kidney and suprarenal. The lower segment of the right and the entire left kidney are normal.

The base of the right lung was adherent to the diaphragm. Acute exudate was not present. The right lung showed incomplete separation of the upper and middle lobes both anteriorly and posteriorly. The anterior half of the lung was pale pink and well aerated, showing some lobules which were emphysematous along the anterior margin. The posterior half of both upper and lower lobes was purplish red, showing numerous subpleural hemorrhages. It was densely consolidated. This consolidation was most extreme in the upper lobe. The left lung showed complete separation of its two lobes. The upper lobe was pale pink and well aerated. The main portion of the lower lobe was similar to the upper lobe. The posterior part of the lower lobe was purplish red and slightly firm.

The liver was purplish red and of normal size. On the lower margin of the anterior surface were scattered small white plaques evidently of organized exudate. On section the liver appeared normal.

The intestine, which was distended, contained some fluid brownish fecal material. Numerous fibrous adhesions occurred on the serosal surface. In the ileum 15 cm. above the ileocecal valve there was a fistula opening into the surgical incision on the skin. The appendix, colon and rectum were normal.

In the tissues posterior to the right kidney was a heavy fibrinopurulent exudate and a little free pus, and the organ was densely adherent to the inferior surface of the liver. When the capsule was stripped away from the right kidney, a zone of fibrinopurulent exudate lay on the capsule extending outward from the pelvis of the kidney. There was also exudate on the posterior surface of the kidney. In other regions the capsule stripped readily from the kidney, leaving a surface on which the fetal lobulations were well marked. On section the kidney measured 4.5 cm. in length by 2.8 cm. in width. The upper pole appeared to be compressed beneath the right lobe of the liver. The cortex measured 2 mm. in width. In the lower half of the kidney near its medial surface was an abscess measuring about 4 mm. In the upper pole of the kidney in its medial portion were several abscesses, the largest measuring 3 mm. in diameter. These lay in both the cortex and the medulla. The pelvis was slightly dilated but was free from exudate. The right ureter appeared normal.

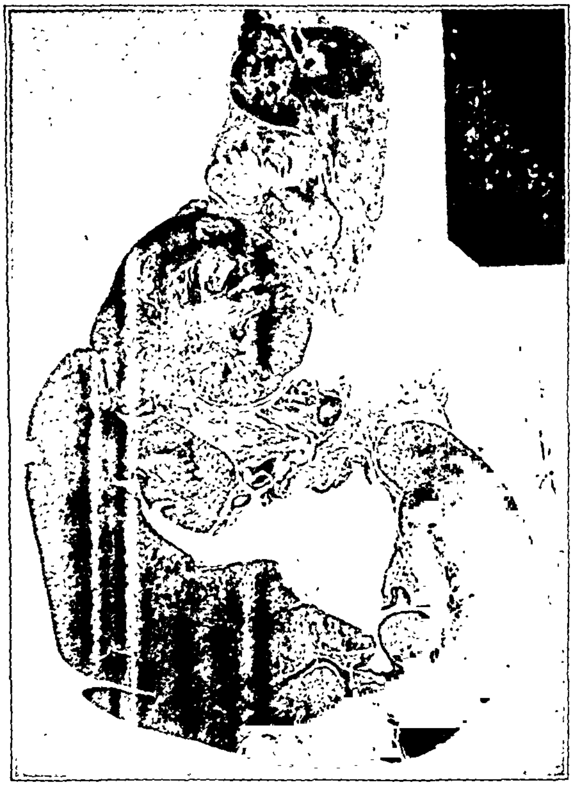

Fig 5 (case 2).—Section of entire right kidney and suprarenal. The character of the parenchymal lesion is well shown; freedom from involvement elsewhere in the organ is noteworthy.

The right suprarenal was adherent to the medial surface of the upper pole of the right kidney. The connective tissue over it showed tiny hemorrhages. The organ was firm and rounder than normal On section two abscesses, the largest 7 mm in its greatest width, lay in the central portion of the suprarenal. The suprarenal measured 2 cm. in width by 1 cm. in thickness. At one point the suprarenal and kidney seemed to be in direct contact. Elsewhere the suprarenal and kidney were joined by a zone of translucent, connective tissue and there was a thin layer of pus apparently lying between the main portion of the suprarenal and the kidney.

The left kidney measured 6 cm. in length and 3 cm. in width. The capsule stripped readily, leaving a pale surface on which the fetal lobulations were deep. On section the cortex and pyramids were of normal widths. The organ appeared slightly pale and was somewhat soft. The pelvis and ureter were normal. The left suprarenal was of average size. On section it showed a pale medulla and a central zone which measured about 1 mm. in width. It was brownish red. The bladder was normal. The bodies of the vertebrae adjacent to the perinephric abscess were normal.

Specimens from the left kidney were normal.

In the upper pole of the right kidney, in the portion of the organ adjacent to the suprarenal were several large abscesses made up of poorly preserved polymorphonuclears and surrounded by large numbers of vacuolated mononuclear cells. Large circumscribed masses of mononuclear cells extended far out into the neighborhood kidney substance, replacing both tubules and glomeruli. In the surrounding interstitial tissue were lymphocytes and plasma cells, and the surrounding tubules were filled with cytoplasmic and nuclear débris and contained a few polymorphonuclears. Clumps of yellowish brown pigment were numerous. Over the region containing the abscess the capsule of the kidney was not sharply demarcated but the tissue between the kidney and the suprarenal was densely infiltrated with large vacuolated mononuclears with fewer lymphocytes and plasma cells among them, and there was a large abscess in the perirenal connective tissue. In the neighboring part of the suprarenal several large abscesses occurred. These lay mainly in the central part of the gland. About them were zones of dense hyaline tissue, infiltrated with scattered lymphocytes and plasma cells. A well marked medulla was present in the remainder of the gland, and the intermediate zone was congested and contained small hemorrhages and necrotic cortical cells. Several extracortical fetal rests were present.

The pelvis of the kidney was wide, but in the section the entire pelvic lining was not present. That which was present appeared normal and a section of the ureter was normal.

The blood vessels in the section were normal.

A gram stain of the section showed masses of gram-positive staphylococci in the abscesses. Many of the leukocytes showed phagocytosis of the bacteria.

A smear from the kidney abscess yielded Staphylococcus aureus, nonhemolytic. A culture of the blood was made from the heart's blood. A smear from the culture yielded pneumococci and B. coli. A blood plate from the culture yielded B. coli.

## COMMENT

The usual course of staphylococcus metastasis to the kidney from a cutaneous infection and the development of carbuncle occurred in both of the cases reported. In case 2, the history of antecedent furunculosis was not obtained until after the operation. The subsequent clinical courses in both instances suggest that even though the patient is extremely ill and the surgical risk is great, a more extensive exploration at the initial operation is justifiable since extensive renal suppuration may exist. Certainly, continued fever and toxemia following liberal incision of a perirenal abscess indicates a thorough renal exploration.

In case 2 a most erroneous preoperative diagnosis was made. Perirenal suppuration was not seriously considered because the loin mass felt extremely hard, like a solid renal tumor. The temperature and the moderate leukocytosis were disregarded since, in children especially, they are commonly present with renal neoplasia The pyelogram (fig. 3) suggests a tumor and indicates a large kidney; in an adult with hypernephroma I have seen what is almost a urographic reduplication of the pelvic outlines in this infant. The pyelograms in neither case 1 nor 2 suggest renal carbuncle. The diagnostic difficulties are apparent.

While the extreme youth and the rarity of clinical recognition of renal carbuncle renders these patients and their lesions of unusual interest, the cases are recorded more particularly to emphasize that (1) infants and children are subject to grave urologic diseases; (2) the clinical picture is quite identical with that of similar lesions in adults; (3) when indications for urologic examination or radical urosurgical treatment exists, they should be liberally employed, and (4) to these procedures a tender age is no contraindication.

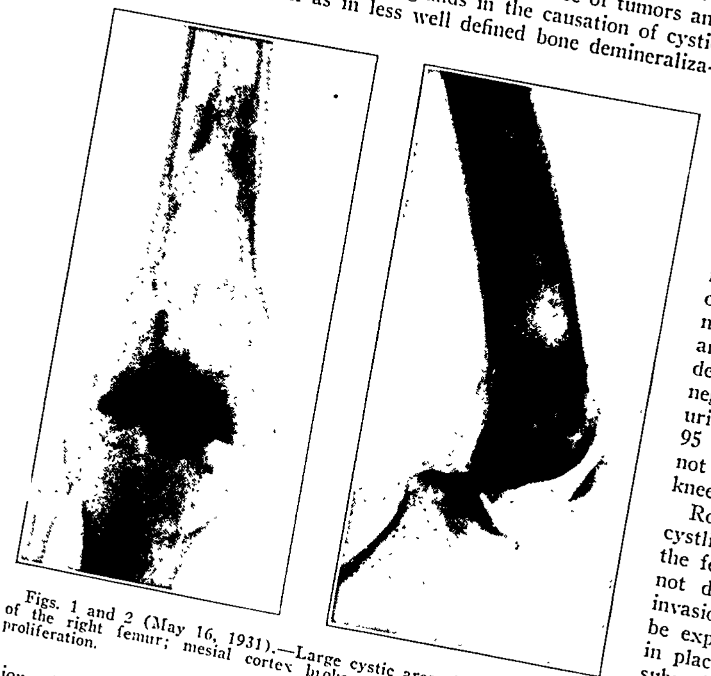
140 East Fifty-Fourth Street.

## *Clinical Notes, Suggestions and New Instruments*

### IRRADIATION OF THE PARATHYROIDS IN CYSTIC DISEASE OF THE BONES

Edwin A. Merritt, M.D., Washington, D. C.

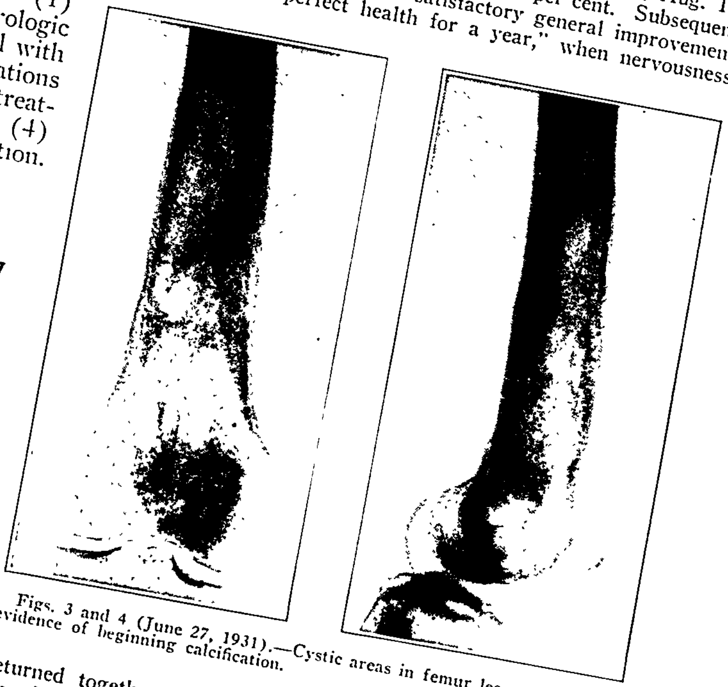
Endocrinologic study has demonstrated a definite relation between the parathyroid glands and the metabolism of calcium in the skeletal body, which seems to have been first noted by Erdheim in 1903. Since then other observers, including Verbitz, Langhams, Schlagenhaufer, Gunther and Mandl, have eported cases to substantiate the direct influence of tumors and hyperplasia of the parathyroid glands in the causation of cystic one disease as well as in less well defined bone demineralization.



Figs. 1 and 2 (May 16, 1931).—Large cystic areas in the distal third of the right femur; mesial cortex broken down with periosteal bone proliferation.

The case that we are reporting points to the possibility of cure of certain cystic diseases of bone by roentgen irradiation of the parathyroids, and no record of a similar case influenced by irradiation can be found in the literature.

A white woman, aged 34, unmarried, referred to the radiologic clinic by Dr. Bullock of Washington, D. C., was admitted to Garfield Hospital by ambulance, May 16, 1931. The family history was unessential. She had had the usual diseases of childhood. She had always been well up to January, 1928, when symptoms of hyperthyroidism developed. In addition to the cardinal signs there was a loss of weight of 40 pounds (18 Kg.), insomnia, nausea and vomiting, and marked weakness. Prior to the subtotal thyroidectomy, which was performed, Aug. 14, 1928, the basal metabolic rate was plus 23 per cent. Subsequent to the operation there was a satisfactory general improvement to the point of "perfect health for a year," when nervousness



Figs. 3 and 4 (June 27, 1931).—Cystic areas in femur less conspicuous; evidence of beginning calcification.

returned together with all the previous symptoms of hyperthyroidism, which were thought by the patient to be "more severe than before the operation." In addition, she complained of increasing stiffness and pain in the right knee, which finally, with symptoms of hyperthyroidism, produced complete disability.

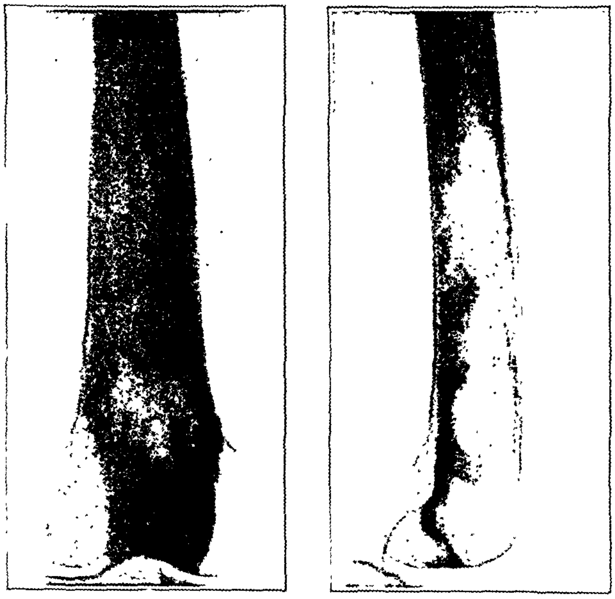
The patient was emaciated, and was very nervous and apprehensive. The temperature was 98.6 F.; the pulse, 98; the respiration rate, 20. There was a pronounced tremor of the fingers, and slight bilateral exophthalmos. There was a scar of a previous thyroidectomy with a rather firm bilateral moderate enlargement of the thyroid above the scar. The heart and lungs were normal. The abdomen and viscera presented no demonstrable abnormality. The Wassermann reaction was negative. The basal metabolic rate was plus 35 per cent. Blood, urine and calcium determinations were not done. She weighed 95 pounds (43 Kg.). The right leg was semiflexed and could not be manipulated without producing excruciating pain in the knee joint. The knee was slightly swollen.

Roentgenograms of the right knee (figs. 1 and 2) showed cystlike areas of bone destruction involving the distal end of the femur with some periosteal proliferation. The cortex was not definitely expanded nor did it have the appearance of invasion by malignant process. The periosteal reaction might be explained by the fact that the cortex was broken through in places, resulting in egression of fluid material through the subperiosteal spaces, with resulting bone proliferation. Examination of the chest and skull showed no abnormality. Two areas of the neck, including the thyroid and parathyroid areas, were irradiated in the following dosage: 5 ma., 135 kilovolts, 10 inch distance, with 5 mm. of aluminum filter. June 6, 1931, three weeks after the first treatment, there was rather noticeable improvement in the patient's condition. There was some gain in weight, less nervousness, and a decrease in pulse rate (90). The pain in the right knee had disappeared almost entirely. Further roentgen treatment was given to the same areas with the same dosage. June 27, symptoms of hyperthyroidism showed marked improvement. Pain in the right knee had entirely disappeared. The patient was able to walk comfortably and felt very well. Roentgenograms of the right knee showed marked regeneration of bone in the cystic areas previously noted

---

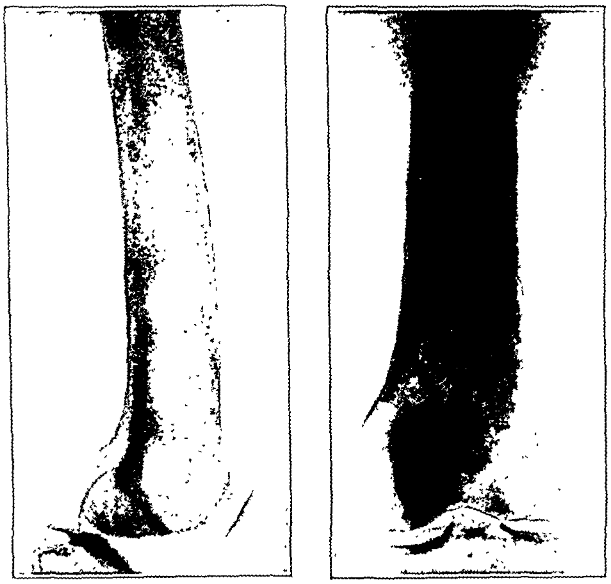
From the Radiological Clinic of Drs. Groover, Christie and Merritt.

(figs. 3 and 4). Further roentgen treatment was administered with *the same dosage to the thyroid and the parathyroids.* August 8 there was still further improvement. There was a marked gain in weight; the patient now weighed 116 pounds (52.6 Kg.). The symptoms or disability were no longer noticeable in the right knee. Roentgen treatment was administered to the thyroid and the parathyroids in the same dosage.



Figs. 5 and 6 (Aug. 29, 1931).—Additional calcification of cystic areas: normal architecture of bone appearing.

August 29, the patient felt well but was slightly nervous and had a slight tremor. There were no symptoms from or discomfort in the knee. Roentgen treatment was again administered to the thyroid and the parathyroids in the same dosage. Roentgenograms of the knee (figs. 5 and 6) showed still further new bone formation in the cystic areas. September 19, the patient weighed 120 pounds (54.4 Kg.); tremor had disappeared, and she was much less nervous. One more treatment to the thyroid and the parathyroids was advised at this time. October 12, when the patient returned for roentgen examination of the knee (figs. 7 and 8), there was scarcely a trace of the original bone lesion or of hyperthyroidism.



Figs. 7 and 8 (Oct. 12, 1931).—Scarcely any evidence of previous cystic areas; architecture of bone nearly normal.

## REMOVAL OF MASSIVE VASCULAR FIBROMA BY ELECTROCOAGULATION

A. F. Tyler, M.D., and K. L. McShane, M.D., Omaha

The bloodless removal by electrocoagulation of a large tumor, so vascular that several attempts at surgical removal had failed because of hemorrhage, indicates the value of this method.

The tumor was large. It is the only one of this size, attached to the side of the face, reported in the literature.

*History.*—Miss A. M., an unmarried white woman, aged 33, complained of a large tumor on the right side of the face. The patient stated that instrumental delivery at birth resulted in injury to the right eye and deformity of the right orbit. At 3 months of age, the right eye was removed on account of festering of the eyeball. At 4 years of age, the late Dr. Harold Gifford, Sr., of Omaha removed a growth from the right eyelid and counseled against any future surgery to any tumorous growth of that region. At 5 years of age, multiple painless tumors of varying size began to develop all over the body. At 7 years of age, an attempt was made to remove a small tumor of the right supra-orbital region. At 15 years of age, a blood vessel in the right side of the neck was tied off and another attempt made to remove the tumor, which had gradually increased in size. The body was generally covered by soft, painless, movable tumors, pea sized to walnut sized, which caused no discomfort. However, the tumor in the right supra-orbital region slowly increased in size until it became very heavy. In March, 1931, another attempt at surgical removal was made but abandoned because of hemorrhage. The surgical wound healed, but in a short time the skin ulcerated and broke open on the lateral inferior surface and began a serosanguineous drainage. Following the operation, the tumor immediately took on a rapid growth and since the middle of August had increased tremendously in size until, November 26, it was approximately 18 inches (45 cm.) long by 10 inches (25 cm.) wide by 8 inches (20 cm.) thick.

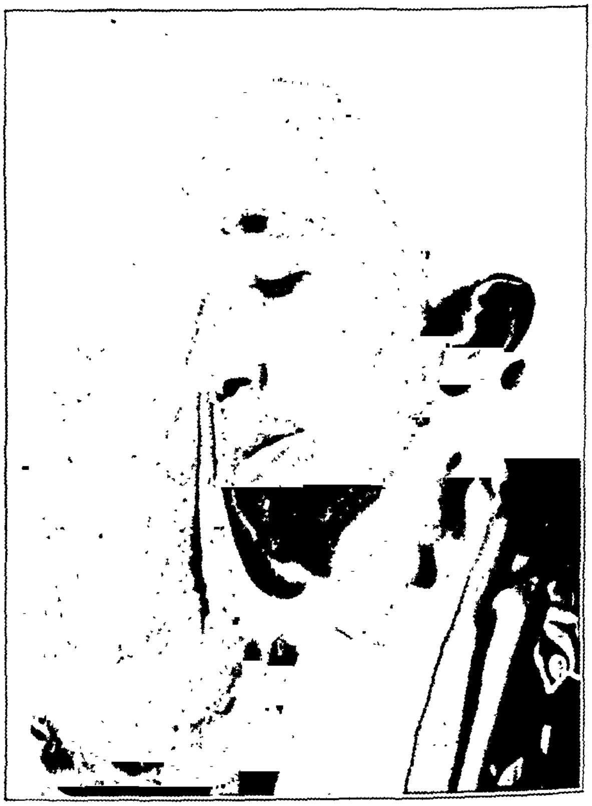

Fig. 1.—Tumor from the left side. The long vertical cleft in the skin is the elongated right palpebral fissure, the margins of which opened and closed when the left eye blinked.

---

From the Tumor Clinic of Swedish Immanuel Hospital.
Read before the Immanuel Hospital staff meeting, Jan. 8, 1932.

*Examination.*—The patient was emaciated; she had lost 20 pounds (9 Kg.) from the middle of August to Nov. 26, 1931. Her skin was hot and dry (temperature 102) and studded with tumors, varying in size from that of a pea to that of a small orange, all over the body, including the scalp and the soles of the feet. One tumor about 0.5 by 1.5 cm. was attached to the buccal surface of the margin of the right upper gum.

From the entire right half of the face was suspended the large tumor. On the lower third of the lateral surface was an ulcerative, draining, exuberant mass with a horizontal and medial vertical cleft, extending up under the tumor surface for about 4 inches (10 cm.), and lined by necrotic tissue, giving off an offensive odor. On the medial surface of the tumor was a vertical cleft, lined with mucous membrane, about 4 inches (10 cm.) long, located in the medial third of the tumor, which twitched with the blinking of the left eye and was apparently the distorted right palpebral fissure.

The blood count revealed: Hemoglobin, 55 per cent; red blood cells, 3,600,000; white blood cells, 34,000; polymorphonuclears, 90 per cent; small lymphocytes, 7 per cent; large lymphocytes, 3 per cent. The urine was normal; the Wassermann test was negative.

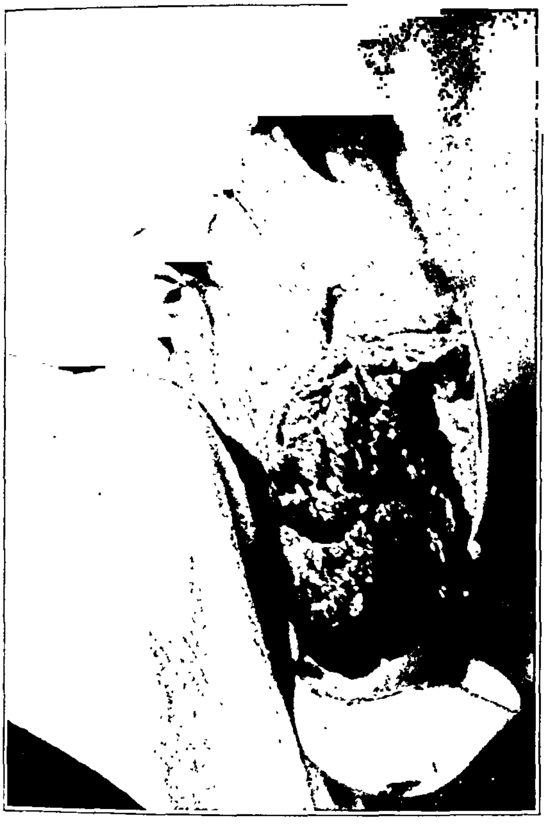

Fig. 2.—Tumor from the right side. Projecting are the ulceration and a large denuded tumor mass. The scars in the skin above the ulcerated area are marks at previous attempts at surgical removal.

The clinical diagnosis was neurofibromatosis with probable sarcomatous degeneration of the tumor on the right side of the face.

*Operation and Result.*—Following a preliminary hypodermic with one-sixth grain (0.011 Gm.) of morphine sulphate, "Avertin" was administered by rectum, 80 mg. per kilogram of body weight being used. This anesthetic was chosen because of the absence of fire hazard when electrocoagulation is used about the face. Aware of the size of the venous spaces which had made previous attempts at surgical removal fail, we used electrocoagulation, the current chosen being one of relatively low frequency, low voltage and high amperage. In order to increase the heat further, two pointed active electrodes were used. These were placed in contact with the tissue about 1.5 cm. apart and held in one position long enough to coagulate the tissue but not to char it. An adjacent area was then coagulated. This process was continued until the entire thickness of the skin and underlying tumor mass were coagulated across, the coagulated band being about 2.5 cm. wide. With one hand on each side of this coagulated band, gentle pressure was made so as to pull the tumor apart. The coagulated tissue easily separated. In this manner we were able to coagulate the vascular spaces and vessels before severing them, making a bloodless operation of it.

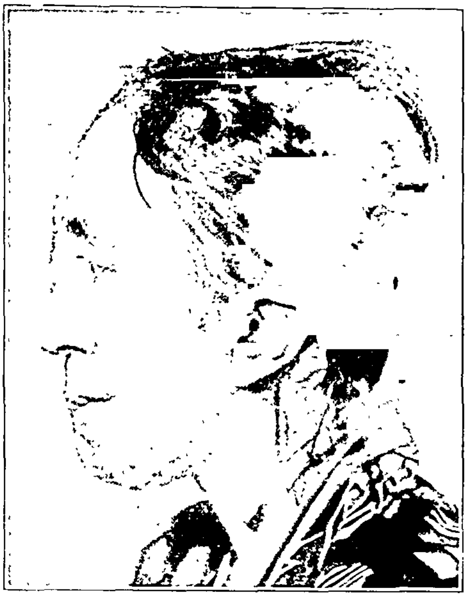

Fig. 3.—The left side of the face after removal of the tumor by electrocoagulation.

The coagulated tissue, attached to the proximal side of the wound, separated off in about one week, after which healthy granulations appeared. After the granulations were in a proper condition a plastic operation was done to close the defect as well as possible, although complete closure could not be made. The remaining defect was allowed to fill in by granulation and epidermization.

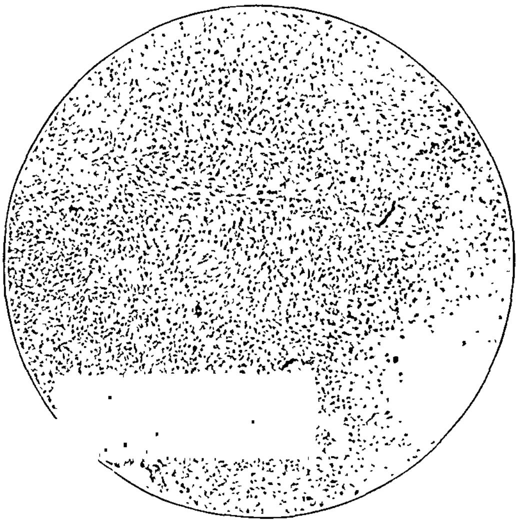

Fig. 4.—Section of tumor tissue showing the connective tissue fibers characteristic of fibroma molluscum.

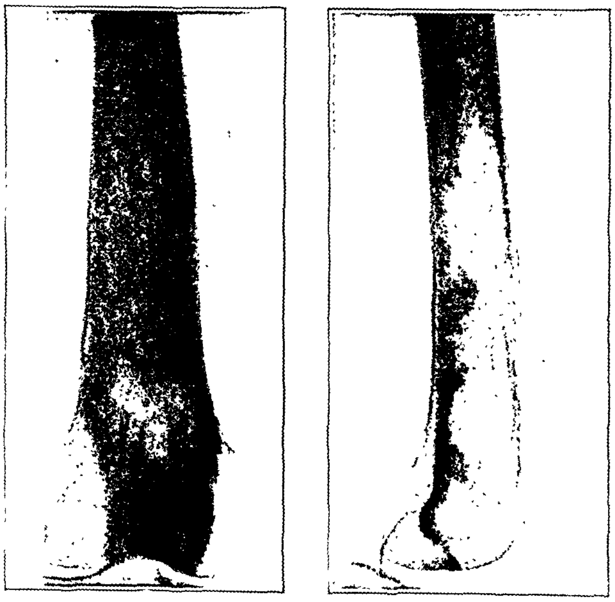
The integument over the tumor was thickened to 4.5 cm. The superficial veins were about 1 cm. in diameter and the subcutaneous tissue contained large venous spaces so that hemostasis was impossible with hemostatic forceps. The technic described enabled us to coagulate this tissue, producing thrombi in the venous spaces before they were opened. The coagulated (figs. 3 and 4). Further roentgen treatment was administered with the same dosage to the thyroid and the parathyroids. August 8 there was still further improvement. There was a marked gain in weight; the patient now weighed 116 pounds (52.6 Kg.). The symptoms or disability were no longer noticeable in the right knee. Roentgen treatment was administered to the thyroid and the parathyroids in the same dosage.



Figs. 5 and 6 (Aug. 29, 1931).—Additional calcification of cystic areas: normal architecture of bone appearing.

August 29, the patient felt well but was slightly nervous and had a slight tremor. There were no symptoms from or discomfort in the knee. Read before the Immanuel Hospital staff meeting, Jan. 8, 1932.

*Examination.*—The patient was emaciated; she had lost 20 pounds (9 Kg.) from the middle of August to Nov. 26, 1931. Her skin was hot and dry (temperature 102) and studded with tumors, varying in size from that of a pea to that of a small orange, all over the body, including the scalp and the soles of the feet. One tumor about 0.5 by 1.5 cm. was attached to the buccal surface of the margin of the right upper gum.

From the entire right half of the face was suspended the large tumor. On the lower third of the lateral surface was an ulcerative, draining, exuberant mass with a horizontal and medial vertical cleft, extending up under the tumor surface for about 4 inches (10 cm.), and lined by necrotic tissue, giving off an offensive odor. On the medial surface of the tumor was a vertical cleft, lined with mucous membrane, about 4 inches (10 cm.) long, located in the medial third of the tumor, which twitched with the blinking of the left eye and was apparently the distorted right palpebral fissure.

The blood count revealed: Hemoglobin, 55 per cent; red blood cells, 3,600,000; white blood cells, 34,000; polymorphonuclears, 90 per cent; small lymphocytes, 7 per cent; large lymphocytes, 3 per cent. The urine was normal; the Wassermann test was negative.

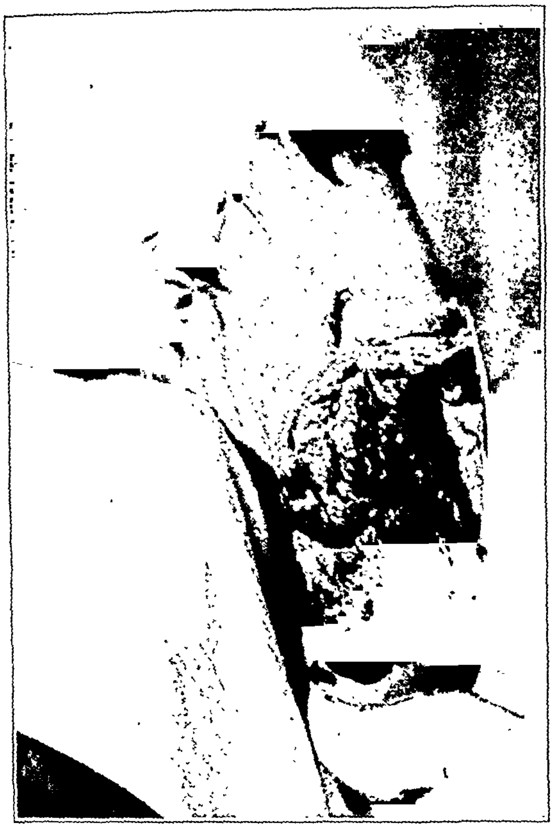

Fig. 2.—Tumor from the right side. Projecting are the ulceration and a large denuded tumor mass. The scars in the skin above the ulcerated area are marks at previous attempts at surgical removal.

The clinical diagnosis was neurofibromatosis with probable sarcomatous degeneration of the tumor on the right side of the face.

*Operation and Result.*—Following a preliminary hypodermic with one-sixth grain (0.011 Gm.) of morphine sulphate, "Avertin" was administered by rectum, 80 mg. per kilogram of body weight being used. This anesthetic was chosen because of the absence of fire hazard when electrocoagulation is used about the face. Aware of the size of the venous spaces which had made previous attempts at surgical removal fail, we used electrocoagulation, the current chosen being one of relatively low frequency, low voltage and high amperage. In order to increase the heat further, two pointed active electrodes were used. These were placed in contact with the tissue about 1.5 cm. apart and held in one position long enough to coagulate the tissue but not to char it. An adjacent area was then coagulated. This process was continued until the entire thickness of the skin and underlying tumor mass were coagulated across, the coagulated band being about 2.5 cm. wide. With one hand on each side of this coagulated band, gentle pressure was made so as to pull the tumor apart. The coagulated tissue easily separated. In this manner we were able to coagulate the vascular spaces and vessels before severing them, making a bloodless operation of it.

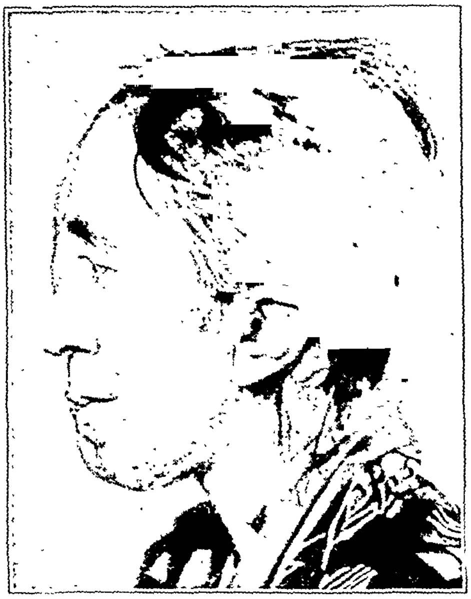

Fig. 3.—The left side of the face after removal of the tumor by electrocoagulation.

The coagulated tissue, attached to the proximal side of the wound, separated off in about one week, after which healthy granulations appeared. After the granulations were in a proper condition a plastic operation was done to close the defect as well as possible, although complete closure could not be made. The remaining defect was allowed to fill in by granulation and epidermization.

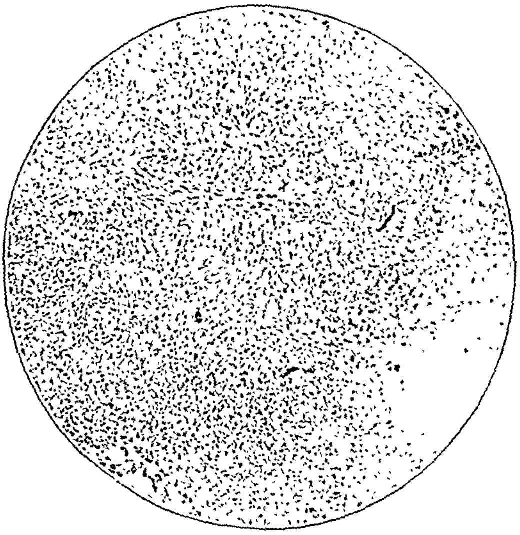

Fig. 4.—Section of tumor tissue showing the connective tissue fibers characteristic of fibroma molluscum.

The integument over the tumor was thickened to 4.5 cm. The superficial veins were about 1 cm. in diameter and the subcutaneous tissue contained large venous spaces so that hemostasis was impossible with hemostatic forceps. The technic described enabled us to coagulate this tissue, producing thrombi in the venous spaces before they were opened. The coagulated tissue was then pulled apart without cutting and without bleeding. The tumor itself was almost devoid of blood supply, there being only an occasional artery and vein of small size. The tumor was very firm except in the central portion, where there were several abscess cavities. The largest of these measured 10 cm. in diameter and was draining out through the ulcerated area on the postero-inferior surface of the mass. Another abscess cavity measured 5 cm. in diameter and two others each 2.5 cm. in diameter.

The tumor was attached to the periosteum of the skull in the right temporal region. The thin areas in the skull bone were due to pressure atrophy of the outer table accompanied by deformity from the heavy tumor pulling downward and outward, instead of tumors in the orbit pressing outward, as we had thought before operation.

Besides the one large tumor there were numerous smaller ones in the subcutaneous tissues of the remaining flaps. On removal, these were firm, nonvascular and of the same color as cartilage.

Dr. H. E. Eggers made the microscopic observations. The material throughout consisted of connective tissue fibers, irregularly interlaced, and of a uniform stage of advanced fibroblastic development, without evidence of excessively active division. Nerve filaments could not be detected.

The microscopic diagnosis was fibroma.

This disease is often spoken of as multiple fibromatosis.

### SUMMARY

It would appear that there are four general divisions of symptomatology of von Recklinghausen's disease, or fibroma molluscum:

1. Tumors of the skin.
2. Tumors of the nerves.
3. Pigmentations of the skin.
4. Functional disturbances.

# CLUBFOOT

F. C. Kidner, M.D., Detroit

The cure of congenital clubfoot has always presented a difficult problem. In spite of many recognized methods of treatment, unsatisfactory results are still common. Such failure results in a greater or less degree of physical handicap which is lifelong in its effects.

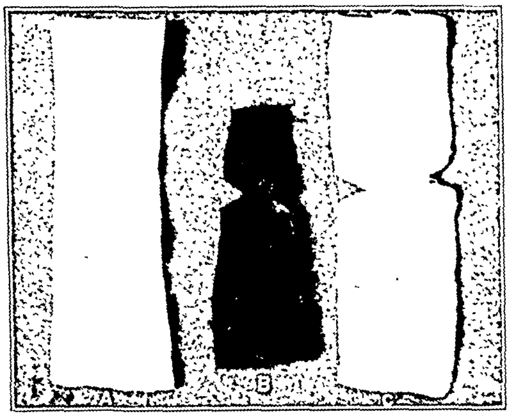

Fig. 1.—*A*, single thickness flannel next skin; *B*, felt pad for sole and heel; *C*, plaster-of-paris posterior mold cut for heel.

The three principal causes of failure are delay in the inauguration of treatment, imperfect nerve supply of the muscles, and failure to obtain complete overcorrection of the deformity. Fortunately, the first cause through education of the general practitioner is rapidly disappearing. Nowadays it is generally recognized that, the earlier treatment is undertaken, the better the chance for real cure. The second cause, as in cases of spina bifida, is and always will be a complication. Its presence offers a special problem which requires radical and long continued measures for its solution. The third cause, which is the most common, results from faults in the method of treatment used, or from lack of thoroughness in its application.

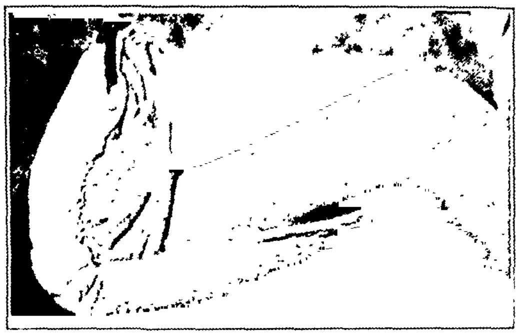

Fig. 2.—Padded posterior mold in place and hardened in corrected position.

Because it is difficult to obtain and maintain complete overcorrection to the extent of reversing the deformity by any form of treatment in common use, I am emboldened to add one more procedure to the many already recognized. It is intended for use on feet that are still sufficiently flexible to be overcorrected by manipulation. This procedure is relatively simple, is efficient, and avoids the common dangers of interference with the circulation of the foot and of pressure sores. The materials used are easy to handle and are obtainable anywhere. They are inexpensive. Plaster of paris, felt padding and flannelette are all that are required. The procedure is as follows:

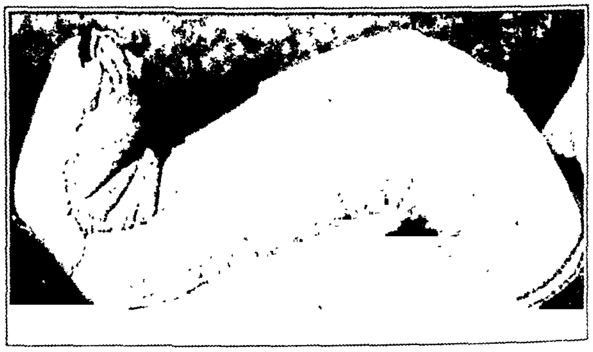

Fig. 3.—Rest of leg wrapped with bias flannel bandage.

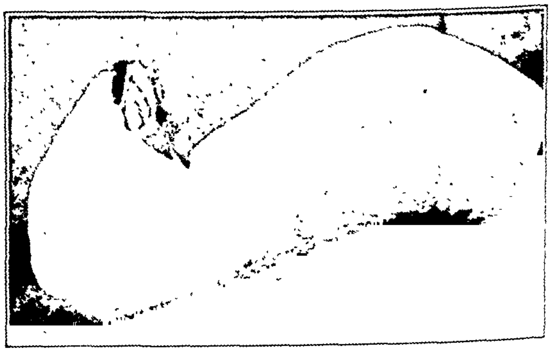

Fig. 4.—Lateral view of plaster completed.

A full overcorrection, which means correction to the point at which the dorsum of the foot can be brought in contact with

---

From the Orthopedic Department of the Children's Hospital of Michigan.

the anterior surface of the leg, is obtained by manipulation carried out, except in very young infants, under a general anesthetic. This full overcorrection is sometimes obtained at the first trial, but more frequently two or more trials are necessary.

When it has been accomplished, a posterior plaster-of-paris mold long enough to extend from a point one-half inch beyond the ends of the toes around the heel to the upper limit of the calf, and one inch wider at the lower extremity than the width of the forefoot, is made. At the heel of this mold, two V shaped cuts are made in the side of the mold to prevent wrinkling. On top of the mold is placed a thin felt pad also cut to fit the heel. On top of this a soft layer of flannelette is placed. While still soft, this mold is bandaged to the sole of the foot and back of the calf with the flannelette layer in contact with the skin. During the process of hardening, the surgeon holds the foot in full overcorrection of the plantar flexion of the foot and of the adduction of the forefoot, care being taken to prevent squeezing of the toes together. As the mold has been cut wider than the sole of the foot, its turned up medial edge acts as a shelf against the inner side of the big toe to maintain the correction of the forefoot adduction. When the mold is hardened, it alone serves to maintain the correction. In order to hold the mold in place, the whole lower leg and thigh are bandaged with flannelette and then enclosed in circular plaster of paris with the knee at right angles. This circular plaster is carried around the sole of the foot without enclosing the front of the ankle. When the dressing is complete the whole dorsum of the foot and the front of the ankle are visible, so that there is no possibility of pressure in these regions. Thus the only obstruction to circulation is the fat and skin of the patient's foot where it wrinkles over the dorsum.

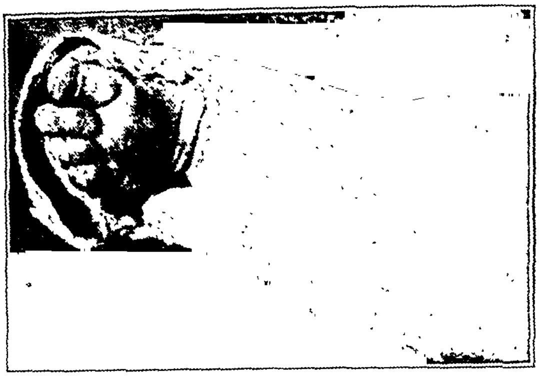

Fig. 5.—Anterior view of plaster completed, showing entire absence of pressure over anterior surface of foot and ankle with strong overcorrection. Also shelf on posterior plaster mold which prevents varus of the forefoot.

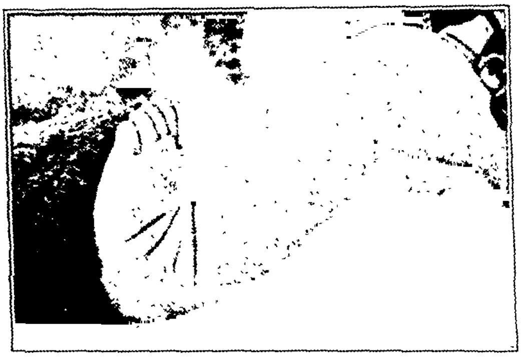

Fig. 6.—Amount of overcorrection easily maintained.

The advantages of this method are that it allows constant inspection and avoids all possibility of external pressure. The illustrations are self explanatory.

1337 David Whitney Building.

## FRACTURE OF THE ELBOW

James Warren Sever, M.D., Boston, and H. Quimby Gallupe, M.D., Waltham, Mass.

This case is reported for two reasons: first, because of its excellent functional and anatomic result, in spite of totally unorthodox treatment, and, second, because of its exemplification of Wolff's law, or the law of "bone transformation."

Wolff's law is as follows: Every change in the form and function of the bones, or of their function alone, is followed by certain definite changes in their internal architecture, and equally definite secondary alterations of their external conformation, in accordance with mathematical laws.

One of the corollaries of Wolff's law is that of "functional shape." The external force and internal architecture are determined by function alone.

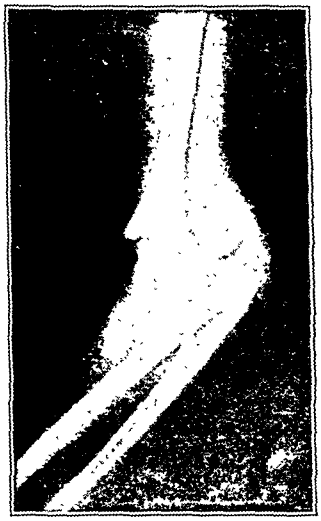

Fig. 1.—June, 1928: note backward displacement of lower end of humerus.

### REPORT OF CASE

J. M. C., a boy, aged 8 years, fell, June 10, 1928, and fractured his right elbow. A roentgenogram showed a supracondylar fracture which was at once reduced perfectly, but swelling and loss of radial pulse necessitated change of position of the elbow, and consequent loss of reduction of the fragments. This was necessary to preserve the hand and lower arm. As a result of the swelling, the skin in the bend of the elbow gave way, and there resulted for some time an open wound exposing the muscles but not communicating with the joint itself.

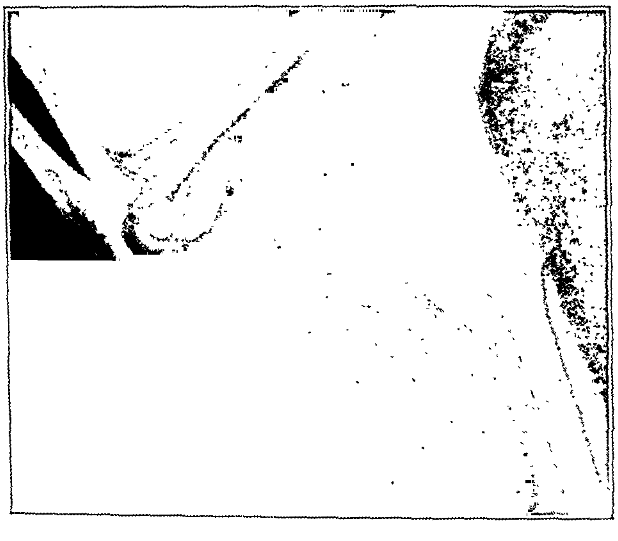

Fig. 2.—June 31, 1928: note new bone; displacement of lower fragment uncorrected.

We saw the child in consultation about a week later. An attempt was made at that time to reduce the fracture, but on account of the continued swelling and the open wound it was abandoned. An internal angular splint was applied and advice was given to leave the elbow as it was until the wound had healed and the swelling subsided. A roentgenogram taken the day of the accident shows the condition of the fracture, with the backward displacement of the lower fragment. There was also considerable lateral displacement (fig. 1).

The swelling disappeared and the skin healed. A roentgenogram, taken June 31, still showed considerable backward and lateral displacement of the lower fragment. There was a definite bridge of new bone uniting the fragment to the back of the shaft of the humerus (fig. 2).

The splint was omitted as soon as the wound had healed, and the elbow was held as fully flexed as possible for about three weeks, following which freedom was advised. The child also submitted to physical therapy three times a week for several months, but no forcible passive motions were made.

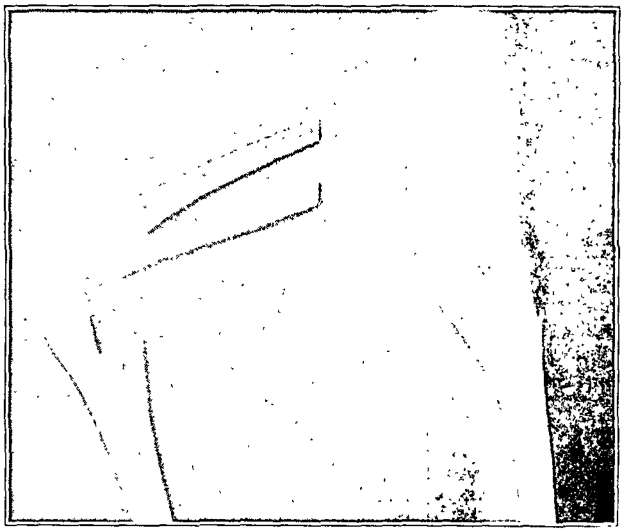

Fig. 3.—September, 1928: solid union; beginning absorption of proximal end of humerus.

In September, 1928, a tracing showed 55 degrees flexion and 120 degrees extension (fig. 3). The roentgenogram at this time showed solid union of the two fragments. There was marked absorption of the distal end of the proximal fragment, and the lateral displacement was becoming much less marked. These changes were due, we believe, to functional use alone.

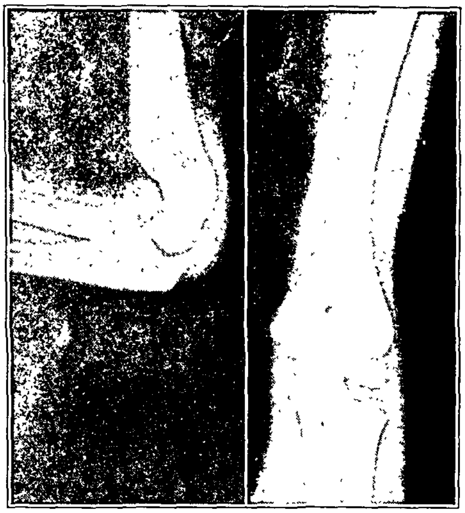

Fig. 4.—September, 1931: three years after fracture; normal function and motion; almost complete absorption of lower end of humerus.

The child then stopped treatment and was not seen again until January, 1931, at which time he had perfect motion and function, and no deformity.

He was seen again, Sept. 30, 1931; the result was perfect, anatomically and functionally. He was 10 years of age and in this period of two and a half years had developed through bone transformation and functional use a practically normal arm.

### COMMENT

This case represents not a standard nor even a generally accepted method of treatment but represents the best judgment of two surgeons in an attempt to prevent the development of an almost certain Volkmann's ischemic paralysis.

In the prevention of it there was a successful outcome; we were not so sure as to the fracture. Time, however, proved that growth and function could do great things. Throughout the conduct of this case, we had the hearty and interested cooperation of the parents, and they were at all times prepared to have the child operated on, but at each visit we delayed until the "next time." The end-result justified the means.

321 Dartmouth Street.

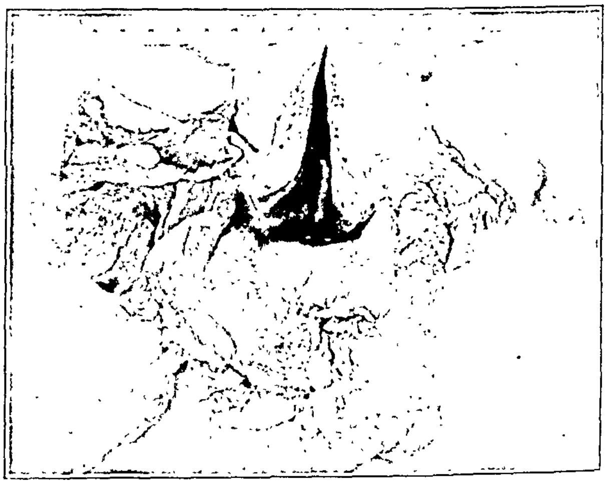
## THE CERVICAL PESSARY—A MENACE TO HEALTH AND LIFE

Harold O. Jones, M.D., Chicago

The widespread use of different types of cervical pessaries, presumably for therapeutic purposes but in reality for contraception, prompts this report. Physicians are led to believe that these instruments are beneficial to patients suffering with dysmenorrhea, or at least that they are harmless. Both assumptions are false. Within the last few years more than a dozen patients have been seen in the gynecologic service at St. Luke's Hospital with severe pelvic peritonitis and cellulitis due to infections originating about these pessaries. The following is an illustrative case history:



Pessary in place.

Mrs. M. R. entered St. Luke's Hospital in the service of Drs. Harry E. Mock and N. C. Gilbert too ill to permit either a complete history or a satisfactory examination. The clinical diagnosis was miliary tuberculosis.

Four months prior to admission, a cervical stem pessary had been inserted. Less than forty hours after admission, the patient died. Postmortem examination revealed a yellow metal pessary in the uterus; acute ulcerative endocarditis and ulcerative endocervicitis; thrombo-ulcerative endocarditis of the right auricle and the thebesian valve; mural thrombo-ulcerative endocarditis of the left ventricle; local fatty changes of the myocardium, and changes such as are usually seen with septicemia.

Cultures of the blood from the heart and from the uterus yielded Streptococcus hemolyticus.

The accompanying illustration shows the pessary in place.

104 South Michigan Avenue.

**Psychology.**—It is an astonishing fact that in most countries medical courses boast no classes in psychology. Though no one seriously disputes the need of knowledge of psychology, the student is left to his own devices to secure such understanding, when, how and as he may.—Sigerist, H.: Man and Medicine, New York, W. W. Norton & Co., Inc., 1932.

## *Special Article*

# THE RELATIONSHIP OF THE PRIVATE MEDICAL PRACTITIONER TO PREVENTIVE MEDICINE

Sir ARTHUR NEWSHOLME, M.D., F.R.C.P., K.C.B.
BIRMINGHAM, ENGLAND

My duty here is to outline briefly developments and changes during recent decades, in Europe generally and particularly in Britain, in preventive as related to clinical medicine, and the influence of this altered orientation on the work of the private medical practitioner.

I may claim some advantage in discussing this subject; for not only did I engage in general medical practice during several years of my earlier professional life, but also for over thirty-five years I held responsible positions in public health work in England; and more recently I have during several years had opportunities to observe forward movements in America, and for the last three years have been completely occupied in a special study of the problem throughout Europe.[1]

My simplest plan would be merely to outline the main movements in Europe, leaving the reader—as I must in the end—to determine how far and in what respects, if any, European experience may be applicable to the circumstances of American life. To give this outline is my main task; but my sketch of European developments will, I am convinced, be more useful if prefaced by a few postulates, most of which will command unalloyed approval. These postulates, if accepted, will help in the judicial weighing and measuring of European developments. I am not without hope that some, at least, of these postulates will be considered worthy to rank as axioms.

My first postulate is that

> 1. Neither instructed public opinion nor the medical conscience, which in this connection is the advance-guard of Christian civilization, can tolerate the continuance of neglected sickness.

Several corollaries, or interdependent postulates, follow from this first postulate:

> 2. Medical care in its widest sense must be made available for all, as an important element in securing maximum efficiency and happiness in a civilized community.

Neglect to provide medical care for every member of the community being repulsive to the medical even more than to the public conscience, it follows that

> 3. Gaps and imperfections in present medical services must be made good and medical care must be of a quality which does not lack in any essential respect all that is necessary for expeditious recovery or for comfort, if recovery is unattainable.

It will be agreed that there can be no difference of opinion as to the preceding postulates. Controversy arises only when plans and methods are discussed, which necessarily are governed by financial as well as by medical considerations.

It is unnecessary for me to argue the truth of the further postulate that

> 4. Health is worth whatever expenditure is efficiently incurred in its maintenance or to secure its return.

I will therefore proceed at once to the postulate that

> 5. In present circumstances, both in America and in Europe, adequate scientific medical service has become unattainable by isolated or family effort standing alone, for a high proportion *of the total population.*

The evidence in favor of this statement is given in "Medicine and the State"; its truth is beyond dispute.

In passing, it is well to remember that there is a corresponding dependence on extrafamilial aid in our own training for the medical profession. In Britain, and I assume also in America, a large share of the cost of medical education is borne by state endowments or by gifts and endowments from the beneficent rich. It may be said, then, that neither doctors nor their patients are completely independent of communal financial aid, supplementing family resources.

The last postulate leads to the next:

> 6. For a large portion of the total sick population measures must be, and in part are already, organized to assist in providing necessary medical services, the sources available being private charity, communal taxation, and provident insurance for future needs.

In Europe these three sources, or two of them, are often seen in combination.

The need for special medical services (laboratory, physical diagnosis, specialist clinical departments) is an outstanding feature of modern medicine. While we welcome these aids to good work—for the rapid development of which general medical practitioners, in their wish to do the utmost for their patients, are largely responsible—I desire to add a further postulate as follows:

> 7. There is need to organize such cooperative work as will secure that specialism, which necessarily is concerned mainly with the disease, is not allowed to submerge the wider and wiser outlook of the general practitioner who is concerned with the patient himself.

Modern medicine calls for a further postulate, demanding a wider investigation of his patient than the private practitioner and specialist often give:

> 8. There is often needed a study of the patient from a psychic, social, economic and occupational standpoint, if his illness is to be accurately diagnosed and satisfactorily treated.

In view of this desideratum it is not surprising that social agencies and public authorities have taken a hand in medicine; and here again, as in the parallel case of experts and private practitioners, we still need to discover and to apply the best concerted methods of social team work.

---

[1] The results of this investigation are given in my "International Studies on the Relation Between the Private and the Official Practice of Medicine": vol. I. Netherlands, Denmark, Sweden, Norway, Germany, Austria; vol. II. Belgium, France, Italy, Jugoslavia, Hungary, Poland, Czechoslovakia; vol. III. Great Britain and Ireland; and a more general statement in "Medicine and the State," Baltimore, Williams & Wilkins Company, 1932.

One further postulate is now generally accepted:

9. Modern medicine is becoming increasingly physiological and decreasingly pathological

—an effort on the part of the physician to aid in securing and maintaining maximum psychophysical efficiency, not merely or only efforts to regain it when damaged or lost. This change necessitates the searching out of early departures from health, and the giving of counsel in health which if adopted will diminish or prevent their occurrence.

At this point an almost parenthetical remark may be made on periodic medical examinations, the advocacy of which has become an accepted policy of the medical profession. In my view these examinations should usually form part of a medical overhaul of every member of a family by the family doctor, the findings to be reviewed at intervals. I have never disguised my opinion that periodic examinations of men, say between 40 and 60—though the advice based on such examinations is useful and may retard illness—are too late as regards the most serious causes of breakdown in this middle period of life, and that the earlier family care predicated above has an immensely wider scope of preventive potentiality. It is at earlier ages that the chief sources of permanent middle-life breakdown originate. In childhood and youth occur the septic diseases and acute infections, including acute rheumatism, which produce cardiac and other disablements in middle life; at the same period of life or in early adult life tuberculosis causes a serious though decreasing drain on life; while the syphilitic virus, usually inoculated in early adult life, produces its results in arterial degeneration, premature old age and insanity perhaps some twenty years later.

These three greatest sources of permanent disablement and death during the working years of life can best be obviated by the application of clinical and social medicine during childhood, youth and adolescence. But, let me add, I do not doubt that later medical overhauls have some preventive value, and a greater value in staying the progress of disease already present.

### PUBLIC AUTHORITIES AND MEDICINE

With the preceding postulates in mind, let us next glance at European developments in the relationship between the public and the private practice of medicine. Public authorities for long have busied themselves with the medical care of the sick poor (and of maternity) both domiciliary and in hospitals. In other directions their incursions into medicine have been more recent and have been activated chiefly by the growth of preventive medicine and public health.

*Medical Aid for the Poor.*—In all European countries there is some provision of medical aid for the necessitous, including help in childbirth. It may take the form of a special medical officer in every district for this work, as in Britain and the Scandinavian countries; or, as in France, every doctor may undertake this work according to a fixed schedule of fees. The French system is being advocated in Britain by the British Medical Association. This medical service for the poor includes also institutional medical treatment, now greatly improved in quality in Britain. In Ireland, in many, especially in rural, districts, half the population receive gratuitous medical service; and it may be said that Ireland approaches nearest of all countries known to me to a state medical service, the cost of which falls on general taxation. Its medical officers are not precluded from private practice.

In Scotland there is a special state service for its Highlands and Islands, in which, otherwise, medical aid would be lacking. The government guarantees the salaries of doctors in supplementation of fees paid by patients, and gives mileage allowances for traveling. Local needs in this important development have impelled governmental action at the expense of the national taxpayer. Is not such action indicated in certain mountainous parts of the Southern states in America, especially for midwifery and for that terrible disease trachoma? Not even the most rigid opponent of state intervention can doubt its necessity in areas where otherwise our three first postulates cannot be met.

This is the case of utmost need; but, short of this, nearly every private medical practitioner, especially in rural districts, day by day is himself a vicarious substitute for the state, for he gives medical aid gratuitously—as every member of the medical fraternity in conscience must—when need arises. He resembles the tax gatherer—except that much medical work is gratuitous—in that he charges his patients not according to their needs but according to their means; and as in the case of taxation it is payments by the well-to-do which enable him to attend his poorer patients gratuitously or at a charge which does not cover expenses. Thus the private doctor, the tax gatherer and the medical official alike are state servants, but the state service of the first of these is unacknowledged.

*Hospital Provision for the Poor.*—Hospitals in the first instance were an output of Christian charity, their full medical utility developing very slowly. In nearly every country hospitals are now the chief centers of medical work and of the research in medicine which is indispensable for progress. In Britain, voluntary hospitals, provided by the gifts and bequests of the charitable, still hold their premier position. But in recent decades public authorities in every country have been active in providing hospitals, and in continental Europe the hospitals of these authorities have almost completely replaced voluntary hospitals. In Britain, voluntary hospitals have held their ground, but they have not met the rapidly increasing needs of the public, and now official hospital beds—even when the beds in mental hospitals are excluded—largely exceed in number the beds in voluntary hospitals.

Private practitioners, as they will agree, are largely responsible for this great increase of treatment in hospitals, through their scrupulous desire to secure for their patients the full advantage of special skill in medicine and surgery.

In continental countries, payments are exacted from hospital patients according to their means, the payments for insured patients being made in part by the insurance societies to which the patients belong. In England very rapidly there is growing up a voluntary system of partial insurance for hospital treatment, independent of the compulsory national sickness insurance scheme, for about a third of the total population. For a weekly payment of perhaps three pence, employers sometimes contributing an equal amount, families are partially insured for consultative services and when necessary for treatment in hospitals. In some towns, half the cost of maintenance of voluntary hospitals is now derived from this and allied sources.[2]

---

[2] See page 95 of my "Medicine and the State" for details.

Evidently such a system lends itself to increasing abstractions from private medical practice; and although the majority of these patients would be sent to a hospital by the medical practitioner treating them, there are others who should remain under his care. This needs to be more strictly regulated. In countries in which national sickness insurance schemes are in operation (Germany and Austria, Hungary, Poland) there has occurred an immense development of hospital and polyclinic (ambulatorium) work which greatly needs to be coordinated and regulated, owing to its independence of the work of the general practitioner.

Outside Britain, national insurance schemes include some hospital treatment, but continental insurance organization can seldom pay more than half the cost, and in all countries hospital charges are paid largely, sometimes completely, by general taxation. The arrangements in Britain have already been indicated.

The foregoing is a brief outline of the position reached in what, for lack of a better term, I must call socialization[3] of the medical services, domiciliary and institutional, for the absolutely necessitous, the poor, and for that large part of the total population who are not far above the poverty line.

Is clinical medicine preventive medicine? At this stage the criticism will suggest itself that my remarks do not relate to preventive medicine. But if, as I claim, medicine is preventive when it curtails illness, when it decreases suffering, when by treatment (e. g., of an operation for cancer, or the radical cure of hernia or varicose veins) it restores a patient to the rank of self-supporting citizens, or when, for instance, in the scientifically regulated administration of insulin, it gives many added years of useful life, then surely clinical medicine is preventive medicine in a real sense.

If this be admitted, then we must regard all efficient clinical medicine as also an important branch of preventive medicine. But we are especially concerned with new developments of clinical medicine having direct and obvious bearing on public health, and to these we must now direct our attention.

1. *Free Hospitals for Infectious Diseases.*—In its earlier development, public health was fairly distinct from clinical medicine in most particulars, but never completely so; for even in the course of the earlier dramatic triumphs won by sanitation, the necessity arose also of treating cholera patients and of treating and segregating cases of "fever" and smallpox. Now in nearly every country some hospital provision for the chief infectious diseases is provided gratuitously. Thus, for the isolation and treatment of the infectious sick the socialization of medicine has become almost complete.

2. *Free Immunization.*—A step beyond this has been taken. Public medical vaccinators are provided in most countries for gratuitous vaccination against smallpox. In rural districts in Norway, specially trained midwives do some of this work.

More recently a large amount of immunization against diphtheria has been done at the public expense, especially in America. In America this may be done also by private practitioners to whom public authorities supply the necessary toxoid-antitoxin at the public expense, and whose officers may give demonstrations of the method to be employed. My own view is that, subject to strict regulations as to methods,[4] private practitioners should be entrusted with this work for both smallpox and diphtheria, and paid for it by public authorities at a fixed charge irrespective of the social position of patients. Under such a system we should, I think, secure a much more widely protected population than at present.

3. *Free Ancillary Services.*—The provision by public authorities of ancillary aids to diagnosis is another development of socialized medicine of great importance. In the initiation of laboratory facilities for the diagnosis of diphtheria and tuberculosis, American pioneers, Biggs, Prudden and Park, have led the way.

The extensions of such work, including sometimes free examination of tumor specimens and of blood counts, and on the physical side x-ray photographs in tuberculosis, are well known. In every country these state-paid arrangements exist more or less fully developed. Here, then, is a further instance of the socialization of a branch of medicine, which, although it belongs to clinical medicine, is equally important in preventive medicine. One cannot easily exaggerate the value of the aid thus given not only to the doctor and his patient but also to preventive medicine, when adequately utilized by the medical practitioner in his daily work.

But public health authorities have not confined their activities to communicable diseases.

4. *Treatment of Non-infectious Diseases.*—I have already claimed clinical medicine as a branch of preventive medicine, in a large part of its activities. Let me take as a further example that of the institutional treatment of cripples. Local authorities in Britain on a large scale now treat institutionally cases of hip disease, extreme rickets, or the deformities following poliomyelitis, and thus, partially or entirely at the public expense, restore many children to useful life.

5. *The Care of Maternity.*—To a very exceptional extent—though in continental Europe a vast amount of public aid is given in maternity—the care of maternity has become in England a subject of wide action by public authorities. Midwives, who attend 60 per cent of total confinements, are strictly supervised and regulated by these authorities. They are obliged to call in medical aid in emergencies. The doctor called in is chosen by the patient, and the local authority is legally required to pay the doctor's fee on a fixed scale. The local authority recovers this fee from the patient or her husband, or part of it, when possible. Local authorities also provide lying-in hospitals for poorer women, treatment in which is given at low charges, sometimes remitted. They also provide antenatal consultation centers, the relation of which to the work of general practitioners is not yet thoroughly adjusted.

Returning to communicable diseases, tuberculosis and venereal diseases are two of the chief scourges of mankind, accounting probably for a fifth part of total deaths from all causes; and it is to combat these diseases that public authorities have entered most extensively into clinical medicine as an agent of public health.

6. *Control of Tuberculosis.*—Work for the control of tuberculosis in Europe is like that in America. Free bacteriologic examination of sputum is provided, still too often neglected by some private practitioners. Then the reporting or notification of cases of tuberculosis is

---

[3] The word "socialization" is employed here to denote medical service given at the expense of the state (through taxation) or of a voluntary organization (through gifts), the patient not paying except so far as he may have been a taxpayer or a donor to the voluntary charity. If he pays in part, to this extent his position is changed.

[4] Strict regulations are called for to insure uniformly efficient work and to minimize the appreciable risks of septic complications.

required as soon as the practitioner has made his diagnosis; and here also one must bemoan that the fulfilment of this duty is often neglected and oftener seriously delayed.

The general measures taken are well known, and I need not particularize except to say that in all European countries the institutional treatment of tuberculosis is undertaken by public authorities, chiefly at the expense of the taxpayer. In continental Europe much of this cost is borne by sickness insurance funds, but in Britain it falls entirely on the public authorities. The position is accepted and acceptable to most practitioners. The fact that one third of the total population of Britain is insured under the national insurance scheme, and that the treatment by public authorities lifts some burden from the practitioner's shoulder, without implying any reduction of his per capita payments, is a factor in the position.

7. *The Treatment of Venereal Diseases.*—In most European countries, some treatment of venereal diseases is undertaken at the public expense. In several European countries (Austria, Italy, Denmark, Sweden and Britain), gratuitous treatment is undertaken by public authorities without restrictions. In Belgium, free medicaments are supplied to doctors, and great stress is laid on securing the cooperation of private practitioners. In Britain, private doctors have come to regard these diseases as needing specialist treatment, and I have often been informed by them that they thankfully pass on their cases of these diseases to the clinics of the public authority. A minority of doctors continue to treat their own patients, and arsphenamine is supplied free to these doctors.

The position in Britain has become one of almost complete socialization of the treatment of venereal diseases at the expense of the public purse. Clinics (usually attached to voluntary hospitals, that is, hospitals not supported by taxation) are provided in all considerable centers of population; and patients are treated at these (in hospital beds when necessary) gratuitously without any residential restriction and with entire disregard of financial position. Pathologic examinations (for gonococci and Wassermann tests) are also undertaken gratuitously for all practitioners.

A tribute must be paid to the attitude of the British Medical Association in this matter, as representing the mass of medical opinion. When the report of the Royal Commission on Venereal Diseases was published in 1916, and the government promptly made its national proposals, these were sent in draft to the council of the association; and in its reply the association, while realizing that they embodied "a new departure of a most important kind," resolved in general approval of these proposals that

> measures for the best modern treatment of venereal diseases should be readily available for the whole community, and that arrangements made should be such that persons affected by these diseases will have no hesitation in taking advantage of the facilities for treatment that are afforded.

It further resolved that

> the treatment at any institution included in a local authority's scheme should be free for all. There should be no refusal to treat a patient who is unwilling to go to his own doctor.

In its report on this subject, the council of the association made the following comment, subsequently endorsed by the representative meeting of the association.

> The policy of the association in connection with treatment at hospitals has always been that persons who are able to pay for their own treatment should not be treated at charitable institutions except in emergency, but should be referred to a private practitioner. In endorsing the recommendation of the Royal Commission the Council recognizes the exceptional nature of venereal disease; the reluctance of patients affected by them to go to their private medical attendant; the risk that they may go to unqualified persons for treatment with disastrous results to themselves and to others; and the importance to the community of adopting all possible measures for inducing sufferers from venereal disease to seek early and adequate treatment. On these grounds the Council is of opinion that the recommendations of the Royal Commission should be accepted and approved by the association.

As I was a member of the royal commission whose recommendations were thus endorsed, and as I was officially responsible for formulating and organizing the measures to give them effect, it is pleasant once more now to testify to the public-spirited action of the general medical profession in Britain as voiced by their association. At the present time unrestricted gratuitous venereal disease clinics are available everywhere, and the reduction in the amount of one of our chief social cankers has justified the action of the government and the medical profession's endorsement of this action.

8. *The Searching out of Disease.*—Public authorities have not been contented with sharing in the cost of treatment of a certain number of diseases at the expense of the communal purse. In recent decades a most striking development has occurred, as the result of increasing realization that delayed treatment of the sick implies a lowered prospect of recovery and protraction of inability to work; and more and more it is being realized that the ideal for the medical practitioner is not merely to treat patients who apply to him but to enter into an arrangement with the families entrusted to his care, which will enable him, without suspicion as to his conduct being altruistic, to strive to discover disease hitherto undetected and to prevent its continuance. This means an important development in preventive medicine. Payment according to the number of "medical acts" has discouraged development in this important direction; and until the circumstances of family remuneration are altered, most practitioners in all countries remain relatively helpless except for their insured patients. Meanwhile several of the postulates already stated are being partially neglected; and until or unless this neglect ceases, we cannot as private practitioners of medicine complain if public authorities "get busy." As a medical confraternity it is our business to make public activities at least partially superfluous.

9. *School Medical Service.*—This point is best illustrated in the findings of school medical inspectors. Without detailing the important work under this heading in many European countries, it may be said that in all of them some official treatment of defects and diseases found in school children is being effected, though, as a rule, parents are encouraged in the first instance to employ their own doctors. We cannot reasonably object, either, to the inspection or the medical treatment of school children at school clinics, unless as private practitioners we are able to organize arrangements which are equally good and complete for every child attending school whose parents are able and willing to pay. Even then children will remain for whom public treatment must be provided.

In continental Europe the amount of medical work needing to be done by educational authorities is less than that in Britain, because in the former dependents come within the scope of the treatment given under national sickness insurance schemes. In Britain also—except for the minor conditions for which parents seldom have a doctor—the treatment undertaken in school clinics is chiefly specialist in character (e. g., ringworm, ophthalmic tests, treatment of adenoids and deformities, dental treatment) and for most pupils this specialist treatment must be carried out either at hospitals or in special school clinics. It should be added that the morbid conditions found by school medical inspectors commonly are the late results of long-established disease (otorrhea, advanced dental caries, deformities) or of malnutrition; but although these ought often to have been discovered some years earlier, their neglect would, but for the school service, have been still further prolonged.

We have, then, in the medical inspection of schools and the resultant action a further instance of socialization of medicine, having as its object the discovery and treatment of neglected illness. It is a form of socialized medicine which might, to a very considerable extent, be replaced by cooperative team work by private medical practitioners. It is socially desirable that they should in fact arrange to take up this much neglected work and thus secure the fulfilment of the postulates already stated, either alone or with supplementary aid from public agencies.

10. *Treatment to Anticipate Disease.*—We come last to the greatest advance made in medicine, an advance shared in varying proportions between public authorities and the most far-seeing of private medical practitioners. This consists in action which, constituting, as it does, anticipatory treatment, prevents the occurrence of illness and defects. In this direction lie the chief future triumphs of medicine, and it is for private practitioners themselves to determine whether this work shall remain largely the domain of public authorities and social organizations or whether private practitioners shall carry out this work for every family in their care. To do this work, general practitioners will need to pool some of their activities, to employ jointly not only sick-bed nurses but also public health nurses (health visitors) to undertake much quasi-medical work, which is too costly when done by doctors and cannot be expected from them, though they should guide and direct it. On these lines, rickets will soon disappear; more favorable growth and development will be promoted, and the general standard of health will be raised through improved nutrition and general hygiene. The promotion of the psychic health of children forms an important part of a complete program in this direction, which the medical practitioner must recognize, even though his share in this work is chiefly indirect.

Meanwhile in every European country public authorities and voluntary agencies are busy with this most important of preventive work; while private practitioners who might be in charge of much of it, singly and cooperatively, have little concern with it, under present conditions of medical practice. The program here indicated cannot wait; hygienists and their organizations will not wait; educated public opinion will not wait; cannot we hope that private practitioners will make it a chief part of their future work?

11. *Insurance Treatment.*—In the preceding very rudimentary outline of my subject, I have only incidentally mentioned the great sickness insurance systems which are now established in most European countries. They have not hitherto conduced much to preventive medicine, except so far as treatment of disease tends to prevent its prolongation, to reduce its severity or to prevent its recurrence. I do not doubt that under highly satisfactory organization the medical care in sickness insurance can be made valuable as an instrument of preventive medicine; though this will be difficult. The difficulty in securing this end is undoubtedly increased by the fact that monetary benefits depend on medical certification; for a scheme of insurance for domiciliary medical care without money benefits during disablement has not, so far as I know, been adopted on a very large scale in any country. Even with the handicap constituted by combining insurance for medical and for monetary benefits, the cause of preventive medicine can be satisfactorily served if we secure almost superhuman competence in the management of the insurance scheme, and that the scheme furthermore is adhered to by every insured person and every doctor with almost superhuman loyalty and integrity.

I have already indicated my view that for a large section of the population a complete medical service necessitates contributions from the persons benefited on an insurance plan, and that even then some aid from the state is necessary. The only practical alternative consists in vast extensions of state service without insurance.

Under an insurance service, hospital and consultative services can be brought within the reach of all; and doctors by pooled effort can similarly supply a domiciliary service which will be satisfactory both to them and to their patients. Additional communal help would be needed for the poor.

I agree that money benefits during disabling sickness are a great boon, even though the medical problem is much more difficult when combined with the financial problem. The lot of the doctor who has to hand out certificates which authorize money allowances is not altogether happy, and the withholding of such certificates is often an obnoxious task. But it may need to be faced, especially so if—and this appears to me to be the position throughout Europe—the practical alternative is a medical system in which doctors would be, and their patients would be paid for, in the same way as are our state school teachers and the pupils under their charge in our system of national free elementary education.

But even the defects of existent sickness insurance systems should not loom too large in our minds. Furthermore, defects in other branches of public medicine and in private practice alike only partially obscure the great advances and improvement both in private and in public medicine of the last thirty years. Ignorance will continue, though it will grow less; the immeasurably more serious defects of character will also continue, in connection both with public and with private medicine; but they will, I am confident, decrease, and we can look forward to a higher standard of medical work and a more complete utilization of the invaluable aid which medicine practised in a cooperative spirit can give to humanity. But vigilance and altruistic effort will always be needed on whatever detailed lines increased utilization of medical skill develops and extends.

> Does the road wind uphill all the way?
> Yes, to the very end, my friend.

# Council on Pharmacy and Chemistry

## NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

**CHAPPEL LIVER EXTRACT (SUBCUTANEOUS).**—A sterile aqueous solution, containing the nitrogenous, nonprotein fraction G of Cohn et al. obtained from fresh mammalian liver, preserved with cresol 0.4 per cent. Each cubic centimeter contains the active material extracted from 10 Gm. of liver.

*Actions and Uses.*—Chappel liver extract (subcutaneous) is proposed for subcutaneous or intramuscular injection in the treatment of pernicious anemia.

*Dosage.*—Two cc. daily; the maintenance dose is 2 cc. daily at intervals of from ten to twenty days.

Manufactured by Chappel Bros., Inc., Rockford, Ill. No U. S. patent or trademark.

*Ampoules Chappel Liver Extract (Subcutaneous) 2.5 cc.:* Each cubic centimeter contains the active material extracted from 10 Gm. of liver.

To prepare Chappel liver extract (subcutaneous), finely ground equine livers are extracted several times with water. After precipitation of the proteins by heat, the liquid is concentrated in vacuo at low temperature, alcohol added to bring the alcoholic strength to 70 per cent, the precipitate filtered out, and the filtrate again evaporated. Sufficient absolute alcohol is then added to bring the alcoholic strength of the liquid up to 95 per cent. The precipitate is then dissolved in water and the reaction of the solution adjusted to $p_H$ 7.2. Each cubic centimeter of the finished product represents the active material from 10 Gm. of liver. Cresol 0.4 per cent is added as preservative and the solution is then filtered.

**ALLERGENIC EXTRACTS-LEDERLE.**—Liquids obtained by extracting the protein of substances believed to be the cause of specific sensitization.

*Actions and Uses.*—See Allergic Protein Preparations, New and Nonofficial Remedies, 1931, p. 24.

*Dosage.*—See Allergic Protein Preparations, New and Nonofficial Remedies, 1931, p. 24.

Allergenic Extracts-Lederle are marketed in 6 cc. vials.

Manufactured by the Lederle Laboratories, Inc., Pearl River, N. Y. No U. S. patent or trademark.

Undiluted and 1:10 Dilution: *Banana Allergenic Extract-Lederle,*[5] *Beef Allergenic Extract-Lederle,*[3] *Chicken Meat Allergenic Extract-Lederle,*[3] *Codfish Allergenic Extract-Lederle,*[3] *Cornmeal Allergenic Extract-Lederle,*[2] *Crabmeat Allergenic Extract-Lederle,*[3] *Green Pea Allergenic Extract-Lederle,*[2] *Horse Serum Allergenic Extract-Lederle,*[6] *Lamb Allergenic Extract-Lederle,*[3] *Lima Bean Allergenic Extract-Lederle,*[2] *Milk Allergenic Extract-Lederle,*[6] *Orange Allergenic Extract-Lederle,*[5] *Pork Allergenic Extract-Lederle,*[3] *Pyrethrum Allergenic Extract-Lederle,*[7] *Rice Allergenic Extract-Lederle,*[2] *Rye Allergenic Extract-Lederle,*[2] *Spinach Allergenic Extract-Lederle,*[5] *Tobacco Allergenic Extract-Lederle,*[7] *Wheat Allergenic Extract-Lederle,*[2] *White Potato Allergenic Extract-Lederle.*[5] Undiluted, 1:10 dilution, and 1:100 dilution: *Horse Serum Allergenic Extract-Lederle,*[6] 0.5 mg. of nitrogen per cc. and 0.05 mg. of nitrogen per cc.: *Chocolate Allergenic Extract-Lederle.*[8] 0.2 mg. of nitrogen per cc. and 0.1 mg. of nitrogen per cc.: *Sheep Dander Allergenic Extract-Lederle.*[4] 0.2, 0.1, 0.01, and 0.001 mg. of nitrogen per cc.: *Horse Dander Allergenic Extract-Lederle,*[4] *Orris Allergenic Extract-Lederle.*[7] 0.2 and 0.01 mg. of nitrogen per cc.: *Cow Dander Allergenic Extract-Lederle,*[4] *Flaxseed Allergenic Extract-Lederle.*[1] 0.2 and 0.001 mg. of nitrogen per cc.: *Cottonseed Allergenic Extract-Lederle.*[1] 0.1 mg. of nitrogen per cc: *Feathers Allergenic Extract-Lederle,*[4] *Goat Dander Allergenic Extract-Lederle.*[4] 0.1 and 0.01 mg. of nitrogen per cc.: *Buckwheat Allergenic Extract-Lederle.*[2] 0.1 and 0.005 mg. of nitrogen per cc.: *Almond Allergenic Extract-Lederle,*[1] *Peanut Allergenic Extract-Lederle.*[1] 0.1 and 0.001 mg. of nitrogen per cc.: *Dog Dander Allergenic Extract-Lederle,*[4] *Egg White Allergenic Extract-Lederle,*[6] *Kapok Allergenic Extract-Lederle,*[1] *Mustard Allergenic Extract-Lederle.*[9] 0.05 and 0.001 mg. of nitrogen per cc.: *Cat Dander Allergenic Extract-Lederle,*[4] *Rabbit Dander Allergenic Extract-Lederle.*[4]

Allergenic extracts-Lederle are prepared from various substances by extraction with a buffered saline solution composed of sodium chloride 0.5 Gm., potassium dihydrogen phosphate ($KH_2PO_4$) 0.0363 Gm., sodium phosphate ($Na_2HPO_4.12H_2O$) 0.1431 Gm., Phenol 0.4 Gm., distilled water to make 100 cc.

Products marked 1 are prepared by the following method: The material is shelled and ground, treated with toluene, alcohol and ether. The dry and oil-free flour is extracted with the buffered solution. The extract is dialyzed and sterilized by filtration.

Products marked 2 are prepared by the following method: The powdered whole grains are washed with toluene, alcohol and ether. The buffered saline extract of the defatted flour is dialyzed, concentrated and sterilized by filtration.

Products marked 3 are prepared by the following method: The ground material is treated with toluene and then placed immediately in the buffered extracting fluid. The extract is dialyzed and sterilized by filtration.

Products marked 4 are prepared by the following method: The material is ground in a mortar and washed with ether and alcohol. The dry residue is extracted with buffered extracting fluid. The dialyzed extract is concentrated and the amount of nitrogen per cubic centimeter of the filtered extract is determined by the Kjeldahl method.

Products marked 5 are prepared by the following method: The material is prepared by dialyzing the pressed juice at once against the buffered solution diluted (1-2) until nonirritating to normal skins. The dialyzed extract is concentrated and sterilized by filtration. If the ground material contains very little juice, it is mixed with the extracting fluid and the pressed extract is handled the same, as an original juice.

*Products marked 6 are prepared by the following method:* These extracts are merely dilutions of the original substance in the buffered saline solution. Milk is decaseinated with rennin. The whey is dialyzed against a slightly alkaline buffered solution, concentrated and sterilized by filtration.

Products marked 7 are prepared by the following method: The powdered material is washed with toluene, alcohol and ether. The buffered saline extract of the defatted flour is dialyzed, concentrated and sterilized by filtration. The alcohol-ether treatment is exhaustive and the dialysis continued for a long time in order to insure stability of the extract and complete removal of toxic fractions present.

The product marked 8 is prepared by the following method: Raw unroasted cacao beans are ground and treated with toluene and ether until practically oil free. The resulting powder is extracted with the buffered solution. The extract is sterilized by filtration and standardized on the nitrogen basis per cubic centimeter.

The product marked 9 is prepared by the following method: The powdered material is washed with toluene, alcohol and ether. After evaporation of the fat solvent, it is extracted with the buffered solution. The extract is dialyzed until skin tests prove it to be no longer irritating. The final product is sterilized by filtration and standardized on the basis of its nitrogen content per cubic centimeter.

**DIGALEN-ROCHE (CLOETTA)** (See New and Nonofficial Remedies, 1931, p. 136).

The following dosage form has been accepted:

*Digalen Injectable-Roche:* Ampules containing 2.1 cc. Each 2 cc. represents 1 cat unit, in 8 per cent alcohol.

*Dosage.*—The average dose of digalen injectable-Roche is 2 cc.

**BRUCELLA MELITENSIS VACCINE** (See The Journal, Feb. 6, 1932, p. 480).

The National Drug Co., Philadelphia.

*Undulant Fever Vaccine.*—A heat killed suspension of Brucella melitensis organisms (2,000 million per cubic centimeter) preserved with 0.4 per cent of cresol. The usual sterility tests prescribed by the U. S. government are made, and in addition blood agar streaks are made of the heat killed stock vaccine before the addition of the cresol. Safety tests are made on the stock vaccine by injecting guinea-pigs with the maximum human dose, 1 cc. No potency tests are made. Purity of cultures is determined by the study of colony formation, carbohydrate reactions, and agglutination test with specific serum. The product is marketed in packages of one 5 cc. vial, in packages of one 15 cc. vial, and in packages of one 30 cc. vial.

*Dosage.*—The subcutaneous injection at seven to ten day intervals of doses of 0.25 cc., 0.5 cc. and 1 cc., respectively, is recommended.

## REPORTS OF THE COUNCIL

The Council has authorized publication of the following reports.

W. A. Puckner, Secretary.

### BACILLUS ACIDOPHILUS MILK-HERMES OMITTED FROM N. N. R.

Bacillus Acidophilus Milk-Hermes (Hermes-Groves Dairy Co., Pittsburgh, Pa.) is a whole milk cultured with B. acidophilus. It was accepted for New and Nonofficial Remedies by the Council in 1928. Since the period for which it was accepted would expire at the close of 1931, the firm was asked in June of that year to submit the current labels and advertising for the product in order that the Council might pass on its eligibility for continued inclusion in New and Nonofficial Remedies. The firm did not reply to the report and failed to reply to a second letter. Since noncompliance of a manufacturer with the request for this material deprives the Council of the means of judging the eligibility of the product for continued acceptance, the Council voted to omit Bacillus Acidophilus Milk-Hermes from New and Nonofficial Remedies, 1932.

### IODYL NOT ACCEPTABLE FOR N. N. R.

Under the name Iodyl, the Vel Company, Long Island City, New York, markets a preparation stated to be "an Iodine Dusting Powder containing approximately .69% resublimed iodine and 99.31% of pure boric acid." On the label and in the advertising the iodine content is declared, but the identity and amount of boric acid is not declared on the label, and in the advertising the presence of boric acid but not the amount is declared. The preparation is proposed for use in the treatment of chronic suppurative otitis and in nasal sinuses.

The Council declared Iodyl unacceptable for New and Nonofficial Remedies because a proprietary name for a simple unoriginal mixture of iodine and boric acid cannot be recognized and because the use of a mixture of iodine and boric acid in fixed proportions is not in the interest of rational therapeutics.

# Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## VAN CAMP'S PURÉED GREEN BEANS

*Manufacturer.*—The Van Camp Packing Company, Inc., Indianapolis.

*Description.*—Puréed green beans slightly seasoned with salt, retaining in large measure the original vitamin and mineral content of the raw beans used; packed in enamel lined tins.

*Manufacture.*—Fresh, crisp green beans of choice quality are carefully inspected and any imperfect or discolored ones eliminated. The selected beans are washed in a cylinder equipped with high pressure sprays of water. Following this they are given a short blanch in boiling water, immediately removed from the water, and pressure cooked in an atmosphere of steam. The cooked beans are puréed in an atmosphere of water vapor by being forced through a screen the openings of which are of such size as to produce the desired fineness and texture in the final product. Highly fibrous portions of the beans are discharged from the end of the screen and are discarded. The puréed material is adjusted with hot water to the desired consistency, slightly seasoned with salt, heated, and immediately filled into enamel lined tins, which are sealed and heat processed.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 92.0 |
| Total solids | 8.0 |
| Ash | 1.2 |
| Salt (NaCl) | 0.6 |
| Fat (ether extract) | 0.2 |
| Protein (N × 6.25) | 1.4 |
| Sucrose (copper reduction method) | 2.0 |
| Reducing sugars as dextrose | 0.4 |
| Crude fiber | 0.9 |
| Total carbohydrates other than crude fiber (by difference) | 4.3 |
| Alkalinity number (cc. of normal acid per gram of ash) | 2.1 |
| *p*H | 5.2 |

*Calorics.*—0:2 per gram; 6 per ounce.

*Vitamins.*—The vitamin content of the raw beans is retained in large measure in the manufacturing process by the use of equipment and procedure which excludes admixture of air; the vegetable material is exposed to steam atmosphere only.

*Claims of Manufacturer.*—The Puréed Green Beans are supplementary to the infant milk diet, and a valuable protective food, having a smooth consistency supplying a desirable bulk without roughness. The puréeing renders the nutrient content readily available for digestion. The product is scientifically prepared to retain in large degree the natural mineral and vitamin values of green beans.

## MORTON'S FREE RUNNING SALT

*Manufacturer.*—Morton Salt Company, Chicago.

*Description.*—A table salt containing 0.7 per cent added magnesium carbonate which tends to preserve its "free running" properties.

*Manufacture.*—The raw salt is obtained by hydraulic mining from underground deposits of rock salt from 250 to 2,300 feet deep by pumping surface water into wells drilled into the salt body. The water with dissolved salt is forced to the ground surface and conveyed to treating and settling tanks, where the brine is chemically treated with small quantities of calcium hydroxide and sodium carbonate for the reduction of natural impurities and is concentrated in "vacuum" pans; the precipitated salt crystals are removed by special mechanical devices. The salt crystals are washed with fresh brine to remove adhering brine containing impurities from the evaporation process. The salt, after washing, is a thick slurry of crystals and brine; excess brine is removed by filtering and the crystals are dehydrated to about 2.5 per cent moisture. The dried salt is further dried at 132-148 C. in rotary kiln driers to 0.1 per cent moisture. The kiln dried salt is mechanically separated into crystals of various granulations. Salt of a definite granulation is mixed with about 0.7 per cent magnesium carbonate, which tends to keep it "free running." The mix is automatically packed in special moisture-resisting cartons and sealed.

An only exception to the foregoing procedure occurs when the crude salt is produced by solar evaporation of sea water, whereby a very coarse large crystal salt is obtained. This crude salt is washed and is dissolved in fresh water, and the brine is handled as described.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 0.10 |
| Calcium carbonate | 0.01 |
| Calcium sulphate | 0.52 |
| Calcium chloride | 0.03 |
| Magnesium chloride | 0.01 |
| Magnesium carbonate | 0.70 |
| Salt (NaCl) | 98.60 |

*Claims of Manufacturer.*—Morton's Free Running Salt is for all table and cooking uses of salt. The added magnesium carbonate tends to preserve its "free running" qualities.

## BROMM'S KEW BEE BREAD

*Manufacturer.*—L. Bromm Baking Company, Inc., Richmond, Va.

*Description.*—A white bread made by the sponge dough method.

*Manufacture.*—The sponge dough ingredients, patent flour of northwest and southwest wheats, water, lard, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, dextrose, lard, powdered skimmed milk, a mixture of calcium acid phosphate and calcium peroxide and potato flour to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms are kept in strictly sanitary condition.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 32.6 |
| Ash | 0.8 |
| Fat (ether extraction method) | 1.2 |
| Protein (N × 6.25) | 9.8 |
| Crude fiber | 0.2 |
| Carbohydrates other than crude fiber (by difference) | 55.4 |

*Calories.*—2.7 per gram; 77 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## CLOVERDALE GINGER ALE (AMBER)

*Manufacturer.*—Cloverdale Spring Company, Baltimore.

*Description.*—A carbonated beverage prepared from Cloverdale Mineral Water, sucrose, citric acid, ginger extract and capsicum; colored with caramel.

*Manufacture.*—The ingredients noted above in definite proportions are dissolved in Cloverdale Mineral Water (The Journal, March 5, 1932, p. 816). The solution is bottled and carbonated as described for Cloverdale Mineral Water.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 90.2 |
| Total solids | 9.8 |
| Ash | 0.01 |
| Protein (N × 6.25) | 0.02 |
| Fat (ether extract) | 0.0 |
| Reducing sugars as dextrose | 0.8 |
| Sucrose (copper reduction method) | 6.3 |
| Titratable acidity as citric acid | 0.09 |
| Caramel color | present |
| Undetermined | 2.6 |
| Flavored with essential oils and essence of ginger | |

*Calories.*—0.3 per gram; 9 per ounce.

*Claims of Manufacturer.*—A bottled, carbonated ginger ale colored with caramel.

## THE "TRACE" ELEMENTS IN THE BODY

Any one who consults the books on physiology of a previous generation will soon discover that they contain only scanty accounts of the inorganic constituents of the body and their possible rôle in nutrition. Considerable stress was placed on the need of common salt (sodium chloride); the occurrence of calcium and phosphorus in the bones was well recognized; iron was associated with the hemoglobin of the blood; and the elements potassium, magnesium and occasionally silicon also received mention. All of these were known to exist both in our foods and in our bodies in readily measurable amounts. The occurrence of "traces" of other elements, notably some of the heavy metals, was reported from time to time; but they were regarded as accidental constituents that had found their way into the organism as chance ingredients of the food or water that was consumed. Biologic importance was rarely assigned to them except when through increasing proportions they suggested the possibility of becoming toxic.

In the Mendel anniversary number of the *Yale Journal of Biology and Medicine*, Mary Swartz Rose[1] has pointed out that during the past ten years we have gradually become accustomed to thinking quantitatively in nutrition, not only in terms of calories and grams of proteins, fats and carbohydrates but also in terms of fractions of milligrams of mineral elements and vitamins. Vitamin A exerts a protective action when present in no higher concentration than 1 part in 2 million in the body of the rat; and the minimum protective dose of vitamin D against rickets is reckoned as no more than one ten-thousandth of a milligram of viosterol. Estimates of the total iodine content of the body scarcely exceed 50 mg. Lunde and Closs have recently estimated the iodine in human blood as from 11 to 16 micrograms per hundred cubic centimeters, and the amount necessary to meet all requirements of metabolism at about 0.05 mg. daily. For prevention of goiter in healthy adults much less may be adequate, since von Fellenberg reports about one third of this amount daily as sufficient for the maintenance of iodine balance in an adult. On this basis the iodine requirement for three years would be no more than the amount of iron required for a single day.

Rose points out that investigation as to the occurrence and function of "trace" elements in both plant and animal life is now active. Boron, zinc and manganese have all been shown essential to the growth of maize; boron, to a great variety of dicotyledonous plants; without zinc, wheat and barley die in the early stages of growth, and buckwheat, sunflowers, broad beans and red kidney-beans never come to full maturity or produce seed.

The search for so-called trace elements in foods and in the tissues and fluids of the body is beset with difficulties. The quantities are often too small to be measurable with success by the usual devices of the analytic chemist. In recent years he has therefore called the spectrograph to his aid. In this way exceedingly small amounts of the less familiar inorganic tissue constituents (or contaminants) can be identified in surprisingly small samples of material. By means of spectrographic analysis, Dutoit and Zbinden[2] have investigated the ash of human organs. Rose quotes them as finding chromium, copper and tin in practically all organs; silver and aluminum somewhat less widely distributed; cobalt and nickel in the pancreas but not the liver; titanium in the lungs, only traces elsewhere; zinc especially in the generative organs, thyroid, liver and kidney; tin in the suprarenal glands, and all of these elements in the blood. Spectrographic analysis of the ash of milk has shown traces of arsenic, boron, titanium, vanadium, rubidium, lithium and strontium, heretofore not known to occur in milk.[3]

The latest spectrographic analyses of human tissues come from England. Sheldon and Ramage[4] of Norwich designate as the universally recognized constituents of protoplasm the elements C, H, O, N, P, S, Na, K, Mg, Ca, Cl and Fe. Their latest studies suggest that copper is a universal, and is probably an essential constituent of living tissue. It occurs in greater concentration in fetal tissues than in adult, and reaches its maximum amount in the fetal liver, where the percentage of copper may be as much as ten times in excess of that present in the maternal liver. This is what one might expect in view of the alleged importance of copper in hematopoiesis in early life. Manganese occurs spasmodically in many tissues but is chiefly concentrated in the liver, pancreas, suprarenal and kidney. It is present in bile, fetal bile containing a high proportion. In the blood it appears to be confined to the serum. More surprising are some of the added observations. Rubidium is almost as widely distributed as copper and occurs in greatest concentration in the heart and in striated muscle. Silver is found to a less extent than the preceding metals but appears to be a normal constituent of the thyroid and the tonsil. Lead, strontium and lithium were found to occur spasmodically. One's first impression naturally is to regard all these rarer "trace" elements as contaminants rather than essentials or as physiologically significant. The experience of the past few years with iodine and copper, for example, is a warning to keep an open mind on the subject.

## THE RECTAL ADMINISTRATION OF SUGAR

The vogue that was attached some time ago to the use of nutrient enemas has disappeared almost completely. There are, of course, not infrequent indications for rectal feeding under conditions in which the oral path of administering food offers temporary difficulties. The earlier attempts to introduce such nutrient products as milk or other semiliquid foods into the rectum to supply imperative needs in the body usually ended in disappointment. It became clear after a time that digestion is a prerequisite for absorption of the foodstuffs. The opportunities for digestive hydrolysis in the lowest reaches of the bowel are extremely limited. Actual investigations presently showed that rectally introduced proteins and fats are returned with the subsequent evacuations of the bowel. One fact, the fairly ready absorption of water from the lower bowel, stands out conspicuously. Hence the alleged benefits of the rectal enema were probably for the most part attributable to the absorption of water and perhaps also salts. In any event it is not unlikely that administration of fluid by rectum is a more useful procedure under some conditions of dehydration than is commonly believed and that it deserves greater recognition in practical medicine.

The end-products of the digestion of sugars are monosaccharides, among which dextrose stands out as the most conspicuous and physiologically characteristic; for dextrose is the normal circulating carbohydrate of the blood. On this account it has been assumed, or at any rate hoped, that dextrose can be freely administered parenterally when indicated. The sugar is, in fact, currently used for intravenous injection; and it can be administered without loss in other ways. A recent textbook[1] clearly summarizes the present views with the statement that the nutrient enema furnishes a valuable means of giving both food and water to the patient who for any reason cannot be adequately fed by stomach. There are, however, definite limits as to both the quantity and the kind of food that may be given in this manner; these limits should be clearly recognized by the physician. The author points out that the injected material does not go beyond the ileocecal valve, unless perchance that valve is incompetent, and all absorption therefore as a rule takes place in the colon. Since the large intestine is intended chiefly as a reservoir in which no appreciable digestion takes place and from which only water and salts are normally absorbed, he adds, its usefulness as an organ of nutrition is obviously limited.

On these accounts "it is seldom if ever advisable to include in them anything other than water, glucose and sodium chloride."[1] Even dextrose has recently fallen under the ban of dependable value. Scott and Zweighaft[2] of the Department of Physiology at Columbia University have administered enemas containing from 20 to 40 Gm. of dextrose, in 10 per cent solution, by rectum to many healthy persons. They have been unable to demonstrate any rise in the blood sugar content as a result of such procedures. They found that a variable and frequently considerable amount of dextrose administered by enema may be recovered from the stools after two and one-half hours. According to Scott and Zweighaft, the sugar that was not recovered in the stools may possibly have risen higher in the large bowel because of antiperistalsis or for some other reason, there to be retained for a slow absorption, partial destruction by fermentation or a later return. A certain amount may have entered the blood stream at a rate too slow to elevate the blood sugar concentration significantly. In any event these studies fortify the views of those earlier investigators[3] who have become skeptical of the practical value of the rectal administration of dextrose.

## A COMPARISON OF MILK FROM THE TWO BREASTS

In a recent review of the nutritive aspects of human milk, Macy[1] of the Research Laboratory of the Children's Fund of Michigan emphasizes the fact that at times not only do the most carefully prepared scientific formulas fail to satisfy the nutritive needs of a particular infant but even mother's milk may fail. Therefore, renewed interest has been focused on mother's milk and it is being subjected to careful chemical and biologic investigation in respect to its adequacy in all known details and the possibility of its improvement through maternal care. Macy points out the difficulties of defining a standard composition of breast milk because milk secreted by different women has been shown to vary in composition between wide limits. Furthermore, it has been demonstrated that the following conditions may be effective in altering the quality and quantity of milk secreted: the size and anatomic structure of the mammary gland; the amount and kind of food intake; heredity; the environmental conditions, such as fresh air, sunshine, the amount and intensity of work, rest and exercise; and the emotional make-up of the individual, as well as extraneous disturbances. Evidently there are many influences operating to change not only the total quantity of mother's milk secreted but its integral components. The circumstance that an infant has been fed at the breast is no guarantee of a fixed sort of nutritive intake. Macy notes that even under standardized methods of expression, sampling, and analysis at four-hour intervals during the twenty-four hour day, changes have been observed in the flow and chemical composition of breast milk that are of nutritional and clinical significance.

[1] Macy, Icie G.: The Nutritive Aspects of Human Milk, Yale J. Biol. Med. 4: 451 (March) 1932.

The quantity of milk secreted by a lactating woman is dependent on the individual capacity of the mammary glands. This thesis has been further established by studies in the Detroit laboratories, where Brown, Macy, Nims and Hunscher[2] have measured the output and composition of milk from the two mammae of women. The two breasts often function differently in the total production of milk and milk nutrients. For example, the total daily quantities in some cases showed differences as great as 346 cc. even under rigidly controlled and standardized conditions. The observers believe that it is logical to expect greater inequalities in total volume output when the baby is the chief performer in securing the milk. Such observations, they state, are significant in considering the nutritional status of infants nourished exclusively on the milk from one breast.

The principal determinations, however, concerned the actual composition of the milk from the two breasts. Earlier conjectures had contemplated the existence of differences. The comment was made, for instance, that differences in the quality of milk from the two mammae were to be expected as the natural sequel of their relative anatomic position in relation to the blood supply. On the contrary, it has been found by the Detroit workers that the two mammae secrete milk uniform in the percentage concentration of fat, protein, lactose, total solids, solids not fat, total ash, calcium and phosphorus. At least this is true under carefully controlled conditions of milk expression and analysis, and on the basis of samples taken at each four hour interval during the twenty-four hour day. This indicates uniformity in cellular activity in the two glands. It has been declared, as Macy and her co-workers point out, that the processes involving the production of the milk fat are governed by a mechanism entirely separate from that regulating other milk constituents, although the actual processes involved remain obscure. The formation of fat has been attributed to a breaking away and degeneration of mammary gland cells. However, simultaneous secretion by the two glands of milk identical in fat concentration would imply that such a degeneration would proceed at the same rate and magnitude in the two breasts. Consequently, as Macy concludes, the data presented may offer convincing evidence against theories of the derivation of milk fat from cell degeneration, and evidence for theories of the formation of milk fat by processes of cellular secretion.

## HYPERVITAMINOSIS D AND ARTERIOSCLEROSIS

Following the discovery that irradiated crude cholesterol and then, more specifically, irradiated ergosterol (viosterol) promotes mineralization of rachitic bones, the observation was made that enormous overdosage with this potent therapeutic agent leads to the development of distinctly pathologic changes in the body. It was variously stated that irradiated ergosterol, as customarily employed, contained a toxic substance as well as a calcifying principle. The characteristic lesions resulting from administration of excessive amounts of this material are areas of calcification widely distributed in the tissues. Vanderveer[1] has recently reported observations of hypervitaminosis D and arteriosclerosis which have a decided bearing on the multiplicity of effects induced by overdosage with irradiated ergosterol. Rabbits were employed and the tissues were examined microscopically after spontaneous death. Gross examination of the aorta showed "an irregularity of contour from an outpouching and twisting of its walls." When cut open, grayish, plaquelike depressions were seen on the intimal surface, these areas being "bounded by the normal arterial wall, which had the appearance of a fold in this situation." Further examination indicated that the arteriosclerosis thus produced is not specific. Lack of round cell infiltration showed that inflammatory processes had no part in its development. It appears that a preliminary change of nonspecific nature occurs in the matrix surrounding the elastic fibers in the media, which change is followed by a deposition of calcium salts around the fibers in that region. The resulting inhibition to the mechanical action of the elastic fibers is apparently responsible for the characteristic circulatory disturbances and for hypertrophy of the heart and smaller blood vessels. The fibers are stretched out and fixed by the incrustation of lime salts, so that at death the usual postmortem contraction does not take place; these areas appear as dilatations from the outside of the vessel and as thin places in the vessel wall in microscopic section. Similar examination of cardiac and gastric muscle and of the kidneys was made. Calcification due to hypervitaminosis D appears to follow a preliminary injury to the tissue concerned. The cementing substance around the elastic fibers and muscle cells as well as tissues undergoing hyaline degeneration seem to be favored loci for deposition of lime salts. Vitamin D has only recently been isolated and prepared in crystalline form;[2] this substance is presumably a definite chemical compound. It will be of great interest to determine whether or not the observed toxic properties of irradiated ergosterol can still be demonstrated with crystalline vitamin D.

## Association News

### PERSHING HALL MEMORIAL

The total sum to date for the Pershing Hall Memorial is $2,510.10. The following list represents the most recent contributors:

C. L. Ogle, M.D., Grants Pass, Ore.
Herman L. Kretschmer, M.D., Chicago.

### MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 2:25 to 2:30 p. m., over Station WBBM (770 kilocycles, or 389.4 meters), and on Friday from 1:25 to 1:30 p. m. over Station WBBM and other stations of the Columbia Broadcasting System.

The program for the week is as follows:

May 16. Why Plant a Garden?
May 18. Hot Cereal and Milk.
May 20. Sick Enough.

There is also a fifteen minute health talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM, Chicago.

The program for the week is as follows:

May 21. What To Do — What To Do.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**License Revoked.**—At a meeting of the state board of medical examiners in Los Angeles, February 2, the license to practice medicine and surgery in the state of Dr. Clarke S. Smith, was revoked on a charge of violation of his probation (THE JOURNAL, Aug. 8, 1931, p. 395), testimony being introduced to the effect that he is now incarcerated at the Spadra State Hospital for Narcotic Addicts. Dr. Smith was committed to the hospital in January for a term of not less than eight months or more than two years.

**Society News.**—Dr. Benjamin Y. Katz addressed the Los Angeles County Medical Association, April 21, on "Erysipelas of the Pharynx and Larynx," and Dr. Norman J. Kilbourne, "Leg Ulcers of Unrecognized Etiology—X-Ray Diagnosis of Circulatory Diseases with Uroselectan."——Dr. Robert B. Greenough, Boston, addressed the San Diego County Medical Society, May 5, on "What the Doctor Can Do in the Control of Cancer," and Dr. Henry J. Ullmann, Santa Barbara, "The Work of the Cancer Commission."——The Oakland Urological Club was recently organized. Among others, Dr. Arthur E. Dart spoke at the initial meeting on "Recurrent Adenoma of the Prostate."

**Survey of Heart Disease.**—All forms of heart disease have been made reportable in San Francisco for a period of three months, beginning March 15, 1932, with the possibility of extending the time to one year, in a city-wide survey on heart disease morbidity. Collaborating in the survey are the San Francisco Department of Public Health and the San Francisco Heart Committee, which constitutes a joint affiliation with the San Francisco County Medical Society and the San Francisco Tuberculosis Association. Physicians in the city have been provided with suitable forms for reporting all their cardiac cases. A final analysis of the data will be made after completion of the study. This summary will include, as a comparative study, two provisional surveys recently undertaken by the cardiac clinics section of the San Francisco Heart Committee, of which Dr. John J. Sampson is chairman.

**Summer Courses at the University.**—Summer courses for graduates in medicine will be offered at the University of California Medical School, San Francisco, June 6-18. The subjects to be presented are general medicine and surgery, ophthalmology, otorhinolaryngology, genito-urinary diseases, pediatrics, circulatory diseases, diseases of the blood-forming organs, diseases of the endocrine glands, including diabetes, and diseases of the gastro-intestinal tract, laboratory diagnosis, pathology and operative technic. There will also be symposiums in the departments of medicine and surgery, daily noon lectures and clinicopathologic conferences and round table discussions on three evenings each week, open to the medical public free of charge. Among those giving courses in the summer session at the university, June 23-August 5, will be J. W. Bridges, Ph.D., professor of abnormal psychology, McGill University Faculty of Medicine, and Mark A. May, Ph.D., professor of educational psychology at Yale University. Professor Bridges will offer two courses, one on personality, normal and abnormal, and the other on abnormal psychology. Professor May will give one course on personality and character tests.

### GEORGIA

**State Medical Meeting.**—The eighty-third annual session of the Medical Association of Georgia will be held, May 17-20, in Savannah with headquarters at the Hotel DeSoto, and under the presidency of Dr. Arthur G. Fort, Atlanta, who will speak on "Economic Drift of Modern Medicine." Dr. Dean Lewis, Baltimore, will deliver the Abner Wellborn Calhoun Lecture on "Clinical Manifestation of Malignant Disease." Public meetings, Wednesday, will be addressed by Drs. William Mithoefer, Cincinnati, on "Relation of Diseases of the Nasal Accessory Sinuses to Systematic Derangements," and Walter C. Alvarez, Rochester, Minn., "Practical Points in the Care of Patients with Indigestion." At a meeting, Thursday, Dr. William R. Dancy, Savannah, will be presented with the Crawford W. Long Memorial Prize. There will be symposiums on sinus disease and the psychoneuroses, and public health. Scientific papers to be presented will include "Tuberculosis of the Kidney," Wallace L. Bazemore, Macon; "Abnormal Ureters," Spencer A. Kirkland, Atlanta; "Perinephritis Abscess," Emmet B. Anderson, Americus; "Effects of Injections of Ovarian Follicular and Anterior Pituitary Hormones on Conception and Pregnancy in Laboratory Animals," George Lombard Kelly, Augusta; "An Efficient Method of Traction for Fractures of Femur," Charles H. Watt, Thomasville; "Method of Precision in the Diagnosis of Early Pregnancy (Aschheim Zondek Test)," H. F. Sharpley, Jr., Savannah, and "Rickets," Mercer Blanchard, Columbus. The annual dinner of the alumni of Emory University School of Medicine will be held Wednesday, as will the annual dinner of the alumni of the University of Georgia Medical Department.

### ILLINOIS

**Personal.**—Dr. J. C. Westervelt, Shelbyville, recently completed fifty-four years in the practice of medicine; Dr. Westervelt has served also as mayor of the city for several terms.

### Chicago

**Personal.**—Dr. James H. Hutton, Chicago, has been appointed consulting endocrinologist to the hospitals of the Illinois State Department of Public Welfare.

**Society News.**—A symposium on Perthes' disease was conducted before the Chicago Roentgen Society, May 11. The participants included Drs. Dallas B. Phemister, Robert C. Lonergan, Marcus H. Hobart and Gentz Perry.——At a recent meeting of the Chicago Society of Allergy, Dr. Leon Unger was made president, and Dr. Meyer R. Lichtenstein, secretary. Dr. Isadore Pilot is vice president.

**Cook County Hospital Graduate Clinics.**—The seventh annual postgraduate clinics by the attending staff of Cook County Hospital will be held under the auspices of the Chicago

---

[2] Crystalline Vitamin D, editorial, J. A. M. A. **97:** 1628 (Nov. 22) 1931.

Medical Society, June 6-18. The object of the clinics is to furnish information which will aid the practicing physician in the diagnosis and treatment of the more important medical and surgical diseases. Special emphasis will be given to diagnosis, operative technic, pathology and the recent advances in medicine and surgery. The clinics will be divided into two main groups—medical, including the medical specialties, and surgical, including the surgical specialties. They will be held simultaneously throughout the day in two large amphitheaters. Special demonstrations in obstetrics and gynecology will be arranged. A fee of $10 is charged to cover the expense of organization.

**Albert B. Kuppenheimer Foundation.**—In January, 1931, following the death of Mr. Albert B. Kuppenheimer, it was announced that he had bequeathed $1,000,000 to the University of Chicago for research and study in the field of venereal diseases. At a recent meeting of the board of trustees of the University of Chicago, the Albert B. Kuppenheimer Foundation was established and a committee was appointed to allocate the funds. This committee is composed of Drs. Joseph L. Miller, clinical professor of medicine; Oliver S. Ormsby, clinical professor of dermatology, Rush Medical College; Samuel W. Becker, associate professor of dermatology; Oswald H. Robertson, professor of medicine and acting chairman, department of medicine; Dallas B. Phemister, professor of surgery and chairman of the department of surgery; Fred L. Adair, professor of obstetrics and gynecology; Franklin C. McLean, director, University of Chicago Clinics, and Frank R. Lillie, Sc.D., dean, Division of Biological Sciences. The bequest, which has suffered considerable shrinkage since the original announcement, has been turned over to the university. In accordance with the terms of the bequest, the income is to be expended wholly within the University of Chicago, of which Rush Medical College is a part.

## IOWA

**Annual Renewal Fees Due Before June 1.**—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license a licentiate must make a written application for renewal to the state department of health before June 1, enclosing the renewal fee of $1. If a license expires by reason of the licentiate's failure to renew it, it can be reinstated without reexamination only on the recommendation of the board of health and the payment of the overdue fees.

**Conference on Child Health.**—The Iowa White House Conference on Child Health and Protection was held in Des Moines, April 14-15, with Dr. Daniel C. Steelsmith, state health commissioner, presiding as general chairman. Among the many speakers on the program were Drs. Everett D. Plass, Iowa City, on "Study of Maternal and Neonatal Mortality in Iowa"; Erval R. Coffey, U. S. Public Health Service, "Rural Health Organization"; Andrew H. Woods, Iowa City, "Mentally Handicapped"; Dennis H. Kelly, Des Moines, "Study of Rheumatism in Children in Iowa"; Milford E. Barnes, Iowa City, "Training of Personnel"; Jacob Breid, Toledo, "Indian Children"; Mark L. Floyd, Iowa City, "Chronic Nonspecific Lung Infections in Children in Iowa"; Mae H. Habenicht, Des Moines, "The Handicapped"; Edward H. Lauer, Ph.D., Iowa City, "Physical Education and Recreation," and George D. Stoddard, Ph.D., Iowa City, "Infant and Preschool Child."

## KANSAS

**Typhoid at College.**—Seven cases of severe illness, said to be typhoid, with one death, occurred among students at the Kansas State College of Agriculture and Applied Science, Manhattan, recently. The source was traced to a boarding house near the college. Although all the food handlers had previously been tested, it was later discovered that one of the pantry cook's daughters had typhoid about two years before. It was also brought out that a niece had it about the same time as the daughter. Following another test which was positive, the pantry cook was discharged, since which time no further cases have been reported.

## KENTUCKY

**Outbreak of Food Poisoning.**—Thirty-six students became ill at Cumberland College, Williamsburg, recently, of food poisoning. Investigation disclosed that thirty-three of the thirty-six students had eaten fruited cream dessert. The cook ate the dessert Friday morning and was not sick, but ate some left over in the icebox and had an attack similar to the attacks of the students on the previous day. The remainder of the student body, about sixty-five students, ate "any and all of the supper dishes" and had no ill effects. Examination tests made on all persons employed at three dairies were negative for typhoid or paratyphoid. The conclusions of the investigation indicate that the probable causative agent of the outbreak was the meat and bread dressing which was prepared Thursday and reheated Friday evening, after having remained for some time without refrigeration.

**Society News.**—A symposium on diseases of the ear and some complications was a feature of the meeting of the Jefferson County Medical Society, April 18; the speakers were Drs. Albert L. Bass, Walter Dean, Gaylord C. Hall and Franklin Jelsma, Louisville. Dr. Thomas Cook Smith, Louisville, read a paper before the society, April 4, on "The Premature Infant." Dr. James Duffy Hancock, Louisville, addressed the society, May 2, on "Nonparasitic Abscess of the Liver." ——The Boyd County Medical Society was addressed in Ashland, April 2, by Drs. Albert L. Bass, and Claude T. Wolfe, Louisville, on hay fever and trachoma, respectively.——Speakers before the Christian County Medical Society, April 19, included Drs. Robert Lyle Motley, Memphis, on "Normal and Abnormal Heart Physiology"; Thomas D. Moore, Memphis, "A New Method of Treating Prostatic Obstruction"; William D. Haggard, Nashville, "Cancer of the Colon and Rectum," and Carl R. Crutchfield, Nashville, "Thyroid Surgery with the Radio Knife."——The Four-County Medical Society was addressed, April 28, by Drs. John L. Jones and Philip F. Barbour, Louisville, on diphtheria and scarlet fever and diagnosis and treatment of pneumonia in children, respectively.

## MARYLAND

**Dr. Sigerist Succeeds Dr. Welch at Johns Hopkins.**—Dr. Henry E. Sigerist, director of the Institute of History of Medicine at the University of Leipzig, Leipzig, Germany, has accepted the chair of the history of medicine in Johns Hopkins University Medical School. He will assume his duties July 1. Dr. Sigerist will succeed Dr. William H. Welch, in whose name the chair was founded at the same time that the William H. Welch Medical Library was established. Dr. Sigerist succeeded Dr. Karl Sudhoff as director of the Institute of Medicine at the University of Leipzig in 1925 when, at the age of 70, Dr. Sudhoff retired. Dr. Sigerist gave a series of lectures at Johns Hopkins last October and November, as visiting lecturer in the history of medicine. He studied at the universities of Zurich, London, Leipzig and Munich and received his medical degree at the University of Zurich in 1921. Three years later he was made professor of the history of medicine there. Dr. Welch, who retired last June, was the first professor of pathology at Johns Hopkins, having served in that capacity from 1884 until 1916, when he became the first director of the School of Hygiene and Public Health (The Journal, Feb. 14, 1931, p. 536). In 1926 he resigned that position to accept the newly created chair of the history of medicine. Dr. Welch's eightieth birthday in 1930 was marked by an international celebration.

**State Medical Meeting and Election.**—Dr. Joseph Albert Chatard, Baltimore, was elected president of the Medical and Chirurgical Faculty of Maryland at its meeting in Baltimore, April 26-27. The vice presidents are Drs. Samuel A. Nichols, Clarksville; Elliott H. Hutchins, Baltimore, and William S. Seymour, Easton. Drs. Walter D. Wise and Charles E. Brack, Baltimore, were reelected secretary and treasurer, respectively. Dr. Randolph Winslow, who was nominated delegate to the American Medical Association, is the oldest living continuous member of the faculty, having been active in its affairs for fifty-five years. The Trimble lecture was delivered by Dr. Henry A. Christian, Boston, on "Digitalis in Relation to the Therapy of Heart Disease." Another Trimble lecture was given by Dr. Alexius McGlannan on "Postoperative Thrombosis and Embolism." Other speakers on the program included Drs. Joseph Albert Chatard on "Necrology"; John Mason Hundley, Jr., "Hyperplasia of the Endometrium"; Henry J. Walton, "Roentgenology in Obstetrical Diagnosis"; Warfield M. Firor, "Effect of Hypophysectomy on Rabbit Pregnancy"; Lay Martin, "Studies on a New Organic Material, Presumably an Enzyme, Secreted into the Gastric Juice"; Allen F. Voshell, "Progressive Pseudohypertrophic Muscular Dystrophy"; Lewellys F. Barker, "Relation of the State Board of Health to the General Practitioner"; Earle P. Clemson, "Acute Hydronephrosis; Hydro-Ureter," and William H. Pearce, "The Alcoholic Problem." At a general meeting, April 27, a portrait of Dr. Henry M. Hurd, the first medical superintendent of Johns Hopkins Hospital, was presented, as well as a picture of Dr. Caleb Winslow by his sons Drs. John R. and Randolph Winslow.

## MASSACHUSETTS

**Mental Hygiene Clinics.**—Two new child guidance clinics have been organized and started within the last two months in Gloucester and Lowell. The Gloucester Clinic is under the auspices of the Danvers State Hospital, and the Lowell Clinic under the auspices of the state division of mental hygiene. There are now seventy-eight mental hygiene clinics for children and adults in the state.

**Courses for Graduates at Harvard.**—A special four months' course in internal medicine began at Harvard University Medical School, April 1, and will extend to August 1. A course in orthopedic surgery begun in April will be continued through May. Beginning June 20 for six weeks, a course in internal medicine at the Massachusetts General Hospital will be carried on in charge of Dr. Frank Dennette Adams. Dr. Samuel A. Levine will conduct a course in modern diagnosis and treatment of heart disease at the Peter Bent Brigham Hospital during July. There will be a symposium on genito-urinary surgery, July 11-16, which will be an intensive review of diagnostic and operative problems under the direction of Dr. William C. Quinby. Full information may be obtained from the assistant dean, Courses for Graduates, Harvard University Medical School, Boston.

## MINNESOTA

**Physicians Appointed to Recodify Health Ordinances.**—A committee of six local physicians has been appointed in Duluth to recodify existing health ordinances, in cooperation with Dr. Mario McC. Fischer, recently appointed director of public health. When the proper health and sanitary code has been drawn up, it will be recommended for adoption to the city council with simultaneous recommendation of repealing all existing health ordinances. Following adoption of the new ordinance, the committee of six will be appointed as the board of health under it.

**Dr. Rothrock Honored.**—Dr. John L. Rothrock, St. Paul, was recently the guest of honor at a dinner given by 125 members of the medical profession. Dr. Rothrock, who has practiced in St. Paul for more than forty years, was recently promoted to a professorship of obstetrics and gynecology at the University of Minnesota School of Medicine. He addressed the dinner meeting on "Medical Progress in the Last Forty Years." Although Dr. Rothrock's retirement from active practice has already been announced, he now intends to give up his practice gradually.

**State Medical Meeting at St. Paul.**—The seventy-ninth annual session of the Minnesota State Medical Association will be held, May 23-25, at the Auditorium, St. Paul, under the presidency of Dr. Melvin S. Henderson, Rochester. Hotel headquarters will be at the Lowry Hotel. The program will include clinicopathologic conferences, a medical economics meeting, and symposiums on functional disorders and pediatrics. Speakers to be heard at the meeting will include Edward A. Fitzpatrick, LL.D., Milwaukee; Drs. Olin West, Secretary, American Medical Association, Chicago; Walter Sebening, Frankfort-on-the-Main, Germany, and Theodore M. Davis, Greenville, S. C. Among the topics listed for discussion are the element of fear in the development of functional disorders; the appeal of quackery to the neurotic patient; glandular dysfunction as related to the sexual hormone; pathogenic parasites in man; surgical use of maggots; professional pharmacy as applied to the physician; hemorrhoidectomy—an anatomic method; preliminary hemostasis in goiter surgery; gradual decompression of the biliary system, and subdiaphragmatic and liver abscess. A fracture clinic will be held Wednesday afternoon.

## MISSISSIPPI

**State Medical Election.**—At the annual meeting of the Mississippi State Medical Association, April 14, Dr. James M. Acker, Jr., Aberdeen, was installed as president; Dr. John W. D. Dicks, Natchez, was made president-elect, and Dr. Thomas M. Dye, Clarksdale, was reelected secretary. The next annual session will be held at Jackson, May 9-11, 1933.

## MISSOURI

**Society News.**—Arthur I. Kendall, Dr.P.H., Chicago, among others, addressed the Jackson County Medical Society, May 10, on "Filtrability of Bacteria and Its Clinical Significance."——Dr. William L. Nelson addressed the St. Louis Medical Society, April 12, on "Interpretation of Abnormal Personality," and Miss M. E. Steele, social worker, Psychiatric Child Guidance Clinic, "The Genetic Development of Abnormal Personality."

**Malaria Control Program.**—It has been announced that the malaria control program of the Missouri Pacific Lines, which has been conducted for the last eight years, will be continued this year. The cost of this year's work will bring the total expended for this purpose to $120,000, part of which has been borne by the communities in which the work has been done. Mr. L. A. Henry, sanitary inspector and engineer, with headquarters in St. Louis, is directing the work. The program calls for the destruction of mosquito breeding places by oiling ponds and stagnant creeks, screening of windows and the distribution of quinine among residents of the communities.

**Suspend Clinical Years at Missouri.**—The clinical years of study at the University of Missouri School of Medicine will be suspended, beginning August 31, until such time as the university finances permit their continuance, it was announced, April 2. The third and fourth years of study were reestablished a year ago last fall by the board of curators, after having been discontinued since 1910. During the present academic year about twelve students have been enrolled in the third year, and the fourth year curriculum was to have gone into effect next fall. Provision has been made to transfer the advanced students to other institutions, and arrangements may be made whereby these students will receive their degrees from the University of Missouri on the completion of their course elsewhere. Concerning the suspension of the course, it was stated that the "suspension is temporary in character and is due entirely to the shortage of state funds. The establishment and maintenance of the third and fourth years in medicine at Columbia have been amply justified. The clinical facilities provided have been more than sufficient in practically all branches for modern, medical education."

## NEBRASKA

**State Medical Meeting at Lincoln.**—The annual meeting of the Nebraska State Medical Association will be held at the Lincoln Hotel, Lincoln, May 24-26, under the presidency of Dr. Lucien Stark, Norfolk. There will be symposiums on toxemias of pregnancy and cerebral birth injuries, prevention and treatment. Speakers at this meeting will include Drs. Thomas J. Kinsella, Glen Lake, Minn., on "Surgical Aspects of Pulmonary Tuberculosis"; Charles G. McMahon, Superior, "Traumatic Surgery in a Rural Hospital"; William J. Arrasmith, Grand Island, "Hyperthyroidism and Neurasthenia"; Ernest S. Wegner, Lincoln, "Infant Feeding"; Herbert H. Davis, Omaha, "Pathological Diagnosis and Treatment of Tumors of the Breast"; Karl A. Menninger, Topeka, Kan., "Sexual Neurosis in General Practice: Impotence and Frigidity"; Earle G. Johnson, Grand Island, "Diseases of the Gallbladder"; William J. Gentry, Gering, "Mumps with a Double Complication of Meningitis and Pancreatitis"; J. Frederick Langdon, Omaha, "Fascia Transplant in Treatment of Hernia"; Arthur D. Dunn, Omaha, "Cholecystography—Discussion of Intravenous and Oral Methods"; Charles M. Swab and Herbert F. Gerald, Omaha, "Present Status of Botulism in Food Poisoning"; Andrew C. Ivy, Chicago, "Physiology of Mucus Secretion with Some Experimental Results on the Prevention of Ulcer with 'Gastric Mucin' "; Walter D. Abbott, Des Moines, "Surgical Procedures on the Sympathetic Nervous System in the Treatment of Peripheral Vascular Diseases"; Walter C. Alvarez, Rochester, Minn., "Practical Points in the Handling of Patients with Gastro-Intestinal Disease."

## NEW JERSEY

**Society News.**—Dr. Harold Neuhof, New York, addressed the Hudson County Medical Society, May 3, on "Studies in the Diagnosis and Treatment of Pulmonary and Pleural Suppuration."——The Camden County Medical Society was addressed, May 3, by Drs. Vincent P. Del Duca on "Chronic Subdural Hematoma in an Infant with Necropsy Findings"; David F. Bentley, Jr., "Hematuria," and Hyman I. Goldstein, "Heredofamilial Angiomatosis with Recurring Familial Hemorrhages."——Dr. Edgar B. Friedenwald, Baltimore, addressed the Atlantic County Medical Society, May 13, at Atlantic City, on "Diet Problems and Therapeusis in Children."

**Tuberculosis Institute.**—A five-day postgraduate tuberculosis institute will be given at the Jersey City Medical Center, May 16-25, under the joint auspices of the Hudson County Medical Society, Hudson County Tuberculosis League, and the Hudson County Tuberculosis Sanatorium and Clinics. Dr. James Burns Amberson, Jr., assistant professor of clinical medicine, Columbia University College of Physicians and Surgeons, New York, will be the guest lecturer and will deliver a didactic lecture each day, followed by bedside instruction. Dr. Amberson's subjects will be: pathology and pathogenesis;

x-ray and physical diagnosis; symptomatology and clinical course of tuberculosis; nontuberculous chest diseases and differential diagnosis, and treatment of tuberculosis.

**Courses in Pharmacy.**—The New Jersey state board of pharmacy, Trenton, adopted a resolution, March 1, governing the approval of four year courses in pharmacy. Courses totaling less than 800 hours of instruction per college year for each of the four years of the course and which do not include at least 40 per cent of laboratory work are among those which will not be approved. In the near future, the state board reports, it will request all colleges of pharmacy desiring to submit their courses for approval to do so. In 1929, the board adopted a resolution making it mandatory for applicants for registration as pharmacists in New Jersey, who begin their college course in pharmacy any time after Jan. 1, 1932, to submit proof of graduation from a four year course in a college of pharmacy approved by the board. A resolution was adopted in 1930, declaring that the board's approval shall be confined to such courses and institutions as will recognize the need for fundamental training in physics, chemistry and biology as a basis for the course in pharmacy, as well as the need for the addition of so-called cultural subjects to the curriculum.

## NEW YORK

**Personal.**—Fenimore D. Beagle, who has been connected with the state health department thirty-four years, has been appointed secretary of the health department, succeeding Dr. Huntington Williams, who resigned last October to become director of health of Baltimore.——Dr. Lillian DeArmit, Schenectady, was recently appointed assistant school medical inspector in the medical inspection bureau of the New York State Education Department. She will maintain supervision of medical inspection and health service in the state normal schools.

**Changes at Penal Institutions.**—Dr. Frank L. Heacox, physician at Auburn prison, has been appointed superintendent of the State Training School for Women, Albion. He succeeds Dr. Gordon F. Willey, who became superintendent of the Bedford State Reformatory for Women, replacing Dr. Leo J. Palmer. Dr. Palmer was made warden of the new state "medium security prison" at Wallkill. The latter institution is reported to be a prison without walls, fences or bars, where inmates live in rooms, not cells. Only short-term convicts are to be sent to the new prison, which will eventually have a capacity of 500 prisoners.

### New York City

**Eighth Harvey Lecture.**—Dr. Albert Policard, Lyons, France, will deliver the eighth Harvey Society Lecture at the New York Academy of Medicine, May 19, on "Histochemistry: Present State and Future."

**Course on Tumors.**—Dr. William H. Woglom will give a course in the pathology and diagnosis of tumors at the Institute of Cancer Research in connection with the summer session of Columbia University, beginning July 5 and continuing six weeks. Classes will be held daily from 2 to 4 p. m., except Saturday, and the fee will be $37. Application should be made to the director of the summer session, Columbia University.

**Dr. Diner Retires as Dean.**—Dr. Jacob Diner is now dean emeritus of Fordham University College of Pharmacy, following his retirement as dean on account of ill health. Dr. James H. Kidder, a 1928 graduate of Cornell University School of Medicine, has been appointed to succeed Dr. Diner. Dr. Diner graduated from Fordham University School of Medicine in 1913. He is president of the New York State Board of Pharmacy.

**Study of Heart Disease in Children.**—The department of education is undertaking a city-wide study of cardiopathic children now attending regular classes in the elementary schools, the *Weekly Bulletin* states. Parents of children whose record indicates the presence of any cardiac abnormality will be requested to take the child to a physician who is also asked to give his opinion as to whether the child should be in a hospital or in a convalescent home; whether school attendance is advisable; whether attendance at a special class for cardiac patients is indicated, and whether the child should climb stairs.

## NORTH CAROLINA

**State Medical Election.**—Dr. John B. Wright, Raleigh, was installed as president of the Medical Society of the State of North Carolina at its annual meeting, April 20; Dr. Isaac H. Manning, Chapel Hill, was made president-elect, and Dr. Lewis B. McBrayer, Southern Pines, reelected secretary. The next annual meeting will be held in Raleigh, April 17-19.

## OHIO

**Society News.**—The Union Medical Association was addressed, April 13, by Drs. George N. Wenger, Massillon, on "Anal Pruritus"; Maxwell Harbin, Cleveland, "Surgery of the Knee Joint"; Alex M. Rosenblum, Youngstown, "Pneumonia," and David S. Arbuckle, Akron, "Relation of Sinus Disease to Asthma."——Dr. Harold E. B. Pardee, New York, addressed the Columbus Academy of Medicine, April 11, on arteriosclerotic heart disease.——Dr. James M. Pierce, Cincinnati, addressed the Montgomery County Medical Society, May 6, on "Hygiene of Pregnancy."

**New Admission Regulations at Cincinnati.**—Commencing in September, 1934, candidates for admission to the freshman class in the University of Cincinnati College of Medicine must present official evidence of three years of college preparation of not less than ninety semester hours, in a college of satisfactory standing. The following subjects must be included: chemistry; zoology or general biology; general physics; English; foreign language, and embryology. Preference will be given to those applicants who are graduates of approved colleges and to those who have completed three years of college work and who signify that they will receive their academic degree on the satisfactory completion of the first year of the medical course. Preference will also be given to those applicants for admission who, in the opinion of the committee on admission, present evidence of high achievement in their college education and who are most likely to succeed in medicine, rather than to those who present the largest number of hours credit, or who have limited their preparation to the premedical sciences. Candidates for admission to the freshman classes of 1932 and 1933 will be required to present the minimum requirements in current effect at the school.

## OKLAHOMA

**Society News.**—At a recent meeting of the Southern Oklahoma Medical Society in Duncan, the speakers included Drs. George N. Bilby, Oklahoma City, "Relation of Public Health to the Medical Profession"; Udonna C. Boon, Chickasha, "Iritis"; Horace Reed, Oklahoma City, "Surgery as an Aid in the Treatment of Advanced Pulmonary Tuberculosis"; Leander A. Riely, Oklahoma City, "Diseases of the Gallbladder," and Edward P. Allen, Oklahoma City, "Toxemia of Pregnancy." Dr. Dock Long, Duncan, also spoke.——The Muskogee County Medical Society was addressed recently by Drs. Francis B. Fite on "Early Day Surgery in Territorial Days"; Jesse L. Blakemore, "Obstacles Met and Overcome by the General Practitioner in Organized Medicine before Statehood"; Floyd E. Warterfield, "Early Day Practice," and Claude A. Thompson, "Organized Medicine, Its Outlook and Prospects at This Time and Since Statehood."

## PENNSYLVANIA

**Personal.**—Dr. Eugene A. Conti, Pittsburgh, was recently appointed medical director of Allegheny County, succeeding Dr. John R. Conover.——Dr. Frederick Whitney Davis has been appointed health officer of Lackawanna County, succeeding Dr. Frank R. Wheelock.

### Philadelphia

**Changes at Temple University.**—Announcement has been made of the following changes and additions to the staff at Temple University Medical School:

Dr. Lowrain E. McCrea, to associate in genito-urinary surgery.
Drs. James Merriman Lynch and Nathaniel Hurwitz, clinical assistants in medicine.
Dr. George D. Mulligan, clinical assistant in rhinolaryngology.
Dr. Joseph A. Parrish, clinical assistant in surgical research.
Dr. Joseph Weiner, instructor in medicine.

**Society News.**—The Obstetrical Society of Philadelphia was addressed, May 5, by Drs. Thaddeus L. Montgomery on "Lesions of the Placental Vessels," and Clifford B. Lull on "Cesarean Section in Philadelphia."——Among others, Dr. George U. Pillmore addressed the Philadelphia Roentgen Ray Society, May 5, on "Economic Problems of the Hospital Radiologist."——A symposium on cancer constituted the meeting of the College of Physicians of Philadelphia, May 4.——Drs. Lee A. Rademaker and Benjamin F. Buzby spoke before the Philadelphia Academy of Surgery, May 2, on "Effects of Blood in Experimental Peritonitis" and "Recurring External Dislocations of the Patella," respectively.——Harold S. Burr, Ph.D., New Haven, Conn., addressed the Medical Club of the Woman's Medical College of Pennsylvania, May 6, on "An Electrodynamic Theory of the Development of the Nervous System."

## WISCONSIN

**Society News.**—Dr. Irving F. Stein, Chicago, addressed the Kenosha County Medical Society at Kenosha, April 21, on "Value of Roentgen Diagnosis in Obstetrics."——Dr. Temple S. Fay, Philadelphia, addressed the Milwaukee Academy of Medicine, April 19, on "Management of Cerebral Trauma and Intracranial Pressure."——Dr. Thomas C. Galloway, Evanston, Ill., and Norbert Enzer made addresses before the Medical Society of Milwaukee County, April 8, on "Surgical Diathermy in Otolaryngology" and "Relationship of Pathology to the Practice of Medicine," respectively.——At a meeting of the Milwaukee Pediatric Society, April 13, Dr. Louis W. Sauer, Evanston, Ill., spoke on pertussis and Dr. George Light on otitis media and sinusitis in infants and children.

**Course in Obstetrics and Gynecology.**—A twelve weeks' course in obstetrics and gynecology will be conducted in southwestern counties of the state, beginning June 13. The program, which will be held in La Crosse, Tomah, Portage, Platteville, Richland Center and Monroe, is sponsored by the state medical society, the University of Wisconsin Medical School and the university extension division. The meetings in each center will be held on the same day each week for twelve weeks at the same time and place. The instructors will be Drs. Otto H. Schwarz, professor of obstetrics and gynecology, Washington University School of Medicine, St. Louis, and Everett D. Plass, professor of obstetrics and gynecology, State University of Iowa College of Medicine, Iowa City. Subjects to be covered will include the pelvis, pelvimetry and the contracted pelvis; antepartum and postpartum hemorrhage; causes, diagnosis and treatment; obstetrical analgesia and anesthesia; forceps: indications, contraindications, methods; management of breech presentations and version; cesarean section; uses, indications and abuses; management of normal pregnancy; complications of pregnancy including abortion and premature labor; management of normal labor and management of normal puerperium. The fee for the course is $30. Application may be made to the university extension division, room 108, Madison.

## WYOMING

**White House Conference and Health Officers' Meeting.**—A joint session of the Wyoming White House Conference on Child Health and Protection and the County Health Officers' Association was held in Casper, May 5-7. Drs. Joseph C. Kamp, Casper, spoke on "The Children's Charter"; Herbert L. Harvey, Casper, "Health Education"; Albert B. Tonkin, Riverton, "Maternal and Infant Mortality"; Neil C. Geis, Casper, "Infant and Child Care and Feeding"; Odra S. Pavy, Laramie, "Physical Examination"; Allan McLellan, Casper, "Growth and Development"; Freeman G. Huffman, Wheatland, "Communicable Disease Control"; John H. Goodnough, Rock Springs, "Preventive Medicine and Immunization"; William O. McDermott, Casper, "Sanitation"; Nathan E. Wells, Newcastle, "Medical Service and Administration"; Joseph R. Hylton, Douglas, "Tuberculosis of Spine in Children"; Platt W. Covington, Salt Lake City, "Public Health"; Thomas J. Riach, Casper, "Mental Health of Children in Wyoming," and Arthur G. Crane, Ph.D., president, University of Wyoming, "Children During the Depression." There were many other speakers on the program. Those on the program of the County Health Officers' Association included Dr. McDermott on "City Health and Administration"; Dr. Wells, "Control of Typhoid Fever"; David M. Sayles, Gillette, "Prenatal Care," and Walter O. Gray, Worland, "Tick Fever Immunization."

## GENERAL

**Directory of Occupational Therapists.**—Announcement was made, May 2, that the American Occupational Therapy Association, New York, is about to issue its first annual directory of qualified occupational therapists, which will include the names of those who applied and were found qualified for admission to the National Register established by the association early in 1931. It is hoped that this directory will protect hospitals and related institutions from unqualified persons posing as occupational therapists.

**Medical Bills in Congress.**—*Changes in Status:* S. 4273 has been favorably reported to the Senate, without amendment, authorizing an annuity to the widow of Dr. Aristides Agramonte, a member of the Yellow Fever Commission (H. Rept. 661). The Economy Bill, H. R. 11597, has passed the House as Part 11 of H. R. 11267, a bill making appropriations for the legislative branch of the government for the fiscal year ending June 30, 1933. The House eliminated all provisions in the bill relating to veterans, and in lieu thereof inserted a provision providing for a joint congressional committee to conduct a thorough investigation of the operation of the laws and regulations relating to the relief of veterans and to report to the Congress, not later than the first Monday in December, 1932, a national policy with respect to veterans and their dependents. *Bill Introduced:* H. R. 11927, by Representative Kurtz, Pennsylvania, to authorize the construction of a veterans' hospital in the counties of Blair, Centre, Clearfield or Cambria, Pennsylvania.

**Tuberculosis Meeting in Colorado.**—The annual meeting of the National Tuberculosis Association will be held in Colorado Springs, Colo., June 6-9, under the presidency of Dr. Alfred Henry, Indianapolis. Among speakers listed on the program are Drs. Henry Sewall, Denver, on "Allergy in Tuberculosis"; Theobald Smith, Princeton, N. J., "Modern Trends in Bacteriological Research"; James Burns Amberson, Jr., New York, "Comparative Value of Paper and Celluloid Films for Chest Roentgenograms; Report of 1,000 Cases"; Carl H. Greene, Rochester, Minn., "Treatment of Addison's Disease with Cortical Hormone of the Suprarenal Gland," and Col. Earl H. Bruns, Denver, "Nontuberculous Diseases Simulating Tuberculosis." Symposiums will be held on "The Blood Cell Count in the Diagnosis of Active Tuberculosis" and "Racial Aspects of the Tuberculosis Problem." Dr. Gerald B. Webb, Colorado Springs, will address the annual dinner meeting on Robert Koch. The Trudeau medal will be awarded at the opening session. The American Sanatorium Association and the National Conference of Tuberculosis Secretarie will hold meetings concurrently and the western branch of th American Public Health Association will meet, June 9-11.

**Medals Awarded.**—Two medals were presented by the National Academy of Sciences at its annual dinner, April 26, in Washington, D. C. One was the Public Welfare Medal, which was awarded posthumously to Wickliffe Rose "for his organization and direction of the work of the International Health Board of the Rockefeller Foundation by which he made, to the promotion of public health and welfare, a contribution of world-wide significance and importance." The announcement of the award was made in April, 1931, the medal to be presented at the next meeting of the Academy. However, Dr. Rose died in September, 1931, before the medal was presented and delivery of it was made to his son, H. Wickliffe Rose. The Public Welfare Medal is provided through the Marcellus Hartley Fund, a trust fund established in 1913-1914 through the gift of Mrs. Helen Hartley Jenkins, in memory of her father, Marcellus Hartley. The Mary Clark Thompson Medal and accompanying honorarium of $250 were presented to David White of the U. S. Geological Survey and a member of the academy, for his researches in paleontology. The trust fund providing this medal was established in 1919 by the gift of Mrs. Mary Clark Thompson for whom it was named.

## Naval Medical Journal Twenty-Five Years Old

The *Naval Medical Bulletin* celebrated its twenty-fifth anniversary with the April issue. The journal was first issued in April, 1907, under the editorship of Dr. William H. Bell, then a passed assistant surgeon. Succeeding editors have been Drs. Charles N. Fiske, James C. Pryor, Ralph W. McDowell, Theodore W. Richards, Joseph L. Nielson, L. W. Johnson, Robert C. Ransdell, J. S. Taylor, William M. Kerr, Luther Sheldon, Jr., and Robert P. Parsons. The bulletin has always been a quarterly publication except for a period from January, 1922, to December, 1925, when it was issued monthly.

## Dr. Dunbar Promoted to Rear Admiral

Capt. Arthur White Dunbar was promoted to the rank of rear admiral in the medical corps of the U. S. Navy, March 29. Dr. Dunbar, who was commissioned an assistant surgeon in the medical corps of the navy, Oct. 10, 1894, is at present attached to the bureau of medicine and surgery, navy department, Washington, D. C., as inspector of medical department activities on the East Coast. Admiral Dunbar was ordered to duty as executive and later succeeded to the command of the first hospital ship, the U. S. S. *Relief*. During the World War he was in command of the Hospital Ship *Comfort* and later in command of the Hospital Ship *Mercy*. During the period April, 1925-June, 1927, he served as assistant to the chief of the bureau of medicine and surgery, navy department.

### The Decline of Tuberculosis in England

The Ministry of Health has published a report on tuberculosis by Dr. A. S. Macnalty, senior medical officer for tuberculosis, which is a comprehensive study of the present position regarding prevention and treatment and a review of the incidence and mortality during the whole period for which figures are available. The salient fact is a great and steady decline. The mortality in England and Wales has fallen by 72 per cent since the decade 1851-1860. The ratio of deaths from tuberculosis to deaths from all causes shows a corresponding decline. Thus, taking the deaths from all causes as 100, the figures for deaths from tuberculosis were:

| | Males | Females |
|---|---|---|
| Decade 1851-1860 | 15.7 | 17.2 |
| Decade 1901-1910 | 11.4 | 10.2 |
| Quinquennium 1921-1925 | 9.5 | 8.3 |
| Four years, 1926-1929 | 8.5 | 7.1 |

Both the actual and the comparative mortality have fallen more rapidly in females than in males. The mortality per million of population was:

| | 1901 | 1929 |
|---|---|---|
| From pulmonary tuberculosis | 1,263 | 738 |
| From nonpulmonary tuberculosis | 544 | 194 |

However, tuberculosis is still responsible for 37,000 deaths per annum and for 31 per cent of all deaths between the ages of 15 and 45. Although the decline in mortality is proceeding with fair rapidity in this country and our mortality compares favorably with that of the majority of European countries, it is higher than that of New Zealand, Australia and Canada. In 1928 our mortality per hundred thousand of population was 75.5, while that of New Zealand was 40.9. For the age period 5-45 years, tuberculosis is the chief killing disease. Toward the end of childhood and in young adult life it is responsible for a higher mortality in females than in males. At this period approximately one third of the deaths from all causes among males and almost one half among females are due to tuberculosis, chiefly pulmonary. On the other hand, in middle life and old age the mortality from tuberculosis is much greater in males. The mortality both from pulmonary and from nonpulmonary tuberculosis is higher in urban than in rural districts. In recent years the figures of notification are available and tell the same tale as the mortality. In 1913, 80,788 cases of pulmonary and 36,351 cases of nonpulmonary tuberculosis were notified, while in 1929 the figures were only 57,274 and 18,682.

It is noteworthy that the decline of tuberculosis began before special attention was devoted to the problem. Dr. Macnalty attributes this to higher wages, an improved standard of living, and hygiene and public health measures, with segregation of advanced cases of pulmonary tuberculosis in poor-law hospitals. It was not till the last decade of the nineteeth century that energetic measures were taken against the disease and that the value of sanatorium treatment was appreciated. The diminishing figures year by year afford great encouragement to antituberculosis work.

### Tobacco Smoking Denounced

It has chanced that tobacco smoking has been denounced at the same time at two different societies. At a meeting of the Society for the Study of Inebriety, Dr. J. D. Rolleston opened a discussion on the cigaret habit. He said that travelers reported that it was prevalent in South America in the eighteenth century. Thence it spread to Spain, where Casanova spoke of it in 1767. Its diffusion over Europe began with the Crimean War, and Germany was the last country to adopt the cigaret largely. North America did not come under its spell until it had become universal in Europe. There had been a considerable increase in the habit since the Great War, especially among women. The cigaret differed from all other forms of tobacco smoking in nicotine content being lower but carbon monoxide higher. Moreover, furfurol, usually absent from the smoke of the pipe or cigar, and present only in small amount in that of the Turkish cigaret, was in large amount in that of the cheap cigaret. The *Lancet* had stated that habitual cigaret smoking was only slightly less harmful than drinking spirits between meals. It had been computed that each man, woman and child in the United States smoked 1,000 cigarets annually. "Smokers' throat" was mainly due to the pyridine content.

The medical profession was not unanimous as to the part played by tobacco in the causation of certain diseases, particularly those of the heart and especially angina pectoris. Many considered it a precursor of cancer. It was notorious that the deterioration of tuberculous persons who smoked was rapidly accelerated. Both smoking and the cocktail habit were detrimental in diabetes. Tobacco amblyopia was a definite ill effect. One high authority had predicted a large increase of cancer of the buccal mucous membrane from the universal indulgence in cigarets.

The tobacco habit was discussed also at the fifth annual meeting of the National Society of Non-Smokers. In the annual report it was urged that smokers should be banned from places in which food is served and that restaurants should provide non-smoking rooms. Young men were giving up smoking because they thought it effeminate, but Boy Scouts and even Girl Guides had succumbed to the habit. The chairman, Dr. Pryns Hopkins, referred to the statement made in the report of the discussion of Dr. Rolleston's paper that smoking soothed the nerves. The fact was that smokers were very irritable people when unable to smoke. Smoking had a tendency to impair the moral faculties; smokers seemed to lose certain qualities of truthfulness and consideration for others.

### Railway and Road Accidents Compared

The minister of health, Sir Hilton Young, speaking at an anniversary meeting of railway servants, said that 241 railway servants were killed and 17,997 injured in 1931 in the performance of their duties. But the number of passengers who were killed was only 76, while 5,000 were injured. These were remarkable figures for the passengers, considering the chances involved. They compared favorably with accidents on the roads, in which 7,000 were killed and 150,000 injured in the same year. He wished the public could be excited to take the same interest in automobile accidents they did in railway accidents.

### Deaths from Injection Treatment of Varicose Veins

It is generally held that the risks of the injection treatment of varicose veins are small. However, a number of deaths from pulmonary embolism have been recorded. In his recent oration to the Harveian Society on pulmonary embolism, Sir Bernard Spilsbury, the government pathologist, reviewed 120 fatal cases in which he had made or assisted at a necropsy. In three of these, pulmonary embolism was due to the injection treatment of varicose veins—in two, sodium salicylate was used, and in 1, sodium morrhuate. Sir Bernard thought that the rarity of this complication was a testimony to the comparative safety of the method, as to which originally he had some misgivings. Another case has just occurred and been the subject of an inquest, at which the incorrect statement was made that it was the first in this country. A woman, aged 62, received an injection in her left leg for varicose veins at the

German Hospital, London. She had pain afterward and remained in bed for a week, after which she went about her ordinary housework. She suddenly became faint and was found sitting on a sofa and asking for water. She died before medical aid could be summoned. The necropsy showed that death was due to a tubular clot of blood in the heart, 3 inches long and three-eighths inch in diameter. The coroner criticized the usual practice of allowing patients to get about after injection of varicose veins. He thought that it would be much safer for them to rest until such time as the clot in the vein had dispersed.

### Herpes Zoster and Chickenpox

The question of the possible identity of herpes zoster and chickenpox, as raised by Mr. Netter, was the subject of a recent discussion before the Société des médecins des hôpitaux de Paris. Mr. Armand Delille and Madame Trocmé reported an observation that has a bearing on the question. At the Hôpital Herold, these authors observed, October 12, in a tuberculous young girl undergoing pneumothorax treatment, who had been in the department since June, a thoracic herpes zoster of the eighth and ninth right dorsal roots. Exactly fifteen days later, October 27, two children, one in the neighboring cubicle, the other in the cubicle opposite, came down with a typical chickenpox. A third case of chickenpox developed the day following. This outbreak gave rise to a fourth case, fifteen days later. There had been no case of chickenpox in the department for more than a month. It was therefore considered reasonable to incriminate the case of herpes zoster as the cause of the cases of chickenpox. Netter also recalled similar cases of chickenpox in another hospital service, in children adjacent to a patient suffering from herpes zoster. Mr. Hallé confirmed this opinion, but Mr. Comby remained skeptical and advanced the theory that the contagion might have come from without, through visitors of the young patients. Mr. Apert stated that he had long held the same opinion as Mr. Comby, but that recent observations made in his department had served to change his point of view. Such happenings occur too often to be simple coincidences.

At a later session of the same society, the nervous disorders that are sometimes observed during chickenpox and that appear to show that the central nervous system is attacked, as is the case in herpes zoster, were discussed. Mr. Sendrall and Madame Dudevant reported a syndrome of choreo-athetosis that developed during convalescence from chickenpox. There appeared first a grave meningeal syndrome, followed by a paralysis of the lower limbs and motor disorders of a choreoathetosic type, which attacked at the same time the muscles of the arms, the head and the trunk. These symptoms, however, retrogressed spontaneously and the patient recovered without sequels. In connection with this communication, Professor Marfan stated at the following meeting that, in 1893, he reported a case of chickenpox in a child, which was associated with complete paralysis of the left arm. He referred these nervous symptoms to the action of the virus of chickenpox, but his conclusions were at that time rather doubted. But now practically all the authors who have studied this question are of this opinion and accept the possibility of a neurotropic action of the virus of chickenpox. Marfan recalled also a case of ophthalmoplegia externa that he reported in 1898; also cases of atrophy of the quadriceps, which followed this disease. The author confirmed thus the possibility of nervous lesions associated with chickenpox. Further, Mr. Cathala reported a case of facial paralysis that developed twelve days after the onset of chickenpox and was accompanied by a slight weakness of the right leg, with abolition of the achilles reflex. The father of this young girl, likewise affected with chickenpox, presented two days later a monoplegia of the left arm. All these accidents were, however, transitory. Netter recalled that the observations of Professor Marfan are the first that were published on the question and emphasized that such accidents were usually of a benign nature. Mr. Paraf cited similar cases, and also Mr. Babonneix. Mr. Sézary pointed out that Déjerine had observed such facts but regarded them as rare. He holds that, just like the spirochete, certain viruses may evolve and present affinities that are more and more neurotropic.

### The Law Pertaining to the Practice of Medicine

The text of the law pertaining to the practice of medicine in France, as passed by the senate, has been adopted without debate by the chamber of deputies. The provisions that present the greatest interest outside of France are the following: A physician must be a citizen of France and must possess a doctor's diploma in medicine, granted by the central government. Foreign countries in which physicians of French nationality are authorized to practice medicine may, however, demand of the French government diplomatic conventions relieving applicants "in certain cases" of the requirement of French citizenship. But a parity must be established between the number of physicians coming from countries with which conventions have been entered into, to practice medicine in France, and the number of French physicians practicing in those countries. The holders of a foreign diploma, certifying graduation as a doctor of medicine, who seek the doctor's degree granted by the French government must give evidence of possessing the credits required to enter on the course leading to the diploma certifying to adequate preparation in physics, chemistry and the natural sciences and must submit to an examination. They may not under any circumstances be relieved for more than three years of the obligation to submit such evidence. Foreigners holding a French "university diploma" in medicine will be subject to the same conditions, except as regards proofs of scholarship and the examinations. They may be relieved for four years of the necessity to submit evidence of scholarship. They may likewise be relieved of examinations, provided examinations do not in any case concern their knowledge of anatomy, physiology and the clinical subjects. No dispensations from examinations or from evidences of scholarship will be accorded to foreign students seeking a government doctor's diploma in medicine, irrespective of the length of time spent on studies in foreign countries. French naturalization will not be required of physicians who are regular practitioners of medicine in France the day of the promulgation of this law, provided they possess on that date the government doctor's diploma in medicine, nor of students who are taking a regular course of study leading up to such a diploma.

### An American Gift to the University City in Paris

Mrs. Harriett Hale Woolley has made the University of Paris a gift of $50,000 for the upkeep of rooms in the American Dormitory, which Dr. Gage had erected in the University City, Boulevard Jourdan. The right to occupy these rooms will be reserved to the beneficiaries of the scholarships established by Mrs. Woolley.

### International Congress on Urban Hygiene

The third International Congress on Technic and Urban Hygiene met recently in Lyons under the chairmanship of Dr. Tanon, professor of hygiene at the Faculté de médecine de Paris, the session continuing for a week. The first session was held in Prague, in 1930, and the second, last year, at Milan. At Milan, and also at Lyons, the congress met during the period that a large industrial and commercial exposition was held. Four hundred French and foreign delegates attended the congress, outside of the regular members. The first session was devoted to a presentation by Professor Greber on the importance of open spaces in laying out a large city, together with the presentation of photographs of cities illustrating this point, notably American cities. Chomel spoke on the accomplishments in hygiene and city development, already achieved or begun, at Lyons; Augustin Rey, on the importance of securing for dwellings the maximal amount of sunlight; Mazel and Robin on the rôle of the physician in the vocational guidance of young persons to prevent occupational diseases; Trillat on the influence of fogs; Turlin on the illumination of large cities; Kiemplin on the smoke evil; Verbouwe of Brussels on the danger of massive emissions of factory smoke, with citation of the fatal accidents that occurred, two years ago, in the valley of the Meuse; Henry Ferré, on the sanitary advantages of cremation; Knepen, on the suppression of moisture in walls by his system of permanent drainage; Violle of Marseilles, on the disinfestation of houses and individuals; Loir of Havre, on the need of an international society for the destruction of rats; Rey, on the location of hospitals with reference to the sunlight.

The congress passed five resolutions: one on the importance of the direction in which houses face, from the standpoint of the best insolation; a second on the minimum floor space of rooms of dwellings; a third on the necessity of renovating periodically the façade of dwellings; a fourth on the ventilation of rooms and dwellings, and a fifth on the abolition of the smoke evil. An exhibit of sanitary equipment and sanitary documents added to the interest of the congress. There were various new installations from the city of Lyons, new abattoirs, animal markets, and especially the new city of Villeurbane, where a central heating plant furnishes heat for 1,800 apartments and steam for 100 factories. The city of Lyons, owing to the initiative of its mayor, Mr. Herriot, is probably the most enterprising city in France, from the standpoint of breadth of view and the organization of city projects.

### The Excess of Physicians in France

The number of physicians in France continues to increase faster than the population. The total number is at present about 28,000. During the last year, 1,120 government diplomas have been conferred. It requires only a single arithmetical operation to foresee what the result will be in a few years. It may be considered that a physician practices, on an average, a period of thirty years. To maintain the present figure of 28,000, only 933 new graduates each year will be required, from which it appears that this year 187 more diplomas were issued than would be necessary to preserve the status quo. On the other hand, 1,120 graduates each year corresponds to a total of 33,600 physicians. However, the present total of 28,000 physicians constitutes, for the population of France, one physician for a little more than 1,400 inhabitants; while a total of 33,600, the figure toward which we are tending, represents one physician for less than 1,200 inhabitants. But since the present proportion is already too high, what will it be when the number of physicians shall reach 33,600? It should be noted also that, promotions having been more rapid in recent years, a larger proportion of the physicians are young practitioners, and for that reason the situation is more grave than it would be otherwise. It behooves the medical profession to give this question close attention. There are in France about 6,000 surgeon-dentists, and on every hand the syndicates of these practitioners are combating this overcrowding of their profession. While for the physicians an average career extending over thirty years may reasonably be assumed, it may be considered that, since the studies of the surgeon-dentists are begun at an earlier age and the studies are much less extensive, their opportunities to practice are just so much prolonged. Their practice will extend over a period of thirty-five years. Under these circumstances, in order to maintain the present total number of surgeon-dentists (6,000), 175 graduates annually would suffice, instead of 600, the present number. Six hundred graduates annually corresponds to 21,000 dentists, and one needs only to cite this figure to explain the grave error that has been committed, to which the medical profession should not remain indifferent. That is why limitation of the number of students to be admitted to the facultés is being seriously considered, as has been the case for some time in the large schools of technology.

### Death of Prof. Charles Debierre

The death of Charles Debierre, professor of anatomy at the Faculté de médecine de Lille, at the age of 79 has been announced. He was the author of numerous scientific works, among which is "A Treatise on the Anatomy of Man," which has been translated into several languages. He had many brilliant pupils. In 1897 he was appointed corresponding member of the Academy of Medicine. In 1911 he was elected senator of the department of Nord, which post he held until his death. Up to the age of 75, his duties as senator in Paris did not prevent him from returning three times a week to the Faculté de médecine de Lille to lecture. In the senate, he was an earnest advocate of the policy of making a strong course in the classics a preliminary requisite for students of medicine.

## BERLIN

*(From Our Regular Correspondent)*

March 21, 1932.

### Professor Forssell and the Campaign Against Cancer

Prof. Gösta Forssell of Stockholm has, of late years, carried on, in a most praiseworthy manner, a crusade against malignant tumors. He and three of his assistants, Berven, Heymann and Reuterwall, addressed recently the Berlin Medical Society. A large body of foreign physicians attended the meeting.

Forssell spoke on the organization of the cancer crusade in Sweden; Berven on the radiologic treatment of cancer of the mouth; Heymann on the radiologic treatment of tumors of the female genitalia, and Reuterwall on the anatomopathologic experiences at the Stockholm radiologic institute, which was established by Forssell in 1910, and is known throughout the world as the Radium Hemmet (Radium Home). The speakers were listened to with great attention by the large audience. The Swedish ambassador was present. Geheimrat Goldscheider warmly welcomed the foreign guests and emphasized the friendly relations that have long existed between the Swedish and the German peoples.

In the cancer campaign in Sweden the chief emphasis is laid on radiation therapy, which is in keeping with the training of Forssell. Its main feature is the centralization and full utilization of the available supplies of radium. Here is the main difference between the Swedish organization and the German, but, at the same time, also the deeper reason why Germany cannot adopt in its entirety the excellent Swedish organization. The methods of irradiation that have been developed in Sweden are based on a considerable supply of radium in the absolute sense and large in comparison with the population of the country. Forssell's Institute in Stockholm has alone more than 5 Gm.; the institute of the University of Lund more than 2 Gm., and the new institute in Gotenburg about 2 Gm. That represents a cost of several million marks. Germany has not the funds with which to purchase any such amounts of radium and consequently has been forced to develop especially the technic of the hard roentgen rays in combating tumors. The Berlin institute of the university, in the Charité Hospital, under the direction of Ferdinand Blumenthal, has about 1 Gm. of radium, and the Werner-Siemens-Institut, in the Moabit Hospital, under the direction of Frik, has 0.2 Gm. With regard to the best utilization of the German supply of radium, doubtless much could be learned from Sweden. We have divided up our forces too much. In Sweden, the whole radium supply of the country is collected in three places, where it works day and night in the campaign against cancer. Cancer patients have to go where the radium is—not the reverse. The Radium Hemmet was originally a research institute. Now it is a radiologic clinic which has beds for more than 1,500 patients annually, and, in addition, treats 8,000 outpatients. There is in Sweden, said Forssell, not a single village in which one or more cancer patients are not indebted to the Radium Hemmet or to one of its sister institutions. The central government pays the traveling expenses of needy patients, which necessitates the expenditure of about $25,000 annually. The most effective method of applying radium, in the opinion of these Swedish radiologists, is irradiation *à distance,* with filtered hard rays from the so-called radium cannon; but this method requires relatively large quantities of radium and can thus be successful only by means of centralization and economic utilization of all radium supplies. This point was emphasized repeatedly by the speakers —likewise the need of special cancer clinics and the special radiologic training of the physician, for which Germany has, to be sure, now made provision. The Swedes are not content with their supply of radium, and the large fund collected by popular subscription on the seventieth birthday of King Gustaf will enable them to increase it. At present there are in Stockholm 3 Gm. of radium available for treatment *à distance.* In addition, there are of course also the necessary roentgenologic apparatus and surgical assistance. The Swedish radiologist did not disparage the surgical method of treatment; on the contrary, he emphasized that in Sweden there were many excellently trained surgeons available for the treatment of cancer.

Berven discussed the technic and the excellent results in cancers of the mouth. The electrical production of heat within the cancer tissues (endothermy) is frequently resorted to as an aid to surgery. In gynecology, the results of the treatment discussed by Heymann are not so satisfactory. He reported, however, 20 per cent of permanent recovery (extending over more than five years) in statistics that were subjected to severe adjustment and that include numerous cases that were hopeless when treatment was first begun.

It was a thoroughly complete and reliable accomplishment that the Swedish scientists described at that evening session.

### The Hormone of the Pars Intermedia of the Hypophysis

Prof. Bernhard Zondek, whose researches on the sexual hormone, in collaboration with Aschheim, have achieved great importance, spoke recently before the Kaiser-Wilhelm-Gesellschaft on the hormone of the pars intermedia of the hypophysis. He succeeded in isolating an almost pure specimen of the hormone and then performed experiments to determine the significance of the hormone. He obtained the best results in cold-blooded animals, particularly in Leuciscus phoxinus, a cyprinoid fish about the size of a sardine, found in German waters. With the hormone of the pars intermedia he was able to produce a red stain on the body of the fish. It is therefore a hormone that influences the metabolism of colors. A number of color changes that occur in human beings are well known. In certain diseases, dark shades or losses of color are observed; but, above all, it is known that, during pregnancy, stains appear on the body surface of the woman. Heretofore it has not been fully established what caused these changes. The discovery of the hormone of the pars intermedia of the hypophysis opens now possibly the way to get back of the secret of the metabolism of colors.

### Lowering of the Fee Schedules

The economic distress in Germany has exerted a deep influence on the life of physicians. That private medical practice has suffered a terrible decline is not surprising to any one who is somewhat familiar with conditions, although it had previously been depressed by the extension of social insurance in Germany, during the years following the war. Under the influence of the wave of economy, Germany is seeking to make all possible retrenchments in order to protect itself against financial collapse. With the federal ministry of the interior and the federal ministry of labor, the federal commissioner for price control has entered into negotiations with the League of Physicians of Germany, the Deutscher Aerztevereinsbund and the Federal League of Dentists of Germany, concerning the question of lowering the fees for private medical and dental services. The negotiations resulted in the following agreement: The fees of the fee schedules of Prussia and the other states *(länder)* are to be made the basis for the determination of the fees of physicians and dentists. In evaluating their services, the physicians and dentists will consider the decreased purchasing power of the population, resulting from the changed economic conditions. The physicians and dentists reserve, however, the privilege, in particular cases, after previous expressed understanding with the patient, if his financial condition permits, of departing from these fee schedules. Local fee schedules established by medical and dental societies may be retained in force only after they have been revised and the fees have been reduced by at least 10 per cent, as against those of 1931. Furthermore, it must be recognized that the minimum fees of the local schedules may be shaded. The so-called chambers of physicians and chambers of dentists (in the absence of such chambers, the medical or dental societies) are establishing, if they have not previously existed, arbitration centers, where protests of patients against the fees charged them may be heard. In considering the nature and tone of these regulations, which certainly appear necessary, under the circumstances, one cannot help but regret in retrospect that the medical profession, which in the main offers and represents ethical values, has been drawn into the daily struggle of economic life, to such an extent.

## TURKEY

*(From Our Regular Correspondent)*

Ankara, March 30, 1932.

### Foreign Physicians in Turkey

According to the medical practice act of 1928, no one may practice in any form unless he is a Turkish subject and has a diploma from the Turkish medical school or from a foreign medical school recognized by the government.

According to article 77 of the present law, only those physicians, surgeon-dentists, dentists and midwives of foreign nationality who can produce official evidence to the effect that they have practiced medicine in Turkey before 1914 are according to the Lausanne treaty of 1923 permitted to continue to practice. Therefore a foreign physician desiring to practice medicine in Turkey qualifies by becoming a Turkish subject. Following application to this effect, the applicant comes before a jury for investigation. If it has been ascertained that the diploma is a true one and is the property of the applicant, and if the jury is convinced that he is a physician, a license is issued without further examination.

A foreign physician holding a teaching position at a government institution is not permitted to engage in private practice but may be called on for consultation. The intention to call a foreign physician for a teaching position led to the passing of a special law in December, 1930, reading as follows: On condition that he does not engage in private practice but practices medicine only on the inmates of the hospital clinics of the said institution, a foreign specialist physician may be appointed for a period of four years to direct the Gülhane Hospital, the postgraduate school for army physicians, where at the same time he is to lecture on military medicine.

### Influenza in Asia Minor

With the beginning of the new year, influenza appeared. Reports from all parts of the country, especially the big cities, showed that on account of the epidemic all schools were closed for two weeks. At first, complications were negligible, but they soon became serious and increased the fatality rate. It was at first thought best to close all motion picture houses, but they remained open and were mainly responsible for the spread of the disease; also, it was Ramazan, the month of the fast preceding the Bayram, when for thirty days believers abstain from food or drink from sunrise to sundown and go to the mosque for prayer. It was also at that time that the Koran was first read in Turkish instead of Arabic, which is quite an event. The people flocked into the great mosques by tens of thousands every night. Furthermore, unusually cold weather prevailed at this time.

### The Incidence of Rickets in Infants

As the result of an investigation into the incidence of rickets in infants, Prof. Dr. Ihsan Hilmi of the Chichli children's hospital in Istanbul points out that his investigation in Ankara, Kayseri and Istanbul revealed a relatively high incidence of rickets in city infants. Faulty nutrition is mainly responsible for this condition. Infants generally develop well during the first six months, but after that time, owing to the fact that the infant is still kept on milk only and the diet is devoid of vitamins and minerals, rickets soon develops. As a rule, during the first and second year the child receives milk and in addition a carbohydrate pudding. Among the poor, the infant is for economic reasons often kept on breast milk long beyond the required time. The age limit of the children studied in this investigation was 2 years; they were mostly brought to the hospital dispensary for advice concerning diet or because they were restless, sleepless or unmanageable or showed other signs of irregular feeding. In all, 3,797 children were studied, 2,060 boys and 1,737 girls. The accompanying table shows the incidence of rickets according to age and sex.

*Incidence of Rickets*

| Age | | Boys | | | Girls | | |
|---|---|---|---|---|---|---|---|
| | | Healthy | Rickets | Total | Healthy | Rickets | Total |
| 0- 6 months | 0- 3 months | 232 | 27 | 259 | 197 | 7 | 204 |
| | 3- 6 months | 177 | 71 | 248 | 171 | 37 | 208 |
| 6-12 months | 6- 9 months | 158 | 107 | 265 | 120 | 67 | 187 |
| | 9-12 months | 117 | 225 | 342 | 142 | 155 | 297 |
| 12-18 months | | 296 | 303 | 599 | 244 | 294 | 538 |
| 18-24 months | | 213 | 134 | 347 | 163 | 140 | 303 |
| Total (0-2 years) | | 1,193 | 867 | 2,060 | 1,037 | 700 | 1,737 |

Expressed in percentages, of infants up to 3 months of age, 10.2 per cent boys and 3.5 per cent girls had rickets; from 3 to 6 months, 28.6 per cent boys and 17.8 per cent girls; from 6 to 9 months, 40.3 per cent boys and 35.8 per cent girls; from 9 to 12 months, 65.8 per cent boys and 52.1 per cent girls; from 12 to 18 months, 51.0 per cent boys and 54.6 per cent girls; from 18 to 24 months, 38.0 per cent boys and 46.2 per cent girls; of all infants up to 2 years, 39 per cent of the boys had rickets and 35 per cent of the girls. The fact that rickets is more often seen in boys is due in part to the fact that the uneducated mothers still cling to the old custom of keeping boys on breast milk longer than girls, often until they are 2 years old. This study has also revealed that relatively few mothers (17 per cent) know what rickets is and what bearing it has on the development of the child. Out of 1,507 children having rickets, 266 were brought to the dispensary because the mother thought that the child was probably having rickets, 389 were brought to the dispensary because they were weak, anemic or suffered from loss of appetite, and 912 were brought for other reasons. Consequently the disease was already in a more or less advanced state. Because rickets had already become chronic and the infants were suffering from another disease in need of urgent treatment, the treatment for rickets could not always be started immediately. In 428 cases, or 27.3 per cent, urgent treatment was needed for disease other than rickets; in 1,076 cases, or 68.6 per cent, treatment for rickets was immediately started, and in 63 causes, or 4 per cent, treatment for rickets was given along with treatment for other diseases. Though the mothers were asked to bring the children at regular intervals and the need of their cooperation was explained to them, 995, or 63.5 per cent attended but once; 307, or 19 per cent, twice; 117, or 7 per cent, three times; 57, or 3 per cent, four times; 40, or 2.5 per cent, five times; 16, or 1 per cent, six times, and only a few seven, eight or nine times.

## RIO DE JANEIRO

*(From Our Regular Correspondent)*

April 15, 1932.

### Tuberculin Tests in Children Vaccinated with B C G

In a recently published article, Dr. A. de Carvalho of Rio de Janeiro reports on 723 intradermal reactions with large doses of tuberculin (up to 1 mg.) in 661 infants, from birth up to the age of 36 months, who had previously received the B C G vaccine by oral administration, in order to determine the presence of allergy to tuberculin in those infants. The general results confirmed the previous experience of the author. The reactions gave positive results in 582 tests (80.5 per cent); the results were negative in 119 tests (16.4 per cent), and there were doubtful results in 22 tests (3.1 per cent). The positive reactions seemed to be caused by the action of the B C G bacillus, because they occurred in vaccinated infants who did not live in a tuberculous environment. In the group of infants who lived among tuberculous persons, the percentage of positive results may be compared to that given by the first group (group without contact with tuberculous persons). However, there was a larger number of positive reactions among infants in the first group than among those in the second group. Allergy to tuberculin caused by the first vaccination with the B C G vaccine has an average duration of eighteen months.

### Identification of Leptospira from Man and from Rats

Dr. L. Salles Gomes, in a lecture before the Sociedade de Medicina e Cirurgia of São Paulo reported two cases of Weil's disease, previously observed by Drs. J. T. Piza and A. Ayrosa in Brazil. In these cases, the diagnosis was confirmed by histopathologic studies and by experimental inoculation. The author also reported a case of Weil's disease in which, after confirmation of the diagnosis, he succeeded in isolating the organism Leptospira icterohaemorrhagiae (Inada and Ido's type). He used the semisolid culture medium advised by Noguchi. The material from which cultures were to be made was collected by puncture from the kidney of guinea-pigs, previously inoculated with blood from the patient. All the culture tubes that were left at room temperature did not present any growth, while the culture tubes left at a temperature of 37 C. (98.6 F.) presented, on the eighth day, pure cultures of the spirochete. The author stated that in 1929 he also succeeded in isolating from wild rats of Sorocaba a type of Leptospira that is pathogenic for guinea-pigs. The genus was identified from culture tubes left at room temperature. He called the attention to the fact that Leptospira from rats could be identified from culture tubes left at room temperature, while, in order to identify the same genus from human blood, it was necessary to leave the culture tubes at a higher temperature: 37 C. (98.6 F.). He showed fresh smears of the organism with the darkfield, as well as histologic slides from the kidney and liver of experimentally infected guinea-pigs, which organs contained a large number of leptospiras stained by Levaditi's method.

## Marriages

George Courtenay Glass, Jr., Hartford, Conn., to Miss Gladys Boardman of New Haven, April 16.

William R. Johnson to Miss Naomi L. Allen, both of Baltimore, at Alexandria, Va., March 2.

James Quinn Dorgan, Columbus, Ohio, to Miss Viola Margaret Hall of Hines, Ill., April 14.

Richard T. McMurty to Miss Pauline Jett, both of Covington, Ky., April 15.

Eugene B. Elder, Knoxville, Tenn., to Miss Frances Williams, recently.

---

## Deaths

**Arthur Carl Heublein** ⊕ Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1902; member of the American Roentgen Ray Society, New England Roentgen Ray Society, Radiological Society of North America, American College of Radiology and the American Radium Society; roentgenologist to the Hartford Hospital; aged 52; died, April 7, of bronchopneumonia and myocarditis.

**William Stephenson** ⊕ Colonel, U. S. Army, retired, New York; College of Physicians and Surgeons in the City of New York, 1880; entered the army as an assistant surgeon in 1883; veteran of the Spanish-American War; was promoted through the various grades to that of colonel in 1912 and was retired in 1919, by the President, being 62 years of age; aged 76; died, April 11, of cerebral hemorrhage.

**Goldye L. Hoffman,** Chicago; University of Illinois College of Medicine, Chicago, 1915; member of the Illinois State Medical Society; associate in gynecology at her alma mater; president of the Medical Women's Club of Chicago; on the staffs of the Iroquois Memorial and Emergency hospitals and the Research and Educational Hospital; aged 38; died, April 17, of pneumonia.

**Julius Kangisser,** St. Joseph, Mo.; St. Louis University School of Medicine, 1912; member of the Missouri State Medical Association; served during the World War; aged 46; on the staffs of St. Joseph's Hospital and the Missouri Methodist Hospital, where he died, March 25, of sepsis following perforation of the intestine.

**Harvey Charles Maurer,** Beloit, Wis.; State University of Iowa College of Medicine, Iowa City, 1905; member of the State Medical Association of Wisconsin; served during the World War; on the staff of the Beloit Municipal Hospital; aged 49; was found dead in his garage, April 7, of carbon monoxide poisoning.

**Robert Menzies Mitchell,** Weyburn, Sask., Canada; Trinity Medical College, Toronto, Ont., 1892; past president of the Saskatchewan Medical Association; member of the American Psychiatric Association; formerly superintendent of he Weyburn Mental Hospital; aged 66; died in February.

**Louise H. Rainey Grieve,** Westerleigh, N. Y.; Woman's ledical College of the New York Infirmary for Women and hildren, 1893; for seven years a medical missionary in India; ed 68; died, March 4, in the Staten Island (N. Y.) Hos- al, of chronic fibrous tuberculosis and myocarditis.

**Allen Lawrence Lear,** Sewanee, Tenn.; University of the th Medical Department, Sewanee, 1908; member of the Ten- ee State Medical Association; for many years on the staff he Emerald-Hodgson Memorial Hospital; aged 45; died suddenly, April 2, of heart disease.

**Bessica Faith Curtis Medlar Raiche,** Santa Ana, Calif.; Tufts College Medical School, Boston, 1903; member of the California Medical Association; past president of the Orange County Medical Society; aged 57; died, April 10, of an accidental overdose of a sedative.

**Irvin Ebaugh,** Baltimore; University of Maryland School of Medicine, Baltimore, 1889; formerly professor of materia medica and therapeutics at his alma mater; aged 70; died, April 15, of hypertension, cardiovascular disease and embolus with infarction of the lung.

**Wilda Edwin Butler,** Hamden, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1897; member of the Connecticut State Medical Society; for many years on the staff of the Grace Hospital, New Haven; aged 61; died, April 12, of thrombosis.

**Charles Rees Palmer,** West Chester, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; aged 62; on the staff of the Homeopathic Hospital, where he died, April 6, of heart disease.

**Ozias Boynton Gould,** Utica, N. Y.; University of Vermont College of Medicine, Burlington, 1877; member of the Vermont State Medical Society; aged 78; died, February 21, of carcinoma of the intestine and intestinal obstruction.

**William Joseph Gorey,** Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1919; member of the Ohio State Medical Association; aged 37; died, April 14, in the Grant Hospital, of abdominal carcinomatosis.

**Pauline Myers Townsend Hanson,** Marshalltown, Iowa; Woman's Medical College and Hospital of Philadelphia, 1895; aged 66; died, April 5, in the Mary Thompson Hospital, Chicago, following an operation for carcinoma.

**Thomas Martin Hays,** Santa Anna, Texas; American Medical College, St. Louis, 1887; member of the State Medical Association of Texas; on the staff of the Sealy Hospital; aged 66; died, January 18, of heart disease.

**Lincoln E. Penny,** St. Paul; Hahnemann Medical College and Hospital, Chicago, 1885; for many years on the staff of the Ancker Hospital; aged 72; died, March 28, in St. Luke's Hospital, of hemorrhage of the stomach.

**Hiram Ansley Fulton,** Eau Claire, Wis.; Milwaukee Medical College, 1901; served during the World War; aged 54; died, April 5, in the Sacred Heart Hospital, of chronic myocarditis and cirrhosis of the liver.

**George David Parker,** Houston, Texas; Kentucky School of Medicine, Louisville, 1888; member of the State Medical Association of Texas; served during the World War; aged 69; died, March 26, of myocarditis.

**Elon B. Gilbert** ⊕ Geneseo, Ill.; Jefferson Medical College of Philadelphia, 1885; formerly president of the board of health of Geneseo; on the staff of the J. C. Hammond City Hospital; aged 72; died in April.

**Ettore Varvaro,** Clifton, N. J.; Royal University of Naples Faculty of Medicine and Surgery, Naples, Italy, 1896; aged 61; died, March 23, in St. Joseph's Hospital, Paterson, of cerebral hemorrhage.

**Virgil Wilson Leggett,** Hobgood, N. C.; University of Louisville (Ky.) School of Medicine, 1914; aged 42; died, March 26, at the Norfolk Naval Hospital, Portsmouth, Va., of acute endocarditis.

**Ivus Irvin Richmond** ⊕ East Bridgewater, Mass.; Harvard University Medical School, Boston, 1902; member of the school board; aged 62; died, April 8, in a hospital at Brockton, of pneumonia.

**William McSpadden Copenhaver** ⊕ Helena, Mont.; University College of Medicine, Richmond, Va., 1900; on the staffs of St. Peter's Hospital and St. John's Hospital; aged 56; was drowned recently.

**Charles B. Murphy,** Mannsville, Okla.; Ensworth Medical College, St. Joseph, Mo., 1897; aged 63; died, March 22, of injuries received when the automobile in which he was driving overturned.

**Leonard Woods Atkinson,** Patton, Calif.; Boston University School of Medicine, 1884; member of the California Medical Association; aged 72; died, February 27, in the Patton State Hospital.

**George D. Thomas,** Meadville, Pa.; Jefferson Medical College of Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; aged 77; died, February 18, of arteriosclerosis.

**James Harvey Bissell,** Troy, N. Y.; Albany Medical College, 1887; member of the Medical Society of the State of New York; aged 75; died, April 8, in the Leonard Hospital, of pneumonia.

**John Lawson Felder,** San Antonio, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1904; member of the State Medical Association of Texas; aged 49; died, January 16.

**Newell Eddy Lavely** ⊕ Detroit; University of Michigan Homeopathic Medical School, Ann Arbor, 1920; aged 39; died in April of lobar pneumonia, pericarditis and pulmonary embolism.

**Alexander Armstrong** ⊕ White Haven, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1895; aged 58; died, April 6, in the Pennsylvania Hospital, Philadelphia, of uremia.

**Adolphus B. Frame** ⊕ Piqua, Ohio; Medical College of Ohio, Cincinnati, 1868; Civil War veteran; on the staff of the Ball Memorial Hospital; aged 92; died, April 11, of angina pectoris.

**William Erastus Smith,** Whittier, Calif.; American Medical College, St. Louis, 1892; served during the World War; aged 61; died, February 25, in a hospital at Los Angeles, of uremia.

**Edmund Peter Arens,** Detroit; St. Louis University School of Medicine, 1908; aged 49; died, April 2, in the Deaconess Hospital, of carcinoma of the prostate and uremia.

**Walter B. Stewart,** Joliet, Ill.; College of Physicians and Surgeons of Chicago, 1888; member of the Illinois State Medical Society; aged 66; died, April 15, of cerebral hemorrhage.

**Raymond Johnson,** Worthington, Ind.; Indiana University School of Medicine, Indianapolis, 1916; aged 42; died, March 30, in the Freeman Greene County Hospital, Linton, of uremia.

**Elisha Sheperd Boland,** Boston; Medical College of Ohio, Cincinnati, 1877; an affiliate Fellow of the American Medical Association; aged 81; died, April 7, of chronic endocarditis.

**James Edwin Mead,** Detroit; Detroit College of Medicine, 1899; member of the Michigan State Medical Society; aged 58; died, April 17, in Traverse City, Mich., of pneumonia.

**Sanford Lammie Givan,** Spring Lick, Ky.; University of Louisville School of Medicine, 1893; formerly member of the state legislature; aged 74; died, April 2, of heart disease.

**George Pendleton Dale** ⊕ Dayton, Ohio; Miami Medical College, Cincinnati, 1900; aged 58; for many years on the staff of the Miami Valley Hospital, where he died, March 20.

**Arden Thomas McKinney,** Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1909; member of the Arkansas Medical Society; aged 51; died, March 17.

**Denwood Nowal Livingston Newbury,** Spokane, Wash.; Columbia University College of Physicians and Surgeons, New York, 1896; aged 65; died, January 31, of heart disease.

**Andrew C. Biehn** ⊕ Quakertown, Pa.; Jefferson Medical College of Philadelphia, 1893; on the staff of the Quakertown Hospital; aged 63; died, April 11, of secondary anemia.

**Lewis C. Knapp** ⊕ Monroe, Mich.; University of Michigan Medical School, Ann Arbor, 1891; aged 64; died, in April, at the University Hospital, Ann Arbor, of pneumonia.

**Michael F. McMeel,** Clinton, Iowa; College of Physicians and Surgeons, Keokuk, 1893; formerly county coroner; aged 63; died, April 10, of acute dilatation of the heart.

**Calvin R. Johnson,** Eminence, Ky.; Miami Medical College, Cincinnati, 1877; for many years member of the board of education; aged 77; died, April 3, of pneumonia.

**Joseph P. Craney,** Denver; Medico-Chirurgical College of Philadelphia, 1902; member of the Colorado State Medical Society; aged 56; died, April 8, of heart disease.

**Abraham Lincoln Cothran** ⊕ San Jose, Calif.; University of California Medical Department, San Francisco, 1893; aged 66; died, February 23, in the San Jose Hospital.

**William Harter McGrew,** La Fontaine, Ind.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1872; aged 84; died, March 30, of bronchopneumonia.

**William L. Wallace,** Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1896; member of the Tennessee State Medical Association; aged 63; died, March 13.

**Merrill Maitland Myers,** Des Moines, Iowa; Rush Medical College, Chicago, 1918; member of the Iowa State Medical Society; aged 40; was drowned, March 26.

**Joseph Rothkowitz,** New York; Cornell University Medical College, New York, 1906; aged 47; died, March 25, of coronary thrombosis and angina pectoris.

**Arthur A. Woods,** Los Angeles; Miami Medical College, Cincinnati, 1876; formerly health officer of Erie, Pa.; aged 76; died, April 12, of bronchopneumonia.

**William Porter Fears,** Lufkin, Texas; University of Louisiana Medical Department, New Orleans, 1870; Civil War veteran; aged 88; died, March 18.

**James Gratton Kennedy,** Elk City, Kan.; Jenner Medical College, Chicago, 1898; served during the World War; aged 67; died, March 29, of pneumonia.

**John C. Owens,** Plainfield, Ill.; Syracuse University College of Medicine, 1881; aged 75; died, April 2, in Detroit, of diabetes mellitus and myocarditis.

**Annie May Cheney Spofford,** Batavia, N. Y.; University of Buffalo School of Medicine, 1898; aged 58; died, April 11, in St. Jerome's Hospital, of uremia.

**James Weston Miller,** Santa Paula, Calif.; Rush Medical College, Chicago, 1884; aged 73; died, in March, of chronic interstitial nephritis and uremia.

**Earl Chalmers Ford,** Knoxville, Tenn.; University of Louisville (Ky.) School of Medicine, 1919; aged 42; died, April 12, of heart disease.

**Lewis E. McBride,** Franklin, Pa.; Chicago Homeopathic Medical College, 1895; on the staff of the Franklin Hospital; aged 62; died, March 15.

**Edgar Melville Hatton,** Orlando, Fla.; Starling Medical College, Columbus, 1892; aged 80; died, March 20, in a local hospital, of nephritis.

**A. A. Maynard,** Kerr, N. C.; College of Physicians and Surgeons, Baltimore, 1885; aged 72; died, April 4, in a hospital at Fayetteville.

**William J. Grimes,** East Liverpool, Ohio; Starling Medical College, Columbus, 1886; aged 74; died, March 31, of cerebral hemorrhage.

**Dickerson H. Welling,** Worthington, Ohio; Eclectic Medical Institute, Cincinnati, 1878; Civil War veteran; aged 84; died, March 18.

**James Henry Kimball,** Wakefield, Mass.; Harvard University Medical School, Boston, 1867; aged 87; died, March 30, of arteriosclerosis.

**John Cantrell Bynum,** Mountain View, Calif.; College of Physicians and Surgeons of St. Joseph, Mo., 1880; aged 84; died, February 23.

**Samuel Ross Miller,** Bismarck, Ill.; Rush Medical College, Chicago, 1878; aged 82; died, March 20, in La Fera, Texas, of senility.

**David E. Hills,** Fife Lake, Mich.; Detroit College of Medicine, 1900; postmaster; aged 59; died, March 27, of cerebral hemorrhage.

**Sarah Ann Emery Allison,** Money Creek, Minn.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 89; died, March 15.

**Fred Arthur Cozad,** Powersville, Mo.; St. Louis College of Physicians and Surgeons, 1896; aged 57; died, March 20, of heart disease.

**Frank E. P'Pool,** Socorro, N. M.; University of Nashville (Tenn.) Medical Department, 1878; aged 76; died, March 7, of pneumonia.

**John Marshall Williamson,** San Francisco; University of California Medical Department, 1885; aged 70; died, April 2, of leukemia.

**Everett Douglas Rodgers,** Chicago; Miami Medical College, Cincinnati, 1884; aged 71; died, April 16, of chronic myocarditis.

**Richard Haehl,** Stuttgart, Germany; Hahnemann Medical College and Hospital of Philadelphia, 1898; aged 59; died, February 7.

**J. Romeo Gauthier,** McLennan, Alta., Canada; School of Medicine and Surgery of Montreal, Que., 1906; aged 49; died, in March.

**Adah Leona Collison** ⊕ Seattle; Woman's Medical College of Pennsylvania, Philadelphia, 1915; aged 59; died, March 4.

**Charles Atkinson Winans,** San Francisco; Bellevue Hospital Medical College, New York, 1888; aged 67; died, February 13.

**Frank D. Walsh,** Guelph, Ont., Canada; Bellevue Hospital Medical College, New York, 1890; aged 63; died, April 9.

**Peter Francis Gunster,** Amity, Ore.; Bellevue Hospital Medical College, New York, 1871; aged 84; died, January 22.

**Mary Weeks Burnett,** Los Angeles; Hahnemann Medical College and Hospital, Chicago, 1879; aged 89; died, February 12.

**William H. Krieger,** Dayton, Ky.; American Eclectic Medical College, Cincinnati, 1887; aged 85; died in March.

**John Lynn Pratt,** Milford, Del.; Jefferson Medical College of Philadelphia, 1894; aged 68; died, March 14.

**George E. Dienst,** Aurora, Ill.; National Medical College, Chicago, 1898; aged 74; died, April 10, of senility.

**Hugh Thomas Walker,** Riceville, Iowa; Rush Medical College, Chicago, 1889; aged 82; died, March 10.

**Alexander Gilfillen,** Russellville, Ohio; Medical College of Ohio, Cincinnati, 1876; aged 81; died, March 15.

**Elisha Bishop,** Turners Station, Ky.; Miami Medical College, Cincinnati, 1879; aged 83; died, March 17.

**Andrew Crawford,** Scottsbluff, Neb.; Omaha Medical College, 1888; aged 80; died, February 14.

## NITROUS OXIDE-OXYGEN-ETHER EXPLOSION

*To the Editor:*—The article by Dr. Carl R. Steinke on this subject (The Journal, April 9, p. 1267) interests me because of the deductions drawn from the explosion occurring, Nov. 11, 1926.

"This particular explosion might have been due to sparks resulting from discharges of static electricity. However, it is believed there was a small leak in the breathing tube." Competent anesthetists know that ether-oxygen mixtures, especially when enclosed, are explosive. There is always exhalation of ether and oxygen (with ethylene or nitrous oxide, if added) through an exhaling valve in all anesthetics, and intelligent prevention of such accidents will not be found in the periodic inspection of all electrical equipment or gas machines but in the use of common sense. Such anesthesia should never be used in the presence of electrical equipment. There is no field for ether enclosed anesthesia in an x-ray room at any time. The best is nitrous oxide only.

W. V. Chalmers-Francis, M.D., Los Angeles.
Chief of Anesthetists' Staff, Hospital
of the Good Samaritan.

## STERILIZATION OF FABRICS IN HOSPITALS

*To the Editor:*—I have read with considerable interest an article entitled "The Importance of More Adequate Sterilization Processes in Hospitals" by Dr. Walter E. Dandy and published in the *Bulletin of the American College of Surgeons* (**16**:11 [March] 1932).

Permit me to call attention to the following statement, printed in italics, in his contribution: "Sterilization for one hour under a constant pressure of not less than twenty pounds is therefore the minimum that will assure destruction of all organisms." Later he states that every sterilizer should be equipped with two instruments, one for recording the time and the temperature of the chamber of the sterilizer during the entire period of sterilization, and the other one for recording the pressure curve during the entire period of sterilization. The latter statement, concerning temperature, is the one which might better have been put in italics.

It is a common fallacy, which has been perpetuated by the manufacturers of sterilizers, that the pressure within the sterilizer is the criterion by which the efficacy of the sterilizing process should be measured. It is obviously possible to have a pressure of a thousand pounds and have no sterilization result because the temperature might be at zero. The pressure in the sterilizer is simply used to cause a higher temperature by the compression of live steam.

The great danger in steam sterilization is that the steam admitted to the chamber may not be 100 per cent steam but may be mixed with air. Under these conditions, one may obtain the required pressure without obtaining the required temperature. In order to have a sterilizer filled with pure steam, it is necessary either to exhaust the chamber as many as five or six times during the sterilization or to have the sterilizer equipped with an automatic device for eliminating air and water of condensation. While it is true that a satisfactory temperature will not be reached unless from 17 to 20 pounds of pressure is applied to the sterilizer, the pressure of itself is of no significance. The latest type of bacteriologic sterilizers are equipped with thermometers, and it is unfortunate that pressure gages were ever provided for hospital sterilizers except to indicate the safety point for the steam pressure. It is obvious, therefore, that a record of the pressure curve is without significance, for the record of the temperature curve is all that is important.

As a matter of fact, the arbitrary period of one hour of sterilization, in practice in the Mayo Clinic for years, is really unnecessary if the sterilizers have been properly packed, and it is equally true that it is possible to pack a sterilizer in such a way that even an hour will be insufficient time for sterilization. The important point in hospital sterilization is that an adequately trained, conscientious supervisor should see to it that each item going into the operating room has been carefully and conscientiously sterilized and that at *irregular* intervals bacteriologic supervision is given to operating room equipment. Even these precautions will not take care of the many personal factors introduced into an operation by the surgeon and his assistants, and the practice of the most ideal methods of sterilization will not relieve the surgeon of the responsibility which he personally has in protecting his patient against operating room infections.

T. B. Magath, M.D., Rochester, Minn.

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

## PROGNOSIS AND TREATMENT IN NEPHRITIS

*To the Editor.*—During my third year of medical school I had scarlet fever and was in a hospital for contagious diseases under a regimen of rest and diet for six weeks. I now have a considerable amount of albumin in my urine, plus hyaline casts. My blood pressure is 140 systolic and 90 diastolic. My heart is normal in size but the pulse rate is 85 while at rest. There is a moderate amount of nocturia, averaging once during the night. There has been no edema or any other signs or symptoms. I am 29, 6 feet 2 inches (188 cm.) in height, and weigh 225 pounds (102 Kg.). I seem to be in perfect health but have been recently turned down by the government because of my urinalysis and blood pressure. I should like to know what my prognosis is as regards length of life, first, with a normal everyday average diet; second, with a protein poor and salt poor diet; third, with a very strict nephritis diet. Please advise me what functional tests are necessary to a further study of my condition. Please omit name.

M.D., California.

Answer.—The type of nephritis here described seems to be acute glomerulonephritis. Not many of these cases become chronic, complete recovery in the greater number occurring in the course of several months. If scarlet fever occurred recently, the prognosis for recovery is good. A blood pressure of 140 systolic is hypertension in a young person. The most important factors in treatment demand a certain amount of rest daily, preferably after meals, and abstinence from more than the ordinary strain of everyday life. Exercise beyond short walks should not be indulged in at this time. There is no necessity for protein restriction unless the nonprotein nitrogen of the blood exceeds 50 mg. per hundred cubic centimeters of blood. Even under these circumstances there should be only a slight reduction in protein intake. In fact, when a large amount of albumin is passed, it is often advisable to increase the protein intake. However, for one of this weight a restriction in the total intake of food leading to a loss of weight is to be recommended. Recent work by various investigators has shown that a salt free diet has its place in nephritis with edema and myocardial insufficiency, but not in glomerulonephritis. A low salt intake is preferable. As bouillons, spices and condiments are generally quite salty, and act mainly as stimulants to the appetite, they should be avoided.

There are two relatively simple tests of functional activity of the kidney, the one an estimation of the nonprotein nitrogen of the blood, already mentioned, and the other a urinary concentration test. The latter may be carried out in several ways. The method recommended here has the advantage of combining a dry and a wet period. No food or fluid is taken after dinner at 6 p. m. Urine thereafter is collected in separate containers until 10 o'clock the following morning, at which time from 1,000 to 1,500 cc. of water is taken. The urine is again collected for several hours in separate containers. The small quantities with higher specific gravities, reaching to 1.028 or 1.030, are obtained in the night and morning. Following the intake of the water, amounts reaching to 300 or 400 cc. with a specific gravity as low as 1.005 are not uncommon. With impaired renal function there is a tendency toward fixation of specific gravity and amount of urine passed during the whole period. This test may be combined with the administration of phenolsulphonphthalein at the time of the intake of the water. A more complicated test is the one of measurement of urea concentration. A description of this can be found in Addis's recent book on nephritis or in any other recent textbook.

### ECZEMATOID ERUPTION OF FINGERS

*To the Editor:*—I have a patient, an unmarried woman, aged 27, who has seen many noted physicians for a peculiar eruption of the fingers. It begins on the palmar surface and extends almost to the fingernail. There is no itching but there is a scaling of the surface. It begins as blisters and ends in scales. The patient is a typist and had to quit once because of soreness. She had spots of alopecia of the head and last September began with amenorrhea, which lasted until the latter part of December. The treatment I gave her was anterior pituitary, 1 cc., two times a week and solution of pituitary, 1 cc., once a week. After the second dose she menstruated normally and has since. The condition of the fingers has practically cleared up. The spots of alopecia are covered with hair, but this week she has had a relapse and the eruption is worse than ever. The patient should have menstruated two days ago but has not done so. The physical condition is otherwise normal. Can you give me any suggestions? Treatments first began about Dec. 15, 1931.

M.D., California.

Answer.—The eruption on the fingers has nothing to do with the endocrine disturbance except secondarily. It is probably an eczematoid ringworm, a dermatitis venenata from something in the environment, or an eczema. In any of these cases the improvement consequent to the endocrine therapy may have had something to do with clearing up the skin. The recurrence may be due to the fact that the patient has again touched something to which she is sensitized, to some change in the relation between the ringworm and its environment, or to lowered resistance on her part. The roofs of some of the vesicles should be searched for a fungus in 10 per cent potassium hydroxide solution, the slide being kept in a humidor and examined repeatedly for seventy-two hours before the search is given up. If a fungus is found, treatment should be given with mild Whitfield ointment, 2 or 3 per cent salicylic acid, twice as much benzoic acid, and ointment of rose water to make 100 per cent, applied at night and as often as possible during the daytime. If no ringworm infection can be found in the fingers but it is present between the toes, the Whitfield ointment can be tried cautiously, being used at first for several hours before retiring, to guard against irritation while the patient is asleep. If no proof of fungous infection is found, crude coal tar and zinc oxide, 6 per cent of each in petrolatum, may be tried. This is applied at night, cotton gloves being worn over it. The ointment should be removed in the morning with oil or with ointment of rose water. Soap should be avoided as much as possible. As the eruption improves, zinc oxide ointment should be alternated with the tar ointment. If the latter gets on the clothing, the spot should be soaked in oil or kerosene before washing.

### POSSIBLE ANGINA PECTORIS FOLLOWING SHOCK OF EXPLOSION

*To the Editor:*—A man, aged 55, apparently well, was standing on the sidewalk when an explosion in the street some 25 feet distant occurred. He was knocked down by the force of the explosion and was not struck by any object. He was taken to the office of a physician, where a condition similar to, or identical with, angina pectoris developed. Five weeks later he died with this cardiac pain. Is angina pectoris ever of traumatic origin, and what is the probable cause of death when a patient dies under circumstances similar to those in this case, violence being produced by what may be termed indirection? Any assistance along this line would be appreciated.

Edwin B. Walston, M.D., Des Moines, Iowa.

Answer.—Anginal pain is considered by the majority of observers to be due to an ischemia of the heart muscle. This deficiency in blood supply could be due to a thrombosis or an embolus obstructing a coronary vessel, anatomic changes in the walls of the coronary vessels, or to vasoconstriction of the coronary vessels.

Information is lacking as to just what biochemical factors predispose to thrombosis. There is some reason to think that anatomic nervous impulses can change the ratio of the various salts and proteins of the blood. Any theory, however, explaining why the sudden shock should cause changes resulting in a coronary thrombosis would be more ingenious than scientific. The same applies to an embolus, which has also the law of probability against it.

A coronary vasoconstriction has been assumed to result reflexly from other pathologic conditions in the chest, as when anginal attacks have followed on a bullet wound of the mediastinum with a bullet embedded there, or mediastinal tumors. Here there was no actual trauma.

A fall in blood pressure might reduce the coronary flow sufficiently to cause pain, in cases predisposed by pathologic changes in the coronary vessels.

Reflex vasoconstriction from nervous or emotional causes has never been actually proved, but there is abundant clinical evidence suggesting that fright, excitement, anger, worry or any emotion can cause such a vasoconstriction. A vasoconstriction could supposedly result in sufficient ischemia to cause a ventricular fibrillation and death.

Any explanation cannot be more than theoretical and unsatisfactory in the light of present knowledge.

### SENSITIVITY TO PRIMROSE

*To the Editor:*—Many florists who handle or grow primrose develop a sensitiveness and marked swelling resembling urticaria. This becomes troublesome and some patients cannot enter the greenhouse without having this troublesome condition. I understand that the primrose (Primula obconica) is the only plant which causes this. Can you give me any data as to the treatment? Has a vaccine been prepared for this condition such as one for poison ivy?

Howard O. Smith, M.D., Marlin, Texas.

Answer.—Hypersensitiveness to primrose is common, especially among florists, and it has been conclusively demonstrated that the resultant dermatitis can come either from contact with primrose or by being close to it, without actual contact. The offending substance is in the air nearby. The primrose is not the only plant that can cause this type of dermatitis (contact dermatitis); it can also be caused by poison ivy (Toxicodendron radicans), sumach, poison oak, pollen oil (ragweeds, grasses), chrysanthemum and tulip. The best treatment for the condition is avoidance, and symptomatic lotions for the urticaria when it occurs. Wearing rubber gloves while handling primroses should help to some extent. There is apparently nothing in the literature regarding treatment by injections of primrose extract such as is used in poison ivy cases which ameliorates the effects but does not prevent them. Bloch (*Arch. f. Dermat. u. Syph.* **162**:349, 1930) has done more work on primrose sensitiveness than any one else and has shown that most human beings (and rats and guinea-pigs) can be made hypersensitive to primrose by repeated painting of an extract on the skin, and they seem to remain hypersensitive. The oily residue of all these plants is the offending factor.

### BLOOD PRESSURE DANGERS

*To the Editor:*—I recently read the statement, as an authoritative dictum, that a blood pressure above 160 at any age is dangerous. Is this generally accepted as a fact by the profession at present? My own observation has been that people with essential hypertension ranging from 160 to 200, especially when the diastolic pressure is in the nineties, frequently have years of comfortable and useful life ahead of them. Also, I have noted that 50 per cent of my cases of cerebral hemorrhage and angina occur in people with so-called normal blood pressure. Please enlighten me. Kindly omit name.

M.D., Illinois.

Answer.—Blood pressure levels above 160 systolic are abnormal but not strictly dangerous. Such patients should be studied at regular intervals, particularly from the standpoint of their cardiovascular renal system.

Repeated clinical observations extending over a period of twenty years corroborate the view that individuals with high systolic and relatively low diastolic pressures may go on symptom free for many years.

Cerebral accidents and angina pectoris occur in the absence of hypertension, and even when the blood pressure is below normal. This, however, is true in only about 25 per cent of the cases.

### NITROBENZENE

*To the Editor:*—What is the toxicity of nitrobenzene (oil of mirbane)? Would it be a hazard if used in open containers and agitated in a closed room? May an individual working with nitrobenzene be examined periodically in any way to determine any untoward effects? Please omit name.

M.D., Indiana.

Answer.—Nitrobenzene (nitrobenzol, oil of mirbane) acts on the human body much like aniline (aminobenzene). Entry into the body is more often through the skin, so that intoxications are likely to be regarded as accidents rather than as occupational diseases. Inhalation of the dust or fumes containing nitrobenzene may lead to poisoning; acute and chronic forms are recognized together with local burns of the skin.

In acute and severe cases, manifestations center about the formation of methemoglobin, cyanosis, collapse, and respiratory failure. The mildest degree of poisoning is characterized by gastro-intestinal upsets, headache, dizziness, malaise, and burning of the skin. Chronic involvements may disclose some or all of the following symptoms: anxiety states, disturbances in sensation and coordination, hyperreflexia, visual impairments, cyanosis, profound changes in the cellular elements of the blood, anemia, hematin in the urine, skin eruptions, respiratory embarrassment, and an odor of bitter almonds on the breath.

All workers in nitrobenzene should be given physical examinations at frequent intervals, but exclusive reliance should not be placed on specific tests such as for hematoporphyrin, hematin and methemoglobin, or on the odor of breath. Further information on this highly toxic agent may be found in the International Labour Office's Occupation and Health, and "Industrial Health," by Kober and Hayhurst.

### CROSS AGGLUTINATION TESTS BEFORE TRANSFUSION

*To the Editor:*—Could you kindly inform me whether in blood transfusion work cross agglutination is sufficient without typing? That is, if the cells of the blood of the prospective donor and the recipient do not cause agglutination with the serum of the other, is it perfectly safe to transfuse without preliminary typing? This would obviously make it unnecessary to keep known type serums on hand. Please omit name.

M.D., New York.

Answer.—In tests for blood transfusion, cross agglutination is sufficient without preliminary grouping of the bloods. For example, if the serum of the recipient (patient) does not agglutinate the red blood cells of the prospective donor, nor the serum of this donor agglutinate the red blood cells of the recipient, the two bloods are considered to be of the same group and compatible. It is considered comparatively safe to transfuse if the red blood cells of the prospective donor are not agglutinated by the serum of the recipient; hence the use of blood from universal donors by many operators. Preliminary typing, especially when the recipient's blood group is one of the less common, often makes it possible to locate a satisfactory donor more readily.

### THE SENSES OF MAN

*To the Editor:*—Will you kindly tell me whether more than five senses are considered? Also the order in which they come. Please omit name.

M.D., California.

Answer.—A greater number of sensations are now recognized than those enumerated in the stereotyped textbooks of a generation ago. Incidentally, it is not possible to evaluate their importance by stating that they should "come" in a specific "order" of significance and/or indispensability. For that reason, the various sensations will be mentioned as they might occur to one:

1. Sight: light and form; color.
2. Taste.
3. Touch: deformation of the skin, tickle and vibration sense, and the deep sensibility of muscle.
4. Temperature: heat and cold.
5. Smell.
6. Proprioceptive stimuli from the muscles, tendons, and joints informing the organism of location in space.
7. Changes in position in space through the functional activity of the semicircular canals, utricle and saccule.
8. Hearing.
9. Pain from skin, muscle and blood vessels.
10. Visceroceptive stimuli of which persons are usually unconscious but which probably affect vasomotor, respiratory and cardiac changes reflexly; e. g., the inhibition of respiration from distention of the lungs.

### BOTULISM AND RIPE OLIVES

*To the Editor:*—In 1919 Dr. Charles Armstrong (*Public Health Reports* **34:**2877 [Dec. 19] 1919) published an article on the subject of botulism from eating canned ripe olives. Can you tell me whether there has been a serious epidemic of botulism in the country since that time, and can you also give me any reason for the fact that ripe olives are generally considered to be much more dangerous in this regard than green olives? In addition, will you tell me what other foods than olives have been responsible for outbreaks of botulism?

G. Henry Knoll, M.D., Le Roy, N. Y.

Answer.—The last outbreak of botulism from commercially processed ripe olives occurred in August, 1924, in Los Angeles. The last outbreak of botulism from commercially canned foods of any character occurred in October, 1925, in Hanna, Wyo., from potted meats.

There have occurred, however, many outbreaks, some of serious character, involving a number of cases and a number of deaths from materials packed in the home by various unsafe processes.

Ripe olives are not more dangerous than other foods of like character; in fact, they are less dangerous. The spore of Bacillus botulinus is selective as to the medium in which it grows. Likewise it is sensitive to the chemical reaction of the food which it may have contaminated in the preparation of or in the process of canning. For instance, any vegetable that has a $p_H$ around neutral, which is classified on the $p_H$ scale as 7.2, should always be processed with heat high enough to kill the spore of B. botulinus, as this is the optimal reaction for its growth. Furthermore, the spores of B. botulinus do not ordinarily grow in material that is not packed under vacuum. Green olives not being so packed and with a high salt content, and therefore decidedly alkaline, have always been regarded as safe.

Of course, any canned food that has not been processed at sufficient temperature, and this holds true for home canned foods of all character, except those preserved with sugar or with salt, should be heated for a number of minutes before being served, since the poison produced by B. botulinus in its growth is easily killed at boiling temperatures at sea level. Paradoxically, the spore of the organism is difficult to destroy at boiling temperature.

### PERNICIOUS ANEMIA

*To the Editor:*—I should like to know whether the statistics as to the permanence of cure in pernicious anemia are available. If they are, I should like to know where I might find them.

J. L. Garey, M.D., Catonsville, Md.

Answer.—Since there is no such thing as cure in pernicious anemia so far as is known, there could hardly be any statistics available.

If the question means the relief of symptoms to a greater or lesser extent, the facts are also difficult to obtain at this time since efficient treatment of the disease has been available for only about six years. It seems likely that the vast majority of individuals can be maintained in good health by the adequate treatment of the disease. The most serious complication, usually the result of taking inadequate amounts of potent material, is the development of symptoms referable to the central nervous system. Of course, patients with pernicious anemia have died during adequate treatment from unrelated causes. The use of liver extract in pernicious anemia is somewhat analogous to the use of insulin in diabetes and is not to be regarded any more than is insulin as a specific cure for the condition.

The paper by Beebe and Lewis on the maintenance dose of potent material in pernicious anemia (*Am. J. M. Sc.* **181:**796 [June] 1931) will perhaps serve to answer the question as well as any single contribution to this subject could, in the absence of available statistics.

### SUSCEPTIBILITY TO FRACTURE

*To the Editor:*—Can you suggest treatment for a case showing abnormal susceptibility to fractures? The patient is a boy, aged 15 years, who has had seven fractures in the past six years, five of them fractures of the femur. The last occurred a few days ago when he stepped off of a low porch. The fractures always heal readily and always occur at different points.

C. S. Neer, M.D., Vinita, Okla.

Answer.—For fragitalis osseum and osteogenesis imperfecta, the following references are apropos:

Corshner, R. G.: *Am. J. Roentgenol.* **16:**405 (March) 1926.
Key, J. A.: *Arch. Surg.* **13:**523 (Oct.) 1926.
Scott, C. R.: *Am. J. Roentgenol.* **12:**237 (Sept.) 1924.

Concerning the treatment, the following should be beneficial:

1. Cod liver oil.
2. Calcium in any of the recognized forms.
3. Ultraviolet radiation.
4. Foods such as are given to prevent and correct nutritional disturbances exemplified by rickets.
5. Special exercises both on land and under water, and massage of the muscles generally in order to improve their tonicity.

### SUPERSTITIONS REGARDING THE HAIR

*To the Editor:*—Will you please give me some information regarding the cutting of children's hair. I am occasionally asked whether scanty hair in a girl will grow thicker and more healthy if it is regularly cut; also whether the cutting of a good growth of long hair will injure it so that subsequently it will not be so good as before. I know of no scientific answers to such questions, and should be glad to have your opinion. Kindly omit name.

M.D., Michigan.

Answer.—These two popular notions check each other admirably. One is as true as the other. Hair is composed of a horny substance, has no circulation, and grows only from the papilla at its base, a separate structure. Cutting the hair at any point has no effect whatever, good or bad, on its growth. Brushing is the best method of stimulating the circulation of the scalp and therefore the growth of hair.

### TREATMENT OF PROSTATITIS

*To the Editor:*—A man, aged 64, in good physical condition, with a history of prostatitis, noticed about eight months ago blood in his semen (following coitus). I started to treat him three months ago. There was no nycturia, the stream was good, the prostate was tender and not enlarged, and the seminal vesicles were somewhat enlarged and tender. In prostatic secretion on expression there were leukocytes and bacilli but no blood. He took about fifteen treatments consisting of diathermy plus intravenous injection of sodium iodide (20:200), also six injections intramuscularly of a milk protein preparation plus diathermy, each treatment followed by massage of the prostate. The pains in the back and over the bladder disappeared after a few treatments; also the visible blood from the semen. But the latter is still rosy colored, showing erythrocytes under the microscope. The urine is normal. The Wassermann reaction is negative. I am figuring on giving him mercurochrome-220 soluble intravenously. What do you suggest to clear up this condition? Please omit name.

M.D., Indiana.

Answer.—The improvement following the treatments reported points to a chronic inflammation apparently excluding a malignant condition. Autohemotherapy will often succeed in cleaning up the remaining symptoms. The routine is to aspirate about 10 cc. out of a superficial vein and immediately inject this quantity of blood into the gluteus muscle. These injections are repeated at short intervals until a definite result occurs. It is not quite evident what mercurochrome should accomplish in such instances. However, *it must be kept in mind* that intravenous injections of mercurochrome solutions always involve the danger of severe renal disturbances, such an occurrence probably outweighing any possible benefit that could be derived from such medication. Conditions as reported always call for an extensive period of combined treatments.

### EFFECT OF FALL IN CASE OF PLACENTA PRAEVIA

*To the Editor:*—Could you send me information on the effects that a fall might have on mother and baby in a case of central placenta praevia, the fall occurring three weeks before delivery, the mother going one week over her term? A woman with central placenta praevia died an hour after delivery through the placenta by version. It is claimed that a fall which she had three weeks prior to her death probably caused her death. I did not know about the fall until the morning of delivery.

M.D., Ohio.

Answer.—There is no available literature on the problem as stated. A parous woman who has a placenta praevia may bleed profusely following a fall. This is due to a loosening of the insecurely attached placenta. If, however, no bleeding resulted following the fall, and the patient went three weeks further until delivery, the maternal or fetal death can hardly be ascribed to the fall. Any trauma sustained by the fall would result in bleeding and immediate injury to mother and fetus through loss of blood.

### PATHOLOGY OF INJURY TO HAND

*To the Editor.*—A man, aged 48, was cranking an automobile when a backfire caused the right hand to be thrown against the fender, striking the middle of the posterior surface of the proximal phalanx of the fifth finger. The skin was broken and there was moderate hemorrhage. The bone was not broken and prompt healing of the skin wound occurred; but a few days after the accident it was noted that the distal phalanx of the fifth finger could not be extended. Six weeks later this condition remains the same. There is no pain or soreness and all other motion is normal, but voluntary extension of the distal phalanx is still impossible. There is loss of tactile sensation in the skin over the posterior portion of the distal and second phalanges. Sensation over the flexor surface is normal. Please discuss pathology. Please omit name.

M.D., Oregon.

Answer.—The patient doubtless sustained a cutting injury with division of the extensor tendons of the fifth finger—the extensor communis digitorum and extensor digiti quinti. The two dorsal digital branches of the ulnar nerve, one of which lies on each side of the dorsum of the fifth finger, may have been divided or crushed. In either case there would be loss of sensation on the dorsum of the finger distal to the site of injury.

### TROPICAL AMNESIA OR "COAST MEMORY"

*To the Editor:*—In Queries and Minor Notes (The Journal, March 19, p. 1019), I believe that you have not fully answered the question asked by M.D., East Africa; therefore I take the liberty of adding my opinion. The condition to which your inquirer refers is said to occur in Africa, mainly on the west coast, and is known as tropical amnesia, or coast memory. It is occasionally found in white persons after sojourning in the tropics several years without being able to make proper adjustments to conditions of living or to the climate. There is reason to believe that the circumscribed amnesia is hysterical in nature, but I do not know whether it actually is. The description of the case given in the query fits in with what little I know of tropical amnesia. Treatment consists of removal from the tropics.

I. S. Wechsler, M.D., New York.

## COMING EXAMINATIONS

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

California: *Reciprocity.* Los Angeles and San Francisco, June 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Connecticut: *Basic Science.* New Haven, June 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

Delaware: Wilmington, June 14-16. Sec., Dr. Harold L. Springer, 1013 Washington St., Wilmington.

District of Columbia: *Basic Science.* Washington, June 29-30. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Florida: Tampa, June 13-14. Sec., Dr. W. M. Rowlett, 812 Citizens Bank Bldg., Tampa.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Indiana: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

Iowa: Iowa City, June 7-9. Dir., Mr. H. W. Grefe, Capitol Building, Des Moines.

Kansas: Kansas City, June 21-22. Sec., Dr. C. H. Ewing, Larned.

Kentucky: Louisville, June 8-10. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.

Maryland: *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore. *Regular.* Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

Michigan: Ann Arbor and Detroit, June 7-9. Sec., Dr. Nelson McLaughlin, 1010 Maccabee Bldg., Detroit.

Missouri: St. Louis, June 14-16. Sec., Dr. James Stewart, Capitol Bldg., Jefferson City.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

Nebraska: *Regular.* Omaha, June 9-11. Dir., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Room 315, State Education Bldg., Albany.

North Carolina: Raleigh, June 20. Sec., Dr. John W. MacConnell, Davidson.

Ohio: Columbus, June 7-10. Sec., Dr. H. M. Platter, 85 E. Gay St., Columbus.

Oklahoma: Oklahoma City, June 8-10. Sec., Dr. J. M. Byrum, Shawnee.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Texas: Marlin, June 21-23. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

Vermont: Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 15-18. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

Wyoming: Cheyenne, June 6. Sec., Dr. W. H. Hassed, Capitol Bldg., Cheyenne.

## District of Columbia January Report

Dr. W. C. Fowler, secretary, Commission on Licensure, reports the written examination held at Washington, Jan. 11-12, 1932. The examination covered 6 subjects and included 70 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, all of whom passed. The following colleges were represented:

PASSED

| College | Year Grad. | Per Cent |
|---|---|---|
| University of Arkansas School of Medicine | (1930) | 83.5 |
| Georgetown University School of Medicine | (1929) | 83.1, (1930) 79.3, 81.5, 83.9 |
| George Washington University School of Medicine | (1930) | 77.8, 86.4 |
| Howard University College of Medicine | (1930) | 79.6 |
| Northwestern University Medical School | (1929) | 86.8 |
| Indiana University School of Medicine | (1927) | 81.1 |
| Columbia University College of Phys. and Surgs. | (1921) | 83.3, (1930) 86.1 |
| Medical College of Virginia | (1930) | 85.6 |
| University of Virginia Department of Medicine | (1929) | 83.4, 88.4 |

## Ohio Reciprocity Report

Dr. H. M. Platter, secretary, Ohio State Medical Board, reports 15 physicians licensed by reciprocity with other states and two physicians licensed by endorsement, Jan. 5, 1932. The following colleges were represented:

LICENSED BY RECIPROCITY

| College | Year Grad. | Reciprocity with |
|---|---|---|
| University of Colorado School of Medicine | (1928) | Colorado |

# Book Notices

**The Practice of Dentistry and the Incomes of Dentists in Twenty States: 1929.** By Maurice Leven, Ph.D., of the Research Staff of the Committee on the Costs of Medical Care based upon data collected under the direction of Dorothy Fahs Beck, of the Research Staff of the Committee on the Study of Dental Practice of the American Dental Association. Publications of the Committee on the Study of Dental Practice of the American Dental Association, No. 1. Cloth. Price, $2. Pp. 224. Chicago: University of Chicago Press, 1932.

In this volume the author has assembled and analyzed a mass of data relative to dental practice not heretofore available. The study, which is the report of a questionnaire survey conducted by the American Dental Association, includes chapters dealing with professional aspects of practice, economic features of practice, the dentist's working year and the number of patients treated, charges for dental services, business practice, incomes by states and types of practice, location and income, year of graduation and income, salaried personnel and income, income as related to working time, and dental incomes and dental expenses.

From the study of the 5,544 reports received, it appears that fully 96 per cent of the dentists practicing at the time of the survey had had at least three years of training in a dental school. This includes about 38 per cent whose formal training extended over a period of four years. Three per cent of the dentists regard themselves as complete or limited specialists, while 8 per cent are partial specialists. In the chapter dealing with the economic features of dental practice, it appears that 53 per cent of all dentists employ salaried personnel of some kind. Approximately 70 per cent of all dentists have practiced in their respective communities throughout their entire professional career.

In 1929 the working year for more than two thirds of the dentists was forty-eight weeks, while about one fourth worked fifty weeks and 10 per cent practiced throughout the entire year. The normal week of the typical dentist consists of thirty hours at the chair, six hours in the laboratory, and ten hours at other office duties; the average dentist treated approximately eight patients daily in 1929 and came in contact with 430 different patients during the year. More than 80 per cent of dentists attempt to maintain an hourly charge of $5, but the great majority vary their fees for the same services.

Dentists' incomes are correlated with the degree of specialization, the 1929 arithmetical average for complete specialists being $15,000, for partial specialists $10,700, and for general practitioners $7,800. The corresponding averages for net income are approximately $8,600, $6,100 and $4,800.

Those who use the data contained in this study must constantly bear in mind that the figures represent incomes and volume of practice for 1929. Since that time, general economic conditions have appreciably affected both the dental and the medical profession, and while certain relative values may remain fairly constant, others must be corrected for the change in economic conditions in order to make them applicable to the present.

The study appears to have been carefully conducted and the text is ample to explain all statistical deductions. The volume should be useful not only to practicing dentists but also as a reference work in libraries, from which students contemplating the study of dentistry may derive many facts concerning the profession.

**Blood Sugar in Normal and Sick Children with Special Reference to Coeliac Disease.** By Elisabeth Svensgaard Acta Pædiatrica, Volume XII, Supplementum IV. Paper. Pp. 245. Copenhagen: Levin & Munksgaard, 1931.

Using the Hagedorn-Jensen method, the author first investigated the blood sugar in normal infants and children. In normal infants up to the first year of life she found that fasting blood sugar values were lower than the normal values for adults. After ingestion of dextrose, the duration of hyperglycemia in normal infants under a year of age is as a rule less than two and one-half hours. In normal older children the fasting blood sugar values approach closely the normal adult figures, although occasionally a great variation in an individual child may be found. Likewise the results obtained in older children after the ingestion of dextrose approximate the adult normals. Following these blood sugar investigations on normal infants and children, the author reports her results on the blood sugar determinations in children suffering with celiac disease, cretinism, eczema, rickets and tetany. In celiac disease she obtained only a slight degree of hyperglycemia after ingestion of dextrose in doses of from 1 to 2 Gm. per kilogram. This small rise in blood sugar after the ingestion of dextrose she considers a valuable diagnostic sign in celiac disease. In cretins she obtained a greater degree of hyperglycemia after the ingestion of dextrose after thyroid treatment was instituted. The thyroid treatment seems to have a marked effect on blood sugar regulation in cretins. Blood sugar determinations in infants and children suffering with eczema, rickets and tetany showed only slight variations from the normal values. These interesting observations on blood sugar determinations in normal and sick children should serve as a valuable guide to any one making similar or related studies. A complete bibliography and detailed protocol are attached at the end of the volume.

**Health and Hospital Survey, Kansas City, Missouri.** Made for the Chamber of Commerce of Kansas City under the direction of the Committee on Public Health and Welfare. Prepared by the Committee on Administrative Practice of the American Public Health Association and the Kansas City Public Service Institute. Paper. Price, $2. Pp. 328. Kansas City: Chamber of Commerce, 1931.

This survey was undertaken at the behest of the Public Health and Welfare Committee of the Chamber of Commerce of Kansas City, Mo., to determine in what respects the health work of the city might be adequate or inadequate and what steps should be taken to improve the service for the money expended. Fourteen different volunteer groups were carrying on health work in addition to various official agencies, resulting in duplication of efforts in some places and leaving gaps in others. The reported number of 127 cases of tuberculosis in 1929 is a record of which any city might be proud were it not for the fact that 306 residents died from that disease during the year, indicating that there existed from 1,500 to 2,700 cases of tuberculosis at the time. Other inconsistencies picture a rather confused state of public health activities—for instance under food control is grouped the control of rabies and under the guise of sanitation is found the cutting of weeds, a procedure that has a doubtful place in a health program. The report is divided into two parts. Part I is devoted to various health activities, such as vital statistics, communicable disease control, child hygiene, school hygiene, public health nursing, milk and food control, sanitation and laboratory service. Each item is discussed in the light of conditions as they actually exist as against the ideal, and at the end of the chapter practical suggestions are made. Every municipal health official will be interested because he will find parallels with recommended remedies to many of his problems. Part II, devoted to hospitals, is a study in medical economics. The twenty-one hospitals in Kansas City, Missouri, and five in Kansas City, Kansas, are surveyed in detail as to bed capacity, bed occupancy, types of cases admitted, financial data and medical, nursing, laboratory, occupational therapy, dental and social services connected with the hospitals, together with studies of outpatient and clinic facilities. Special chapters are devoted to the tax-supported hospitals which come under the supervision of the director of health.

**An Introduction to the Literature of Vertebrate Zoology Based Chiefly on the Titles in the Blacker Library of Zoology, the Emma Shearer Wood Library of Ornithology, the Bibliotheca Osleriana and Other Libraries of McGill University, Montreal.** Compiled and edited by Casey A. Wood, M.D., LL.D., Collaborator, Division of Birds, Smithsonian Institution. Cloth. Price, $15. Pp. 643. London: Oxford University Press, 1931.

This is a work by a bibliophile for fellow enthusiasts, and the printer has cooperated nobly. It is primarily a catalogue, but in a series of introductory chapters the compiler, as he modestly calls himself, takes a group of friends through the McGill libraries, shows them the greatest treasures, and incidentally reviews the history of vertebrate zoology by saying a few words about preeminent authors and remarkable books. His emphasis is on natural history and faunistic and systemic studies, but he touches on comparative anatomy and paleontology. The oriental literature referred to will be new to most zoologists. Attention is called to important periodicals and serials. There are two convenient classified indexes in which certain authors are grouped according to the classes of vertebrates they have considered and the areas they have covered.

**Protection of Women and Children in Soviet Russia.** By Alice Withrow Field. Cloth. Price, $3. Pp. 241. New York: E. P. Dutton & Company, Inc., 1932.

The author of this volume went to Russia to study the system used under the five year plan for the care of women and children. She presents the story of a government planned by men but leading essentially to a matriarchal empire. Beginning with a discussion of the program for the protection of women and children in Russia, she discusses the legal phases of women's rights, the customs regarding abortion and birth control, the consultation rooms established for women, prenatal examinations, maternity care and similar subjects. Of especial interest are the plans for the handling of children, which, obviously, have come under the greatest criticism because of their tendency to make the home secondary in family life. If plans continue as now in effect, the author believes all children will eventually come under complete control of the state. However, at present it seems unlikely, largely because of the present condition of finance, that the children will be taken from their parents except during the period when parents are at work. The final chapters of the book present various bulletins, pamphlets, charts and sheets of instruction for the control of women and children under the five year plan.

**Chirurgische Indikationen für Ärzte und Studierende.** Von Professor Dr. Karl Reschke, Oberarzt der chirurgischen Universitätsklinik Greifswald. 1. (Allgemeiner) Teil. Paper. Price, 22 marks. Pp. 357. Berlin: F. C. W. Vogel, 1932.

Textbooks of surgical technic are available in comparatively large numbers in various languages. To date there have been none pertaining to surgical indications. The answer to questions that arise in the presence of certain conditions may be found scattered through various textbooks on surgery and in special monographs but has never before been compiled in one volume. This the author attempts and accomplishes quite successfully. Based on personal experience as well as on an extensive review of the literature, this volume deals with the indications for conditions in general surgery. A section dealing with special surgery will appear at a later date. In this volume the author discusses at length and in detail such subjects as the different forms of anesthesia, treatment of wounds, acute and chronic infections, diseases of blood vessels and lymphatics, the various disorders of bones and joints, and tumors. The ideas expressed are adequate, detailed, and in keeping with the best modern thought. Although it contains nothing original or particularly new, this work is of distinct value to the student and young man in surgery and, being complete, may occasionally prove useful to the more experienced in the specialty.

**Orthopädische Therapie in der Allgemeinpraxis: Angeborene Deformitäten.** Von Hofrat Professor Dr. Hans Spitzy, Direktor und Primararzt des Orthopädischen Spitales in Wien. Therapie in Einzeldarstellungen: Wissenschaftliche Grundlagen und praktische Anwendung. Herausgegeben von Prof. Dr. R. von den Velden und Priv.-Doz. Dr. P. Wolff. Boards. Price, 7 marks. Pp. 115, with 77 illustrations. Leipzig: Georg Thieme, 1932.

The author of this small book is one of the two greatest orthopedic surgeons of Austria. He discusses congenital deformities. Practically every illustration is from his own observation. Torticollis, congenital elevation of the scapula and other deformities of the upper extremity are considered; also deformities of the lower extremity, including dislocation of the hip and other defects of the hip, knee, foot and vertebrae. There are short discussions on osteogenesis imperfecta, cartilaginous exostoses, pseudarthrosis, birth paralysis and spastic paralysis. The illustrations, which include photographs, line drawings and roentgenograms, are clear and effective. The book has been neatly published and is well worth the time spent in reading it.

**Gould's Medical Dictionary Containing the Words and Phrases Generally Used in Medicine and the Allied Sciences, with Their Definition, Pronunciation and Derivation.** By George M. Gould, A.M., M.D. Edited by R. J. E. Scott, M.A., B.C.L., M.D. Third edition. Fabrikoid. Price, $7.50. Pp. 1538, with illustrations and tables. Philadelphia: P. Blakiston's Son & Company, Inc., 1931.

This is a praiseworthy addition to the others of its kind now on the market. It has retained, for the most part, the salient features of the first two editions. Some changes are, however, immediately noticeable, as, for example, the inclusion of a large number of words which have only recently been incorporated into medical usage; the enlargement of the table of micro-organisms, for which this dictionary has always been justly noted, and the appended table of protozoa and metazoa and the infections that they cause. The striking feature of this dictionary is, as it has always been, the simplicity of its arrangement. Each item is defined in its proper place, instead of being carried over to some other place and being defined under a general group heading. In this way the editors avoid a burdensome system of cross-references, which generally serve only to confuse the average user. There are 173 tables in this edition, as against 170 in the last one. Mention should be made of the excellent quality of the paper used in this dictionary, as well as of the admirable printing and illustrations and the new stiff fabrikoid cover, a decided improvement over the old flexible one.

**Some Radium Cases at the Middlesex Hospital: A Photographic Record.** By A. Cameron MacLeod, M.B., B.S., F.R.C.S. Boards Price, 7/6. Pp. 154, with 122 illustrations. London: John Murray, 1931.

The purpose of this book is primarily to present a photographic record of a series of neoplasms treated with radium in the Middlesex Hospital. Only cases that lend themselves to photographic record are described and depicted. Photographs of epithelioma of the skin, lip and tongue are shown before and after radium treatments. The technic is described and the dose stated. The photographs clearly indicate effective irradiation of this group of tumors. Carcinoma of the breast was treated according to the method first described by Geoffrey Keynes. The photographs constitute a clear and effective demonstration of the results of radiation on surface cancer. The dosage may also serve as a general guide in interstitial irradiation of this group of neoplasms. The author has been more partial to interstitial irradiation, as for example in the treatment of cancer of the lip, which is best treated by the application of radium on the surface by means of a mold.

**Mental Healers: Franz Anton Mesmer, Mary Baker Eddy, Sigmund Freud.** By Stefan Zweig. Translated by Eden and Cedar Paul. Cloth. Price, $3.50. Pp. 363. New York: Viking Press, 1932.

The mental healers included in this extraordinary volume are Franz Mesmer, Mary Baker Eddy and Sigmund Freud. The life of Mesmer reveals the beginning of magnetic healing and the opening of the temple in Paris. It credits Puysegur for his fundamental observations as to the effects of the mind on the body. The life of Mrs. Eddy is a burning analysis of her career which follows the Dakin and Milmine contributions for fact and which shows the manner in which the Christian science group have exploited financially the followers of the high priestess of the Christian science cult. In this section of his book, Stefan Zweig ventures numerous aphorisms as to the features of the American character that directed the extraordinary development of Mrs. Eddy's group.

For the work of Signund Freud, Zweig has great admiration. He does not, of course, concern himself with the manner in which the freudian doctrines have been so terribly exploited by the disciples and imitators of the great psychologic master. He presents the personality of Freud in a vital manner and reveals the background of freudian philosophy. The concluding sentence is enlightening: "And while the experts are still disconcerted because his teaching cannot be satisfactorily pigeonholed and docketed as 'medicine' or 'natural science' or 'philosophy' but partakes of the nature of all, while professors and pundits and privy councilors are still wrangling about its details and its ultimate value, the teaching itself has long since made good and been established as irrefutable—as true in that creative sense which Goethe has made immortal in the words: 'The fruitful, that alone is true.'"

**The Lancet Commission on Nursing Appointed in December, 1930, to Inquire Into the Reasons for the Shortage of Candidates, Trained and Untrained, for Nursing the Sick in General and Special Hospitals Throughout the Country, and to Offer Suggestions for Making the Service More Attractive to Women Suitable for This Necessary Work.** Final Report. Paper. Price, 2s. 6d. Pp. 256. London: The Lancet, Ltd., 1932.

This is the final report of the committee appointed by the *Lancet* in 1930 "to inquire into the reasons for the shortage of candidates, trained and untrained, for nursing the sick in general and special hospitals throughout the country, and to offer suggestions for making the service more attractive to women suitable for this necessary work." The report includes the reasons which the committee found for the shortage of candidates. It offers suggestions as to how the number of desirable candidates might be increased. The report is based on a large amount of pertinent information, is well edited, and contains a number of tables and charts. It is valuable for all who are interested in the proper supply of nurses, whether in Great Britain or elsewhere.

**The Foundations of Medical History.** By Sir D'Arcy Power, K.B.E., F.R.C.S., Consulting Surgeon to St. Bartholomew's Hospital. Johns Hopkins University, Institute of the History of Medicine. Cloth. Price, $3. Pp. 182, with 3 illustrations. Baltimore: Williams & Wilkins Company, 1931.

This volume contains the six lectures delivered by the author at the Institute of the History of Medicine in Johns Hopkins University. The writings of Sir D'Arcy in the field of medical history are numerous and invariably interesting. The present series includes an account of St. Bartholomew's Hospital; also some studies of biography, bibliography and iconography. The final essay is entitled Aristotle's Masterpiece.

**La maladie de Hodgkin: Lymphadénie aleucémique. Lymphosarcome. Pseudo-leucémie de Bonfils. Morbus Hodgkini de Wilks. Adénie de Trousseau. Granulome malin de Benda. Lymphogranulome malin. Lymphogranulomatose maligne, etc.** Par Paul Chevallier, professeur agrégé à la Faculté de médecine de Paris, et Jean Bernard, intern des Hôpitaux de Paris. Paper. Price, 75 francs. Pp. 293, with 69 illustrations. Paris: Masson & Cie, 1932.

This volume considers the typical forms of Hodgkin's disease and will be followed by a volume dealing with variations. The available knowledge about Hodgkin's disease is presented in an interesting, orderly form, nothing original being presented. The controversial matter of etiology is discussed. There is some repetition in subject matter, but the book is well outlined and indexed. The bibliography is especially valuable for its reference to the French and the Italian literature.

**Kolloidreaktionen der Rückenmarkflüssigkeit (Technik, Klinik und Theorie).** Von Dr. med. Willy Schmitt, Privatdozent und Oberarzt der Medizin, Universitäts-Poliklinik, Leipzig. Paper. Price, 12.50 marks. Pp. 181, with 72 illustrations. Dresden: Theodor Steinkopff, 1932.

The study of cerebrospinal fluid has become so extensive in recent years that entire monographs have been written on a single phase of the subject. In this monograph the author reviews the colloidal reactions on cerebrospinal fluid, including Lange, mastic, benzoin, paraffin, shellac and sublimate fuchsin. A detailed description of the technic and an interpretation of every test is given. The author has added nothing original, but he has covered the subject in all its phases. His familiarity with the minutest details shows that he has had a great deal of experience with the various tests. This is not a book for the general practitioner, but it will be found of distinct value to the laboratory worker.

**The Genius of Louis Pasteur.** By Piers Compton. Cloth. Price, $4.50. Pp 361, with 8 illustrations. New York: Macmillan Company, 1932.

This biography of the great chemist who founded modern bacteriology is written simply and with understanding. It has not the brilliance of the book by Vallery-Radot nor is it as scientific as the contribution of Duclaux. It depends on these works for its facts, but neither in the preface nor in any prominent manner elsewhere does the author give credit to these source books. The book is by no means brief.

**Spontaneous Pneumothorax in the Apparently Healthy.** By Hans Kjærgaard. Paper. Pp. 252, with 29 illustrations. Copenhagen: Levin & Munksgaard, 1932.

This monograph is based on a study of the case records of fifty-one patients who had a total of sixty-one attacks of spontaneous pneumothorax resulting from rupture of a vesicle with a valve on the surface of the lung. It includes three cases of such unruptured vesicles found incidentally at necropsy and studied by the author. The case histories are given in detail. There is a comprehensive bibliography. The volume is an exhaustive and authoritative contribution to the subject.

***L'année thérapeutique: Médication et procédés nouveaux.*** Par le Dr. A. Ravina. Sixième année, 1931. Paper. Price, 16 francs. Pp. 182. Paris: Masson & Cie, 1932.

This little volume on new medicines and therapeutic procedures resumes the series interrupted in 1924 by the death of Dr. Cheinisse. It should be particularly welcome in this country as a help in the more general diffusion of knowledge concerning the newer therapeutic measures developed in Europe and especially among the French.

## Compensability of Sarcoma Following Trauma

*(Hertz v. Watab Pulp & Paper Co. (Minn.), 237 N. W. 610)*

Hertz fell in the course of his employment and was injured in the pelvic region. The fall did not immediately disable him, and he continued at work for some two months. All the while, however, he complained of the injury. Eventually he consulted a local practitioner, who told him that he had hernia. This diagnosis proved to be incorrect; it was found that he was suffering from a cancerous growth. Hertz applied for compensation under the workmen's compensation act, but his claim was rejected by the industrial commission, because it could find no causal relation between his fall and the admittedly malignant growth. On appeal, however, the Supreme Court of Minnesota remanded the proceeding to the commission, to consider such further evidence as might be offered.[1] The commission heard such evidence, but before it rendered a decision Hertz died. An autopsy showed that death was due to a "fibro sarcoma arising in the right pubic bone of a type which might be called primary sarcoma of the bone or osteogenic sarcoma." The industrial commission then found that the accidental injury that Hertz sustained was the cause of his death. From an award in favor of his widow, who had been substituted as the claimant, the employer appealed to the Supreme Court of Minnesota. That court affirmed the award of the industrial commission.

The opinion of the expert witnesses who testified, said the Supreme Court, differed as to whether the sarcoma from which Hertz died was or was not caused by his injury. Considering interested because he will find parallels with recommended remedies to many of his problems. Part II, devoted to hospitals, is a study in medical economics. The twenty-one hospitals in Kansas City, Missouri, and five in Kansas City, Kansas, are surveyed in detail as to bed capacity, bed occupancy, types of cases admitted, financial data and medical, nursing, laboratory, occupational therapy, dental and social services connected with the hospitals, together with studies of outpatient and clinic facilities. Special chapters are devoted to the tax-supported hospitals which come under the supervision of the director of health.

The dosage may also serve as a general guide in interstitial irradiation of this group of neoplasms. The author has been more partial to interstitial irradiation, as for example in the treatment of cancer of the lip, which is best treated by the application of radium on the surface by means of a mold.

**Mental Healers: Franz Anton Mesmer, Mary Baker Eddy, Sigmund Freud.** By Stefan Zweig. Translated by Eden and Cedar Paul. Cloth. Price, $3.50. Pp. 363. New York: Viking Press, 1932.

The mental healers included in this extraordinary volume are Franz Mesmer, Mary Baker Eddy and Sigmund Freud. The life of Mesmer reveals the beginning of magnetic healing and the opening of the temple in Paris. It credits *Puysegur* for his fundamental observations as to the effects of the mind on the body. The life of Mrs. Eddy is a burning analysis of her career which follows the Dakin and Milmine contributions for fact and which shows the manner in which the Christian science group have exploited financially the followers of the high priestess of the Christian science cult. In this section of his book, Stefan Zweig ventures numerous aphorisms as to the features of the American character that directed the extraordinary development of Mrs. Eddy's group.

For the work of Sigmund Freud, Zweig has great admiration. He does not, of course, concern himself with the manner in which the freudian doctrines have been so terribly exploited by the disciples and imitators of the great psychologic master. He presents the personality of Freud in a vital manner and reveals the background of freudian philosophy. The concluding sentence is enlightening: "And while the experts are still disconcerted because his teaching cannot be satisfactorily pigeonholed and docketed as 'medicine' or 'natural science' or 'philosophy' but partakes of the nature of all, while professors and pundits and privy councilors are still wrangling about its details and its ultimate value, the teaching itself has long since made good and been established as irrefutable—as true in that creative sense which Goethe has made immortal in the words: 'The fruitful, that alone is true.'"

**The Lancet Commission on Nursing Appointed in December, 1930, to Inquire Into the Reasons for the Shortage of Candidates, Trained and Untrained, for Nursing the Sick in General and Special Hospitals Throughout the Country, and to Offer Suggestions for Making the Service More Attractive to Women Suitable for This Necessary Work.** Final Report. Paper. Price, 2s. 6d. Pp. 256. London: The Lancet, Ltd., 1932.

This is the final report of the committee appointed by the *Lancet* in 1930 "to inquire into the reasons for the shortage of candidates, trained and untrained, for nursing the sick in general and special hospitals throughout the country, and to offer suggestions for making the service more attractive to women suitable for this necessary work." The report includes the reasons which the committee found for the shortage of candidates. It offers suggestions as to how the number of desirable candidates might be increased. The report is based on a large amount of pertinent information, is well edited, and contains a number of tables and charts. It is valuable for all who are interested in the proper supply of nurses, whether in Great Britain or elsewhere.

**The Foundations of Medical History.** By Sir D'Arcy Power, K.B.E., F.R.C.S., Consulting Surgeon to St. Bartholomew's Hospital. Johns Hopkins University, Institute of the History of Medicine. Cloth. Price, $3. Pp. 182, with 3 illustrations. Baltimore: Williams & Wilkins Company, 1931.

This volume contains the six lectures delivered by the author at the Institute of the History of Medicine in Johns Hopkins University. The writings of Sir D'Arcy in the field of medical history are numerous and invariably interesting. The present series includes an account of St. Bartholomew's Hospital; also some studies of biography, bibliography and iconography. The final essay is entitled Aristotle's Masterpiece.

**La maladie de Hodgkin: Lymphadénie aleucémique. Lymphosarcome. Pseudo-leucémie de Bonfils. Morbus Hodgkini de Wilks. Adénie de Trousseau. Granulome malin de Benda. Lymphogranulome malin. Lymphogranulomatose maligne, etc.** Par Paul Chevallier, professeur agrégé à la Faculté de médecine de Paris, et Jean Bernard, intern des Hôpitaux de Paris. Paper. Price, 75 francs. Pp. 293, with 69 illustrations. Paris: Masson & Cie, 1932.

This volume considers the typical forms of Hodgkin's disease and will be followed by a volume dealing with variations. The available knowledge about Hodgkin's disease is presented in an interesting, orderly form, nothing original being presented. The controversial matter of etiology is discussed. There is some repetition in subject matter, but the book is well outlined and indexed. The bibliography is especially valuable for its reference to the French and the Italian literature.

**Kolloidreaktionen der Rückenmarkflüssigkeit (Technik, Klinik und Theorie).** Von Dr. med. Willy Schmitt, Privatdozent und Oberarzt der Medizin, Universitäts-Poliklinik, Leipzig. Paper. Price, 12.50 marks. Pp. 181, with 72 illustrations. Dresden: Theodor Steinkopff, 1932.

The study of cerebrospinal fluid has become so extensive in recent years that entire monographs have been written on a single phase of the subject. In this monograph the author reviews the colloidal reactions on cerebrospinal fluid, including Lange, mastic, benzoin, paraffin, shellac and sublimate fuchsin. A detailed description of the technic and an interpretation of every test is given. The author has added nothing original, but he has covered the subject in all its phases. His familiarity with the minutest details shows that he has had a great deal of experience with the various tests. This is not a book for the general practitioner, but it will be found of distinct value to the laboratory worker.

**The Genius of Louis Pasteur.** By Piers Compton. Cloth. Price, $4.50. Pp. 361, with 8 illustrations. New York: Macmillan Company, 1932.

This biography of the great chemist who founded modern bacteriology is written simply and with understanding. It has not the brilliance of the book by Vallery-Radot nor is it as scientific as the contribution of Duclaux. It depends on these works for its facts, but neither in the preface nor in any prominent manner elsewhere does the author give credit to these source books. The book is by no means brief.

**Spontaneous Pneumothorax in the Apparently Healthy.** By Hans Kjærgaard. Paper. Pp. 252, with 29 illustrations. Copenhagen: Levin & Munksgaard, 1932.

This monograph is based on a study of the case records of fifty-one patients who had a total of sixty-one attacks of spontaneous pneumothorax resulting from rupture of a vesicle with a valve on the surface of the lung. It includes three cases of such unruptured vesicles found incidentally at necropsy and studied by the author. The case histories are given in detail. There is a comprehensive bibliography. The volume is an exhaustive and authoritative contribution to the subject.

**L'année thérapeutique: Médication et procédés nouveaux.** Par le Dr. A. Ravina. Sixième année, 1931. Paper. Price, 16 francs. Pp. 182. Paris: Masson & Cie, 1932.

This little volume on new medicines and therapeutic procedures resumes the series interrupted in 1924 by the death of Dr. Cheinisse. It should be particularly welcome in this country as a help in the more general diffusion of knowledge concerning the newer therapeutic measures developed in Europe and especially among the French.

## Compensability of Sarcoma Following Trauma

*(Hertz v. Watab Pulp & Paper Co. (Minn.), 237 N. W. 610)*

Hertz fell in the course of his employment and was injured in the pelvic region. The fall did not immediately disable him, and he continued at work for some two months. All the while, however, he complained of the injury. Eventually he consulted a local practitioner, who told him that he had hernia. This diagnosis proved to be incorrect; it was found that he was suffering from a cancerous growth. Hertz applied for compensation under the workmen's compensation act, but his claim was rejected by the industrial commission, because it could find no causal relation between his fall and the admittedly malignant growth. On appeal, however, the Supreme Court of Minnesota remanded the proceeding to the commission, to consider such further evidence as might be offered.[1] The commission heard such evidence, but before it rendered a decision Hertz died. An autopsy showed that death was due to a "fibro sarcoma arising in the right pubic bone of a type which might be called primary sarcoma of the bone or osteogenic sarcoma." The industrial commission then found that the accidental injury that Hertz sustained was the cause of his death. From an award in favor of his widow, who had been substituted as the claimant, the employer appealed to the Supreme Court of Minnesota. That court affirmed the award of the industrial commission.

The opinion of the expert witnesses who testified, said the Supreme Court, differed as to whether the sarcoma from which Hertz died was or was not caused by his injury. Considering their views in connection with other facts in evidence, however, the commission was justified in finding, as it did, that the injury to Hertz, though slight, either originated the sarcoma or exaggerated and excited it, so as to make the injury, within the view of the law, when administering the compensation act, the cause of the fatal growth.

---

[1] Hertz v. Watab Pulp & Paper Co. (Minn.), 230 N. W. 481, J. A. M. A. **96:** 1257 (April 11) 1931.

This court, said the court, has sustained awards of the industrial commission for compensation for sarcoma or cancer of traumatic origin in *Austin* v. *Red Wing Sewer Pipe Co.*, 163 Minn. 397, 204 N. W. 323; *Gaetz* v. *City of Melrose*, 155 Minn. 330, 193 N. W. 691; and *Halper* v. *The Golden Rule*, 180 Minn. 477, 231 N. W. 195. In *Storing* v. *Hotel Radisson Co.*, 177 Minn. 519, 225 N. W. 652, however, it sustained a finding of the commission against the occurrence of cancer as the result of an accident. In *Winchester Milling Corp.* v. *Sencindiver*, 148 Va. 388, 138 S. E. 479, a case similar to the one now before the court, the Supreme Court of Appeals of Virginia, in sustaining a finding that held that an injury had resulted in a sarcoma, said:

> Taking a common sense, practical view, as courts and commissions must take of the ordinary happenings of life, boiled down to its last analysis the medical theory is that there is a relationship between the receipt of injury and origin of sarcoma, and that the degree of injury plays no important part. With this in mind we find a perfectly healthy, strong man, who has never lost any time from work or complained of any illness, suffers an injury and from that time on is incapacitated, grows worse and worse, sarcoma develops at the point of injury, from which he dies. The lay mind, under such circumstances, can reach no other conclusion than that reached by the commission, viz., that the sarcoma was either caused by the injury or was aggravated by it.

A similar conclusion was reached in *Lewis* v. *Port of London Authority*, 7 B. W. C. C. 577, 111 L. T. Rep. 776.

In the present case, said the court, taking the lay testimony and the medical testimony into account, the commission was well justified in finding a causal connection between the injury and the sarcoma that resulted in the employee's death. The award in favor of the widow was ordered affirmed.

### Liability of Employer of Examining Physician

*(New York Central Railroad Co. v. Wiler (Ohio), 177 N. E. 205)*

Wiler, employed as a locomotive fireman by the New York Central Railroad Company, was directed to submit to an examination by the company's physician, so that the company might know his physical condition. He complied. Later he sued the company, alleging that its physician, while he was feeling with his fingers under and around Wiler's left groin, used unusual and unnecessary force and thereby caused a hernia. To Wiler's petition, the company filed a demurrer, which the trial court sustained. On appeal, however, the court of appeals, Lucas County, reversed that judgment and remanded the cause for further proceedings. Thereupon, the company appealed to the Supreme Court of Ohio.

On behalf of the company, it was contended that when a railroad company employs a physician to render any service for it and for its own purpose, which service that physician in his professional capacity might render to a patient for the patient's own purpose, the duty of the railroad company ends with the exercise of reasonable care in the selection of the physician. In support of this contention, the company relied on a decision by the Supreme Court of Ohio, in *Youngstown Park & Falls Street Ry. Co.* v. *Kessler*, 84 Ohio St. 74, 95 N. E. 509, which arose out of the treatment of Kessler by the company's physician for an injury received by Kessler in alighting from one of the company's cars. The purpose of the treatment in that case, however, said the Supreme Court, was to cure Kessler's injury. It was directly for the benefit of Kessler. If it was for the benefit of the company at all, it was only indirectly so, in mitigation of the damages it might be required to pay for causing the injury. That situation, the court held, created the relationship of physician and patient between Kessler and the company's physician. The fact that the company assumed the obligation to compensate the physician for the service he rendered did not alter that relation.

But in the present case, said the Supreme Court, the purpose of the examination was not to treat or cure Wiler, an employee of the appellant railroad company. It was to inform the company of his physical condition, so as to enable it intelligently to determine whether it could safely and profitably continue him as one of its employees. The examination was for the benefit of the company, and not for the benefit of the employee. Under such circumstances, the relationship between the company and its examining physician was that of master and servant, unqualified by the circumstance that the servant was as a matter of fact a physician. The action, therefore, was not an action for malpractice and subject to the statute governing the limitation of actions for malpractice. It was an action for bodily injury and the time within which action might be brought was determinable by the statute relating to actions for bodily injuries.

The judgment for the court of appeals remanding the cause to the trial court for further proceedings was affirmed.

## Society Proceedings

### COMING MEETINGS

American Association for the Study of Goiter, Hamilton, Ontario, June 14-16. Dr. J. R. Yung, 670 Cherry St., Terre Haute, Ind., Secretary.

American Association for the Study of the Feeble-Minded, Philadelphia, May 26-29. Dr. Groves B. Smith, Godfrey, Illinois, Secretary.

American Association of Genito-Urinary Surgeons, Niagara Falls, Ontario, Canada, May 26-28. Dr. Henry L. Sanford, 1621 Euclid Avenue, Cleveland, Secretary.

American Association of Medical Milk Commissions, Washington, D. C., May 20-21. Dr. Harris Moak, 360 Park Place, Brooklyn, N. Y., Sec'y.

American Bronchoscopic Society, Atlantic City, May 21. Dr. Richmond McKinney, 899 Madison Avenue, Memphis, Tennessee, Secretary.

American Gynecological Society, Quebec, May 30-June 1. Dr. Otto H. Schwarz, 630 South Kingshighway, St. Louis, Secretary.

American Laryngological Association, Atlantic City, May 19-21. Dr. George M. Coates, 1721 Pine Street, Philadelphia, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, May 23-25. Dr. Robert L. Loughran, 33 East 63d Street, New York, Secretary.

American Neurological Association, Atlantic City, June 6-8. Dr. Henry Alsop Riley, 117 East 72d Street, New York, Secretary.

American Ophthalmological Society, New London, Conn., June 27-29. Dr. Emory Hill, 501 East Franklin Street, Richmond, Va., Secretary.

American Orthopedic Association, Toronto, Canada, June 15-18. Dr. DeForest P. Willard, 1916 Spruce Street, Philadelphia, Secretary.

American Otological Society, Atlantic City, May 17-19. Dr. Thomas J. Harris, 104 East 40th Street, New York, Secretary.

American Pediatric Society, Rochester, Minnesota, May 26-28. Dr. Hugh McCulloch, 500 South Kingshighway, St. Louis, Secretary.

American Psychiatric Association, Philadelphia, May 30-June 3. Dr. Clarence O. Cheney, 722 West 168th Street, New York, Secretary.

American Surgical Association, New Haven, Conn., May 16-18. Dr. Vernon C. David, 59 East Madison Street, Chicago, Secretary.

American Therapeutic Society, Baltimore, May 16-17. Dr. Grafton Tyler Brown, 1801 I Street N.W., Washington, D. C., Secretary.

American Urological Association, Toronto, May 30-June 2. Dr. Gilbert J. Thomas, 1009 Nicollet Avenue, Minneapolis, Secretary.

Connecticut State Medical Society, New Haven, May 25-26. Dr. Charles W. Comfort, Jr., 27 Elm Street, New Haven, Secretary.

Georgia, Medical Association of, Savannah, May 17-20. Dr. Allen H. Bunce, 139 Forrest Avenue N.E., Atlanta, Secretary.

Illinois State Medical Society, Springfield, May 17-19. Dr. Harold M. Camp, 203 Lahl Building, Monmouth, Secretary.

Maine Medical Association, Rangeley, June 16-18. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.

Massachusetts Medical Society, Boston, June 8-10. Dr. Walter L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.

Minnesota State Medical Association, St. Paul, May 23-25. Dr. E. A. Meyerding, 11 West Summit Avenue, St. Paul, Secretary.

Missouri State Medical Association, Jefferson City, May 23-26. Dr. E. J. Goodwin, 634 North Grand Boulevard, St. Louis, Secretary.

National Tuberculosis Association, Colorado Springs, June 6-9. Dr. Charles J. Hatfield, 7th and Lombard Streets, Philadelphia, Secretary.

Nebraska State Medical Association, Lincoln, May 24-26. Dr. R. B. Adams, Center McKinley Building, Lincoln, Secretary.

New Hampshire Medical Society, Manchester, May 17-18. Dr. D. E. Sullivan, 7 North State Street, Concord, Secretary.

New Jersey, Medical Society of, Atlantic City, June 15-17. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.

New Mexico Medical Society, Santa Fe, May 19-21. Dr. L. B. Cohenour, 219 West Central Avenue, Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, May 23-25. Dr. Daniel S. Dougherty, 2 East 103d Street, New York, Secretary.

North Dakota State Medical Association, Grand Forks, June 1-2. Dr. Albert W. Skelsey, 18 Broadway, Fargo, Secretary.

Oklahoma State Medical Association, Tulsa, May 24-26. Dr. Claude A. Thompson, Manhattan Building, Muskogee, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

Rhode Island Medical Society, Providence, June 2. Dr. J. W. Leech, 369 Broad Street, Providence, Secretary.

South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Heart Journal, St. Louis

7: 279-414 (Feb.) 1932

Some Cardinal Circulatory Syndromes. A. M. Fishberg, New York.—p. 279.
Clinical Aspects of Arteriosclerosis. R. W. Scott, Cleveland.—p. 292.
Order of Ventricular Excitation in Human Bundle-Branch Block. F. N. Wilson, A. G. Macleod and P. S. Barker, Ann Arbor, Mich.—p. 305.
*Transverse Diameter of Heart. J. H. Bainton, New York.—p. 331.
*Diuretic Effect of Digitalis. E. L. Kellum, Rochester, Minn.—p. 342.
Gonococcus Endocarditis: Report of Case. H. B. Kirkland, New York.—p. 360.
*Diagnostic Value of Epinephrine in Angina Pectoris. L. N. Katz, W. W. Hamburger and M. Lev, Chicago.—p. 371.
Chart for Differential Diagnosis of Cardiac Enlargement by Means of Roentgen Ray. G. Levene and W. D. Reid, Boston.—p. 380.
*An Instrument to Determine Direction of Electrical Axis of Human Electrocardiogram: Based on Graphic Method of Carter, Richter and Green. M. Goodman, New York.—p. 383.
Coronary Thrombosis with Temporary Complete Heart Block: Case. Olga S. Hansen, Minneapolis.—p. 386.
*Left-Sided Displacement of Heart: Unusual Case. L. H. Sigler, Brooklyn.—p. 388.

**Transverse Diameter of Heart.**—Bainton considers the prediction table of Hodges and Eyster a fairly satisfactory guide in enabling an examiner to judge abnormality in the size of the male heart and to estimate the degree of enlargement. The adjusted standard for females in which the figures for males is reduced by 0.8 cm. is equally satisfactory. One half the internal diameter of the chest in the orthodiagram is a measurement which does not approximate the actual transverse diameter of the normal heart often enough to have much value as a standard guide.

**Diuretic Effect of Digitalis.**—Kellum studied the diuretic effect of digitalis on three healthy human subjects, and on twelve patients with congestive heart failure and considerable edema. One patient was observed and treated on two different occasions. None of the patients exhibited evidence of serious impairment of renal function. The study was made on one of the healthy human subjects three times, the diet and doses of digitalis being varied with each experiment. To insure standard experimental conditions, all the subjects were given a diet of weighed food, as constant as possible from day to day, of known low salt, water and protein content, the same as that employed by Keith, Smith and Whelan. The weighed food both of the healthy subjects and of those with myocardial failure is shown in a table. The total caloric values of the diet given to normal, healthy subjects were adequate, but the food given to patients with cardiac failure was low in total calories. This food was given to the patients with cardiac failure because they were at constant rest in bed, which reduced their caloric requirements, and because it was essential that all food should be eaten. The content of sodium chloride was low in all of the diets with two exceptions, and varied between 1 and 1.5 Gm. daily. The diets of patient 4 and healthy subject 1, experiment 2, contained approximately twice the amount of sodium chloride that was present in the others. Attention is also called to the low water content of all the diets except that of healthy subject 1, experiment 2, and that of patient 4, which contained approximately 300 cc. of water in excess of the others. The importance of the diet of weighed food, which was kept as constant as possible, is emphasized because there have been relatively few standardized experimental studies of digitalis in which such a diet has been employed. On the basis of his observations the author concludes that digitalis, when given to the healthy human subject in therapeutic doses and under the experimental conditions laid down in his study, seems to exert slight, if any, diuretic effect. The diuretic effect of digitalis in cases of cardiac failure with edema is uncertain; such effect may be marked, slight or absent. It is suggested that in the treatment of congestive heart failure and edema digitalis be employed for its beneficial cardiac effect, and that other substances be also employed for their superior and more certain diuretic action.

**Diagnostic Value of Epinephrine in Angina Pectoris.**—Katz and his associates reinvestigated the subject of the diagnostic value of epinephrine in angina pectoris on a group of six cases of known angina pectoris, on a group of six normal interns and in a case of "irritable heart" with precordial distress, and one of syphilitic aortitis with precordial distress. In every case the patient was put to rest in the decubitus position for half an hour before the observations were started. Serial electrocardiograms were made; the blood pressure, heart rate and in some cases the respiratory rate were followed and the subjective symptoms of the patient recorded. As a check, in suitable instances, the patient was subjected to a mild exercise to bring on his symptoms. The results are assembled in tabular form and characteristic curves are shown. In the normal cases, precordial distress was noted in two of the six subjects following epinephrine. In the angina cases, three of the six patients had no pain, although in one of them a typical pain attack was produced by exercise. Of the two abnormal cases (not anginal), an attack of pain over the precordium occurred in one but not in the other. It would seem from these results that the production of pain by epinephrine is not a reliable sign of angina pectoris. Furthermore, the pain when produced in two of three angina cases was long lasting and upset the patients greatly, and in one was not checked by glyceryl trinitrate. Even in the normal cases, one of the subjects had a severe symptomatic reaction presumably because of a susceptibility to epinephrine. On the basis of their observations, the authors conclude that epinephrine as a test for angina pectoris is unreliable in regard to both the symptoms produced and the electrocardiographic changes. This unreliability makes the test of little value, particularly in view of the severe reactions sometimes encountered.

**Instrument to Determine Direction of Electrical Axis of Electrocardiogram.**—By a slight modification of a graphic method for determining the direction and "manifest value" of the electrical axis of the human electrocardiogram described by Carter, Richter and Green and its application in the form of a handy instrument (of which an illustrated description is given), Goodman has found the method of considerable utility. The angle and manifest potential of an electrical axis can be estimated in a few seconds. The instrument is particularly valuable for teaching purposes, because it makes possible the visualization of the changes of the electrical axis in a cardiac cycle.

**Left-Sided Displacement of Heart.**—Sigler reports a case of sinistrocardia, most likely congenital, which from perusal of the literature he considers to be the only one of its kind on record. It was observed in a healthy man, aged 50, who had gone through life without any circulatory or respiratory embarrassment; the heart with its basal vessels was entirely displaced to the left of the spinal column and other mediastinal contents, such as the esophagus, trachea and bronchi, were likewise displaced. Although a history of injury was given, it seemed to be a mere coincidence, as there was no definite evidence of a pathologic condition the nature of which might be considered to be the cause of the displacement.

### Archives of Pathology, Chicago

13: 193-365 (Feb.) 1932

*Elliptical Human Erythrocytes: Report of Two Cases. M. C. Terry, E. W. Hollingsworth and V. Eugenio, Hines, Ill.—p. 193.
*Lesions of Nervous System Resulting from Deficiency of Vitamin B Complex. H. M. Zimmerman and Ethel Burack, New Haven, Conn.—p. 207.
*Renal Denervation: Effect of Snake Venom and Chilling on Renal Vascularization. G. Milles, E. F. Müller and W. F. Petersen, Chicago.—p. 233.
Experimental Infarction of Glomeruli in Dogs: II. Blood Pressure in Chronic Renal Insufficiency. C. R. Jensen and C. W. Apfelbach, Chicago.—p. 255.

**Elliptic Human Erythrocytes.**—Terry and his associates collected fifty-two instances of elliptic human erythrocytes, including two of their own. An analysis of the cases establishes the condition as an hereditary anomaly not incompatible with health and without any proved relation to disease, occurring in white persons, Negroes and mulattoes, and about equally divided between males and females. Both sexes may transmit it. A generation may be skipped. All four blood groups are represented. A necropsy is reported showing that oval cells were present in the smallest vessels of the cardiac muscle, spleen and suprarenals. An occasional oval erythrocyte was found in the marrow of the femur, and the marrow there, instead of having the usual yellow color and thick consistency, was reddish purple and semifluid or lymphoid. In other respects the necropsy disclosed nothing more than was anticipated from the patient's clinical condition, which was chiefly that of severe nephritis. Certain experiments are presented and discussed. Some of them were merely such as were necessary to establish the validity of the cases reported. Others yielded the following observations: 1. When the blood of one of the patients was subjected to the action of hypotonic solution of sodium chloride the oval cells resembled in their behavior normal erythrocytes rather than the poikilocytes of a patient with anemia. 2. Both round and oval cells were shown to exist together in the peripheral circulation, and the oval shape was shown to depend on structure and not on environment. 3. It was found possible to separate the two kinds of cells and to do certain experiments that showed that the oval cells were heavier than the round cells, and that they were more resistant than the round cells to the hemolytic action of hypotonic solution of sodium chloride. A speculation is offered as to the possible atavistic significance of the occurrence of elliptic erythrocytes in man.

**Lesions of Nervous System Resulting from Vitamin B Deficiency.**—Zimmerman and Burack found extensive demyelination in the sciatic, median, ulnar and vagus nerves and in the brachial plexuses of dogs deprived of the water-soluble B vitamins. This myelin destruction was most severe in the sciatic and least severe in the vagus nerves of all the animals subsisting on vitamin B-deficient ration. The extent of the anatomic alterations in the peripheral nerves varied in direct proportion to the severity and duration of the paralytic symptoms. Peripheral polyneuritis of the same type, but of a less degree, was present in the control animals, which were entirely deprived of food but supplied with an adequate amount of the B complex. Ganglion cell changes and disseminated foci of myelin destruction in the brain or spinal cord could not be held responsible for the clinical symptoms of this nutritional disorder. Dogs deprived wholly or in part of the thermostable $B_2$ factor showed large zones of degeneration and vascular proliferation in the vermis of the cerebellum and in the region of the substantia gelatinosa rolandi. A dog that had subsisted throughout the entire experimental period on a highly purified ration deficient only in the heat-stable factor ($B_2$) evidenced degeneration in the fasciculus gracilis of the spinal cord.

**Renal Denervation.**—By roentgenologic study of the vascular bed of the kidney in dogs, Milles and his associates demonstrated that renal denervation is followed by a long persisting dilatation of the cortical blood vessels. Chilling of the animal for a short time causes a definite vasoconstriction of the intact kidney as compared with the denervated organ; with prolonged and fatal chilling, this difference is no longer apparent. Daily chilling over long periods results in marked change of the vascular bed of the normal kidney, while the denervated kidney remains unaltered. A relation of the chill to the onset of acute nephritis, as well as of the effect of repeated spasm of the renal vessels (as with repeated chilling) to the pathogenesis of nephritic changes is made probable. A vascular poison, such as snake venom, causes greater injury to the denervated kidney, the normal kidney presumably protecting itself through vasoconstriction. The effect appears to be true for infectious diseases as well (distemper). No change in the vascular bed was observed with single doses of mercuric chloride or with repeated doses of uranium acetate.

**Antibody Response to Typhoid Vaccine.**—A comparison made by Tuft and his associates of the titers of agglutinins and complement-fixing antibodies after intradermal, subcutaneous, intramuscular, intravenous and oral methods of administration of mixed typhoid vaccine revealed a uniformly better and more persistent response after local injection, particularly after intradermal injection. Such results may be explainable on the basis of local stimulation of the formation of antibodies by the reticulo-endothelial cells, which are particularly abundant in the skin and subcutaneous tissues, or possibly by slow absorption of the antigen. The antibody response after any of the methods showed definite dependence on the antigenic potency or the age of the vaccine—the older the vaccine, the less the response. The general observations of others as to time of appearance of the agglutinins and complement-fixing antibodies, the variability in titer and the tendency to early disappearance were corroborated. A complete lack of uniformity in the titers of agglutination and complement fixation was observed in many serums; an adequate explanation for this is not apparent. The antibody response after oral administration of the vaccine was completely negative, in spite of the use of different strains of vaccine and different groups of persons. From a therapeutic standpoint, the intradermal injection of small doses of a freshly prepared and antigenically potent mixed typhoid vaccine receives experimental justification and has in the authors' hands proved satisfactory.

**Antibody Response to Inoculation with Typhoid Vaccine.**—According to Feemster, persons who have had typhoid or who have had inoculations with typhoid vaccine produce larger amounts of antibodies in response to subsequent inoculations with typhoid vaccine than those who have not had typhoid or been vaccinated against the disease. The routine injection of three doses of typhoid vaccine may not give as high a degree of immunity as has been believed. A second or third injection some weeks or months after the first would seem to be indicated. The Widal reaction is less reliable in the case of a person who has been vaccinated two or more times than in that of a person who has been vaccinated only once. The complement fixation reaction is no more reliable than the agglutination reaction in diagnosing infection with the typhoid bacillus. The difficulties and uncertainties encountered in carrying out and interpreting bactericidal tests render the procedure unsatisfactory for the routine diagnosis of typhoid. The severity of the reaction to the injection of typhoid vaccine is in no way related to the immunity that is formed in response to the injection.

Claude Bernard's Theory of Narcosis. V. E. Henderson and G. H. W. Lucas, Toronto, Canada.—p. 253.

**Pharmacology of Dehydromorphine.**—Travell made observations on frogs, rabbits, cats and dogs after oral, subcutaneous, intramuscular and intravenous administration of dehydromorphine acid tartrate in doses varying from 0.1 to 150 mg. per kilogram. Dehydromorphine, administered orally and subcutaneously in large doses, is inactive; injected intramuscularly and intravenously, it produces characteristic effects in the rabbit, cat and dog. The difference in the results obtained after various methods of administration explains some of the discrepancies in the literature regarding the activity of the drug. Dehydromorphine resembles morphine in many of the effects produced by its intravenous administration. It induces, in suitable dosage, prompt nausea, salivation and defecation (rabbit, cat and dog); marked fall in blood pressure after small initial doses, and often no change in blood pressure after continued larger doses (cat, dog); stimulation of respiration with subsequent depression, and death from respiratory paralysis (rabbit, cat and dog); convulsions (rabbits); hypnosis, somnolence and muscular depression (rabbit, dog). It differs from morphine in that it usually causes depression in the cat; it induces acceleration of the cardiac rate in the dog; it does not produce complete narcosis in any of the species studied. The probable seat of some of the actions of dehydromorphine is discussed, and it is suggested that the drug may act directly on the respiratory, defecation and vomiting centers in the medulla. It is demonstrated that dehydromorphine does not exert a curare-like action. A tentative hypothesis is advanced to explain its paradoxical effect on the blood pressure. The characteristic effects of the intravenous injection of dehydromorphine may be partially masked by the previous administration of morphine. The author concludes that her experiments afford no basis for the assertion that certain of the phenomena of chronic morphine poisoning are due to the formation of dehydromorphine from morphine in the body.

**Experimental Investigation on Treatment of Toxemia.**—Myers describes experiments in which he noted that digitalis when administered in a correct manner during the earliest stages of toxemia has a definite life-saving action. Early digitalization is necessary and must be slow and progressive. Animals so treated are able to tolerate several lethal doses of diphtheria toxin without succumbing. Digitalis and strophanthus prevent myocardial degeneration, which is a constant feature of the controls. Digitalized animals always respond by an immediate and profound leukocytosis to an injection of a lethal or a sublethal dose of diphtheria toxin. This increase in leukocytes is much greater than that obtained by injecting toxin into normal animals. Electrocardiographic records taken in these experiments showed no gross changes in cardiac rhythm or conduction.

**Operative Treatment of Joint Tuberculosis.**—Henderson believes that in joint tuberculosis conservative treatment has its greatest field of usefulness in the treatment of children; operative treatment has its greatest field in the treatment of adults. If the adult patient is in good general condition, and there are no draining sinuses, fusion should be produced when practical. The knee, spinal column, shoulder and hip are anatomically suited to a fusion operation. Each patient constitutes an individual study, and generalities that may be true in the main may not be applicable to the individual.

**Diagnosis of Gallbladder Disease.**—Hoffman presents an analysis of 155 patients who presented symptoms that warranted the removal of their gallbladders. The diagnosis was correct in slightly over 90 per cent. Stones were found in 77 per cent of cases. Pain was considered to be the most reliable symptom. Night pains occurred in 38 per cent of the pathologic cases, and, in the absence of a definite peptic ulcer history, is thought definitely to indicate the presence of gallbladder disease. Digestive symptoms, although suggestive of gallbladder disease, are not of great diagnostic value. The Graham-Cole test is of unquestionable value if the gallbladder fails to fill or if stones are visualized. The other observations are not considered to be very reliable. Eleven normal cases were studied and were found to present about the same symptoms as the pathologic cases. Four patients were completely relieved of their symptoms by the removal of their gallbladders.

**Coronary Arterial Disease.**—Nathanson states that there are two distinct clinical pictures associated with coronary disease: (1) the anginal syndrome, consisting of attacks of pain or acute dyspnea, and (2) the manifestations of congestive heart failure. Coronary disease with congestive heart failure is usually associated with hypertension and presents practically the same problems in diagnosis and treatment as congestive failure from other causes. The diagnosis of the anginal type is frequently of great difficulty, as the clinical picture may be atypical and variable. The diagnostic features of the anginal type are enumerated and discussed and an evaluation is made of the various diagnostic criteria. Significant physical sign are usually absent. The electrocardiogram is of great aid in diagnosis and shows some abnormality in about 70 per cent of the cases. There are two chief indications in treatment: (1) the treatment of the attack and (2) therapy directed toward the underlying pathologic changes and the prevention of attacks. The anginal pain is most favorably treated by the sublingual administration of hypodermic tablets of glyceryl trinitrate and usually requires morphine. Many cases respond satisfactorily to ephedrine. The therapy aiming at the prevention of attacks includes (1) the readjustment of the patient's activities and habits, (2) the use of coronary dilating drugs, and (3) surgical methods for interrupting the sensory impulses from the heart.

**Cancer of Breast.**—Bloodgood calls attention to the fact that thousands of women who have read the correct information in the daily press or who have learned it from their family physician, or have acquired the modern habit of annual examinations, have shown that the greatest risk a women runs today, if the lump in her breast proves to be cancer, is about 25 per cent, while the ignorant woman who delays largely because of her ignorance and not of fear has less than 10 per cent chance of a cure. Women need no instructions in what the warnings are. They will recognize them in time. But every woman needs special instruction how to act when warned. Recent figures show that when a woman seeks an examination the moment she observes anything unusual in one or both breasts, the chances are that 85 per cent of the warnings will be of such a character and the examination of such a decided observation that no operation or irradiation with roentgen rays or radium is necessary. In about 15 per cent of the cases of a lump of such distinct character it will be discovered by the finger of the physician or the transilluminating light that the lump must be removed, and the lump only. The lump is immediately subjected to microscopic study. In less than half of the cases, cancer or a condition suggesting malignancy will be discovered by the microscope, and the complete operation with removal of the breast must follow. In more than half of the cases, only the lump will have to be removed and the breast will be saved. Therefore the woman who seeks an examination at once runs the risk of cancer in less than 10 per cent of the cases and increases her chances of a cure from less than 10 to more than 70 per cent. Those who delay increase the incidence of malignancy and decrease the chances of a cure. Without doubt annual examinations of all women and semiannual pelvic examinations of mothers, during which the breast will be carefully surveyed, should increase the protection of women from death by cancer of the breast. As yet it is impossible to prevent the development of cancer in a woman's breast, but she can be taught and influenced to have the cancerous lump discovered and properly removed early, so that the chances of a permanent cure are best.

*Coagulation of Cervical Canal for Chronic Follicular Cervicitis. G. A. Remington, Chicago.—p. 16.

**Coagulation of Cervical Canal for Chronic Follicular Cervicitis.**—Remington states that by using the proper electrodes or applicators, active and indifferent, with the right amount of milliamperage, one can do an excellent surgical diathermy trachelorrhaphy and curettage. The applicators or electrodes, as he has designed them for his own use, are well adapted to the anatomic structure of the operative field and facilitate rapid effective treatment. With the patient placed on the table in the dorsal recumbent position, the feet elevated in stirrups, the buttocks well down to the edge of the table, a large bivalve vaginal speculum is inserted and adjusted to bring the cervix into good position and good vision. A disk applicator is inserted laterally and slid under the anterior lip, thus elevating the cervix. A ball-tipped electrode is then inserted within the cervical canal up to the internal os, both electrodes are connected to the terminals of the fixed point coagulating unit, and the current selector switch is placed at point 3 for fairly high milliamperage (2,000) to provide a long hot spark. The operator now steps on the foot switch and at the same time slowly withdraws the applicator with a light upward pressure so as completely to cover the roof of the canal; he allows a few seconds for the withdrawal, or just enough time to prevent any unnecessary cramping within the uterine cavity. He repeats this operation four times, making light pressure each time in four different areas, first on the roof or superior wall of the canal, second on the right lateral wall, third on the floor or inferior wall, and fourth on the left lateral wall, or vice versa, also placing the different disk electrode each time on the same side of the cervix on which pressure is made, so that he is always pressing toward the disk. After coagulation of the canal has been completed, the disk is withdrawn and the ring applicator is inserted by holding the shaft straight up over the mons veneris, moving the hand to the patient's left inguinal region, then raising and at the same time pressing down the ring (as in passing a sound in the penis), when it will slide in and around the cervix and fit snugly. The sharp electrode is placed in the long handle, the switch is turned to point 1, the foot switch is stepped on, and all tissue within the ring is coagulated by sinking the sharp point of the active electrode into the tissue to a depth of from one-eighth to one-fourth inch, taking first the posterior lip and later the anterior lip. For the first treatment it would be best to coagulate first the canal and part of the posterior lip or as much as the patient can stand without great discomfort. The degree of sensitiveness varies with patients. The author does not use any local anesthetic in these cases. In the greater number of large boggy lacerated cervices the external os will be a large irregular opening—almost round—instead of a horizontal slit. This is where the ball-tipped electrode is best adapted, as it gets into the folds or rugae and no tissue escapes treatment. It is impossible to do a complete coagulation in one treatment. The average case requires from three to six treatments to assure a good, clean, cervix.

**Tularemia.**—Data secured by Parker and his associates from a small area near Roy, Fergus County, Montana, during a period of mortality among local sage hens, have furnished added evidence that gallinaceous game birds are a potential source of human infection. Bacterium tularense was recovered from the tissues of dead and killed sage hens, and also from ticks of the species Haemaphysalis cinnabarina, with which the sage hens were infested. It was not evident whether Bacterium tularense was the cause of the epizootic or a secondary or incidental factor. However, a comparison of data secured from both inside and outside the affected area has shown that sage hens from within were much more heavily tick infested; they were the only ones shown to be carrying infected ticks. The evidence secured suggests that Haemaphysalis cinnabarina, a tick not previously incriminated, is a natural carrier of tularemia. Reports are included of infection with tularemia from quail, of two cases in which there was a possibility that infection was from quail, and of a possible case from dressing a sage hen.

**Epilepsy in Children.**—Peterman considers it desirable at present to retain the designation "epilepsy" to describe a certain disease complex of which the most characteristic symptom is periodically recurring convulsions. The convulsions are apparently immediately due, as are most convulsions, to a cerebral edema. The cause of epilepsy and of the periodic recurrence of the convulsive state is not known. The most important problem in the study of a patient with convulsions is a differential diagnosis, and the final diagnosis of epilepsy is made by exclusion. The practical treatment of the epileptic child (if he cannot be placed in a hospital for fasting and the ketogenic diet) may be summarized as follows: (1) a definite daily regimen which includes a long nap and a long sleep, meals at regular hours and a daily bowel movement; (2) a restricted carbohydrate and protein and a high fat diet; (3) fluid restriction to a minimum, at least to 600 or 800 cc. daily and less if convulsions continue, and (4) phenobarbital in large enough doses to control any seizures that may occur after or until the foregoing procedures are established.

**High Blood Pressure as an Early Sign of Toxemia of Pregnancy.**—It is shown by Browne that in the toxemia of later pregnancy a rise of blood pressure often precedes by a prolonged period the onset of albuminuria. During the interval between the rise in blood pressure and the appearance of albuminuria (varying in the reported cases from eleven to eighty-nine days), there are usually no symptoms or signs to suggest that the patient is in any way abnormal. There is some evidence that there may be, in the earlier stages of the pregnancy of patients who later develop toxemia, a temporary elevation of the blood pressure, which soon subsides and which may be an expression of increased neuromuscular irritability and of a greater tendency to vasoconstriction in such patients. The importance, for the timely diagnosis of toxemias of pregnancy, of routine estimations of blood pressure is emphasized. When these are made, treatment can be commenced at a very early period, with the obvious advantage of minimizing the risk of eclampsia and of chronic nephritis. The author believes that the term "albuminuria of pregnancy" is a bad one and is no doubt responsible for much of the permanent kidney damage that has in the past been a sequel of the toxemia of late pregnancy. Its use has pushed unduly into the foreground the albuminuria, which is really a late symptom, and has therefore tended to obscure the early hyperpiesis, and has thus been the cause of dangerous delay in diagnosis and treatment.

**Aortic Valvular Disease.**—Campbell and Shackle report that in a series of cases with disease of the aortic valves, the condition was due to rheumatism in 200, to syphilis in 55, to atheroma in 20, and to all other causes in 21 cases. Out of every six rheumatic cases, roughly, three of the patients had aortic incompetence and mitral stenosis, one had both with aortic stenosis as well, one had aortic stenosis and incompetence, and one had aortic incompetence alone. When there was no mitral disease there were two men for each woman; when there was mitral disease there were two men for every three women. They came under first observation at all ages, least commonly before 10 or after 50. There was so little difference between the ages of those with and those without aortic stenosis that its presence must depend on the severity and nature of the attack rather than on the length of time that had elapsed. Pure aortic stenosis was rarely found, and, as far as could be judged from the pulse pressure, the stenosis was relatively unimportant compared with the regurgitation, even when the signs were well marked. Among the syphilitic cases there were three men for each woman, nearly four fifths being between 40 and 60. Aortic stenosis was rarely or never present, and the average pulse pressure was much greater than in the rheumatic cases (110 instead of 70). Nearly all the atheromatous cases were men, between 50 and 80. Aortic stenosis was more important and more frequently present, the signs of regurgitation being often absent. Auricular fibrillation was present in 30 per cent of those who also had mitral stenosis, in 8 per cent of the rheumatic cases without mitral stenosis, and only rarely in the nonrheumatic group. Left ventricular preponderance was found in about half the electrocardiograms of those with pure aortic disease, normal limits being found in the remainder. The T waves were inverted, most often in lead I, in about one fourth of the rheumatic cases and in about half of the others. The prognosis was enormously better in the rheumatic group. The average duration of life after the development of aortic incompetence was probably twenty years, excluding those who died quickly from active rheumatic carditis. In the syphilitic group, on the other hand, it was not much more than two years after the development of symptoms, few patients living for eight years.

*Blackwater Fever. M. Ghiron.—p. 65.
*Achlorhydria in Pellagra. J. B. Guthrie.—p. 71.
Note on Filarial Worm Found in Sections of Nasal Tumor Excised from Child, with Especial Reference to Embryo. A. J. Noronha.—p. 74.

**Blackwater Fever.**—Ghiron studied the serum of four individuals who had suffered from a severe attack of blackwater fever. Serum was taken three or five days after the attack for ascertaining its modifications. It possessed a marked hemolytic faculty in vitro toward blood corpuscles that had absorbed quinine. Of the red cells taken from various animal or diseased subjects, those that belonged to patients with benign and malignant tertian malaria, either treated or not with quinine, had the faculty of being more easily dissolved. Therefore, to obtain an evident hemolytic curve it is necessary to combine three factors: red cells of malarial subjects and quinine and hemoglobinuric serum. The significance of the hemolytic curve is estimated from three points of view; namely, (1) if it is compared with the curve of red cells in quinine solution, (2) if it is compared to the hemolysis of quininized red cells and serum of normal and diseased subjects, and (3) from the importance that has to be ascribed to corpuscles of malarial patients. Therefore it must be concluded that in hemoglobinuric subjects a hemolysin is present which becomes evident when the red cells have absorbed quinine, but principally if they are taken from a malarial subject. In every hemoglobinuric patient a hemolysin is present, even if only attenuated, that may be demonstrated by the method mentioned. This hemolysin acts at different concentration and may disappear after a certain time. Its specific reaction cannot then be demonstrated in vitro. The characteristic points of the reaction are the following: 1. A serum of a hemoglobinuric subject, possessing active hemolysins, can disclose the presence of malaria in the individual who provides the blood corpuscles. 2. The malarial blood corpuscles that have absorbed quinine can reveal the hemolytic properties of the serum of an individual who has had an evident or a latent, clinically incomplete, attack of blackwater fever. 3. The negative reaction in serum of individuals who have suffered from blackwater fever allows the administration of quinine.

**Achlorhydria in Pellagra.**—On the basis of his study of 336 cases of pellagra, Guthrie concludes that the occurrence of hydrochloric acid in the gastric juice in a case of pellagra gives a somewhat better prognosis than if this does not exist, although achlorhydria is no absolute criterion of severity in pellagra. Achlorhydria may constitute a factor in the diagnosis of a doubtful case and may point toward a positive diagnosis. Histamine excitation of gastric secretion gives no striking increase or decrease in the percentage of incidence of achlorhydria noted. It facilitates the test somewhat in the sore-mouthed pellagrin, because it can be used with one insertion of the small tube and without any act of mastication or swallowing. The high incidence of achlorhydria in pellagra would seem to indicate the need of further study of this syndrome in order to shed light on the possibility of a relationship to pernicious anemia, even in the face of unlike blood pictures in the two diseases.

**Arterial Atony and Arteriosclerosis.**—Plesch sets out the thesis that arteriosclerosis is only one phenomenon in a constitutional systemic disease affecting more particularly unstriped muscle. The disease is by no means restricted to local areas; on the contrary, it attacks the whole vascular system simultaneously. The local changes, which are called atheroma, atherosclerosis, ossification of the arteries, and a number of other names, serve the purpose of strengthening the walls of excessively dilated blood vessels at points of greater strain. Arteriosclerosis is a disease that sets in at every age, that can be arrested, and that can be cured in the early stages and beneficially influenced in the later stages; it is not an ailment of old age which must of necessity be progressive and incurable. Even by purely local observation, it would be possible to distinguish between two forms of arteriosclerosis—namely, the arteriosclerosis of old age, due, in the strict sense of the words, to wear and tear, with its local atheromatous calcified areas as secondary mechanical hysteresis, and arteriosclerosis as a disease in itself, a constitutional systematic allergic primary condition of the smooth muscles, the sympathetic nerves, and the connective substance. These two types appear clinically quite independently of each other. Even though the pathologic anatomic alterations show no characteristic indications of the one or other type of the disease, and even if the histologic pictures are vague or very much alike, one is nevertheless compelled at the bedside to make a clear distinction between these two forms of the disease for a great number of reasons. The essential characteristic of arteriosclerosis cannot be the deposition of lime, for at every age, even in infancy, lime is found in the arterial walls in a surprisingly large number of cases. The primary cause of arteriosclerosis is the weakening both of the muscular and of the elastic elements of the walls of the blood vessels. If the weakened blood vessels are not able to offer sufficient resistance to the blood pressure, they become stretched and dilated. At points particularly exposed to dynamic pressure, alterations occur which in the end serve no other purpose than to raise the resistance of the walls. This process of alteration, which is completed by the deposition of lime plates, offers protection against rupture. Calcification and ossification are, therefore, not a disease but a healing process. The first local changes caused by excessive wear and tear in parts of the vascular walls are anatomically characterized by proliferation of the tunica intima at quite an early stage. The various layers and the specific elements of the arterial walls are involved to a varying degree in the disease process. Corresponding with the longitudinal and transverse tonicity of vascular walls, there must be longitudinal and transverse muscles that act independently of each other. The tone of the specific elastic elements must also be taken into account, because longitudinal extension narrows a blood vessel, and an excised blood vessel becomes shorter. The two muscular symptoms are functionally, and therefore also clinically, quite dissimilar in their behavior. The annular muscles counteract more particularly the internal pressure of the blood vessel, and the longitudinal muscles its longitudinal extension, while the elastic fibers of the artery regulate both strain and pressure.

**Diagnosis of Amyloid Disease.**—According to Wallace, the rationale of the diagnosis of amyloid disease by the intravenous injection of congo red depends on the essential fact that amyloid material absorbs congo red. An intravenous injection of an aqueous solution of this dye is made, and the percentage decrease of the dye content of the plasma (or serum) over a period of one hour is estimated colorimetrically. In the normal person an amount of from 10 to 30 per cent is found to have disappeared. In cases of amyloid disease there is a decided increase in the rapidity with which the dye leaves the blood, and a diminution at the end of one hour of anything between 30 and 100 per cent may be recorded.

**Lateral Pyocolpos.**—Papin describes a personal case in which the patient at the beginning experienced a periodic loss of black blood (hematocolpos) between the menstrual periods and later had purulent discharges (pyocolpos). The malformation present was what is designated in the literature as pseudodidelphic uterus (the uterine bodies separated and the cervices joined). The author believes that in lateral hematocolpos there is no communication between the blind uterovaginal canal and the normal uterovaginal canal; but when a small lateral opening communicates with the normal uterovaginal canal, open at the base, infection sets in and a pyocolpos results. In the consideration of diagnosis, uterine or uterovaginal malformations should be considered as a possibility. In the surgical treatment of pyocolpos, the intervention can be by the vaginal route or laparotomy and the blind vagina extirpated or simply the septum separating it from the normal vagina destroyed. However, laparotomy and dissection of the vaginal pocket is dangerous when the discharge is purulent. If the lesions are discovered after the hysterectomy (as in the author's case) it is preferable to cut the septum between the two vaginas. However, it is better, if the diagnosis is made early, to use the vaginal route for the intervention.

Chronic Rheumatism and Parathyroids. A. Laporte.—p. 37.
Parathyroid Hormone. H. Simonnet.—p. 40.

**Hyperparathyroidism and Osseous Syndromes.**—According to Sainton, there is no doubt at present as to the relationship which exists between hyperparathyroidism and certain osseous syndromes. The metaplastic diseases, according to Recklinghausen's classification, comprise fibrous osteitis and nonparasitic osseous cysts: Paget's disease, leontiasis ossea, the hyperostosic and metaplastic diseases forming tumors of the maxilla and giant cell sarcomas. Fibrocystic osteitis of Recklinghausen in most cases is a result of a hypertrophy of the parathyroids, usually adenomatous, which mobilize the bone calcium. The author does not believe the syndromes of Recklinghausen and Paget can be dissociated and opposed; the lesions and certain clinical aspects seem to point to analogous processes in the two, while leontiasis ossea is included in the group by reason of analogous roentgen signs, and osteosclerosis fragilis (Albers-Schönberg's disease) by reason of signs pointing to hyperparathyroidism. The author reasons that in osteopathies such as osteomalacia and rickets the decalcification forces the parathyroids to secrete and compensate for the loss in calcium. Therefore, hypertrophy is not always related to hyperactivity of the gland. The parathyroids can be adenomatous and not have any disturbance in secretion, and the adenomatous condition may be concomitant with both hyperparathyroidism and hypoparathyroidism. It is similarly true that patients with parathyroid osteopathies can have only temporary phases of hyperparathyroidism. After a discussion of the clinical, anatomopathologic and therapeutic aspects, he draws the following conclusions: 1. In the presence of a chronic osteopathy localized in one bone, roentgen and clinical examination should also include the rest of the skeleton, including the cranium, and the scapular and the pelvic regions. 2. If there is a chance of the presence of the syndrome of Recklinghausen or of Paget, the parathyroid region should be explored and examined either by palpation or by roentgenography for a probable tumor. 3. The calcium and phosphorus balance should be determined and compared with the activity and the progression of the osseous process. 4. Chronaxia of the muscles should be compared with the biochemical observations. 5. If the investigations lead one to suspect a parathyroid lesion, a methodical surgical exploration should be made and the parathyroid tumor should be removed. 6. After the intervention the patient should be carefully watched for the slightest signs of parathyroid insufficiency, so that hypoparathyroidism can be immediately counteracted by calcium medication associated with parathyroid hormone therapy.

**Surgical Anatomy of Parathyroids.**—Cunéo and Blondin find that in almost all their anatomic observations (95 per cent) the two parathyroids lie in the thyroid space, on the posterior face of the lateral lobe, in the neighborhood of the branching of the inferior thyroid artery; but in a few cases the glands lie under the capsule of the thyroid (4 per cent) or even inside the gland (1 per cent). In certain difficult cases in which exploration is fruitless, the authors advise resection of the terminal segment of the inferior thyroid artery together with the excision of a posterior band of the thyroid parenchyma. But in the majority of cases the authors recommend the following technic: The patient is placed in a position habitual for thyroid surgery. Anesthesia may be general, local or regional, but the authors prefer general ether anesthesia in order to avoid any infiltration that may occur. The best incision is the necklace incision, passing along the lower flexion fold of the neck. In bilateral extirpations, the incision takes the form of a curve slightly concave above and posteriorly; it unites the anterior borders of the two sternocleidomastoid muscles and passes beyond them 5 or 6 mm. The incision ought to be low in order to be hidden by a necklace in women patients. It is sometimes possible to make the incision in the lowest flexion fold, but the position of these cutaneous folds vary. Before incising the skin and the subadjacent cellular and cutaneous bed, one should arrest the hemorrhage from the arterioles and especially the veins, then incise the superficial cervical aponeurosis, and practice a débridement on the sternocleidomastoid muscle, parallel to the muscular fibers, in order the better to isolate the body of the muscle and thus facilitate its separation. Then the medial aponeurosis is incised. To isolate the parathyroids, one must cut the omohyoid and the sternocleidohyoid muscles and reach the sternothyroid muscle. In incising the latter at the level of its external border, one opens the thyroid capsule and penetrates into the parathyroid space. The thyroid capsule can easily be cut vertically at the external border of the sternothyroid muscle in order to put in place two retractors. When one has discovered the parathyroid, it is seized with well controlled dissection forceps and cut at its vascular pedicle. It is well to note that the intervention may be bilateral. The presence of an adenoma on one side does not preclude the presence of one on the other side. The authors did not observe any accidents of tetany when the intervention was limited to the principal gland.

**Infantile Tetany and Parathyroid Insufficiency.**—Lelong and Even discuss the literature and the anatomic, physiologic and therapeutic arguments and conclude that tetany in the child can be conceived as a form of parathyroid insufficiency. The resulting nutritional disturbance can be studied biochemically. Disturbance in calcium metabolism is almost always accompanied by hypocalcemia in young patients. Perhaps the fact that hypocalcemia may be present without tetany, and tetany without hypocalcemia, may be explained by nutritional modifications that are more complex than a simple hypocalcemia. The metabolism of fats, carbohydrates and especially proteins may play a part; the part played by guanidine and its derivative, creatine, has been suggested. The essential factor may be a disequilibrium between the various metabolisms rather than a disturbance in a single metabolism.

**Chronaxia in Hypoparathyroidism and Hyperparathyroidism.**—Bourguignon's studies show that, in general, hypoparathyroidism produces an increased chronaxia and a marked tendency to attacks of tetany through voluntary hyperpnea. On the other hand, hyperparathyroidism involves decreased chronaxia and great resistance (greater than normal) to attacks of tetany by voluntary hyperpnea. In both instances the variations in the chronaxia of the nerves and the muscles are parallel, in contrast to the condition in repercussions in which the chronaxia of the nerve remains normal while that of the muscle varies. The author believes that the latter difference may be due to the fact that the variations of the chronaxia in hypoparathyroidism and in hyperparathyroidism are humoral, while in repercussions the phenomenon is purely nervous and reflex, to which the muscle is more sensitive than the motor nerve. Furthermore, hypocalcemia increases the chronaxia and hypercalcemia diminishes it; some osseous lesions can cause changes in the chronaxia by reflex repercussion; and in numerous diseases with vasomotor disturbances the chronaxia varies with changes in the local circulation. The author believes that the study of the chronaxia of muscles should be given a place in the study of parathyroid disturbances.

**Rapid Form of Exophthalmic Goiter.**—Carnot and his co-workers report a case in which a woman, aged 29, in good health, suddenly experienced a painful thyroid congestion with considerable increase in the size of the gland, fever to 39 C. (102.2 F.) and extreme agitation. After a slight lull the fever, agitation and toxic signs increased. In one month the patient lost 20 Kg. (44 pounds) and registered a basal metabolism of 200 per cent. The aspect was impressive and the prognosis highly unfavorable: increased fever, exophthalmos, anguish, agitation, and tragic aspect. Death came on rapidly during coma (the disease lasted five weeks). The authors believe that clinically this case represents a remarkable example of a malignant, fulminating rapid form of exophthalmic goiter. The only histologic signs specific for the fulminating form of exophthalmic goiter consists in an extreme intensity and uniform diffusion of the primary or secondary glandular hyperactivity. The glandular hypertrophy is characterized by homogeneity of lesions, considerable epithelial hyperplasia with papilliferous proliferation and a pseudocancerous aspect, and an almost complete absence of colloid. One should hesitate in advising surgical interventions in such hyperacute cases. Medication by administration of iodine may help to place the patient in the best operative condition. Rapid ligation of the thyroid artery under local anesthesia is the best intervention.

**Periarticular Infiltration with Procaine Hydrochloride in Traumatic Arthritis.**—Leriche and Fontaine made this study subsequent to a previous observation of Leriche, who found that when injections of a local anesthetic were made at the level of ligaments and tendinous insertions in articular disturbances it was found possible to dissociate purely mechanical disorders from functional disorders that accompany them and sometimes exist practically alone. Furthermore, in certain instances, a therapeutic influence was noted. In instances in which the mechanical disturbances are reduced to a minimum and the impotence of the functional reflex dominates the scene, the functional disturbance either disappears or becomes less intense after local anesthesia. For sprains and traumatic arthritis the authors recommend repeated periarticular infiltrations, consisting of injections of from 10 to 25 cc. of a 1 per cent solution of procaine hydrochloride (without epinephrine); the injections can be made daily until recovery (sometimes four, five and six infiltrations are sufficient), and the patient experiences no inconvenience. Of course, the authors believe that the most favorable results obtained in their three cases of inveterate traumatic arthritis cannot always be guaranteed, but this therapeutic means should always be considered.

Acidosis and Diabetic Coma. V. de Antoni.—p. 704.

**Regular Extrasystolic Bigeminal Rhythm Associated with Cardiac Insufficiency.**—Capo reports, and illustrates with several electrocardiographic records, four observations of bigeminal rhythm occurring in heart patients with grave signs of cardiac insufficiency, following administration of small doses of digitalis or of ouabain. He analyzes the various pathogenic theories of this disturbance of cardiac rhythm and states that the appearance of bigeminal rhythm in the course of cardiac insufficiency may be considered a sign of grave prognosis. The patients studied died within two or three months after the development of the bigeminal rhythm.

**Pathogenesis of Morgagni-Adams-Stokes Disease.**—Calabresi describes a case of Morgagni-Adams-Stokes disease in which, in addition to the ordinary attacks, he observed other attacks similar in their nervous symptomatology but in which the stoppage of the circulation was absent while the oxygen and carbon dioxide content of the arterial and venous blood showed normal values. He discusses the cause of these attacks and concludes that the inadequate supply of arterialized blood brought to the medulla oblongata and the asphyxia of the myocardium may combine to cause also the classic attacks.

**Infantilism and Hypo-Evolutism in Disorders of Hepatosplenic Apparatus.**—Fittipaldi describes two cases of underdevelopment of the body, associated with lesions of the liver and of the spleen, which constitutes a contribution to the study of the hormone relations between the endocrine glands and the hepatosplenic apparatus. He concludes that such relations are not sufficient to explain the syndrome, and that not only the hypo-evolutism but also the hepatosplenic lesions may be regarded as expressions of an abnormal constitution.

Diagnosis of Pregnancy and Pupillary Reaction. T. Meneghini and C. Duc.—p. 113.

**Malignant Tumors Appearing After Radiation Therapy.**—Abruzzese suggests that it is well to watch carefully tumors not influenced, or only slightly influenced, by radium-roentgen treatment; to question the value of repeated application of such treatment, when the expected result is not secured, and to suspect irradiated tumors that show, following irradiation, an accelerated development, especially if there is a simultaneous appearance, persistence or accentuation of atypical blood losses. These, if they are isolated symptoms in women irradiated for any reason whatever, should be considered as recommending a meticulous diagnosis, with repeated biopsies and careful supervision of the patient, and if there is objective confirmation of the suspicion of a neoplasm not observed before the irradiation, it will be more prudent to exclude a new irradiation, and to resort rather to surgical treatment, which will more likely be complete, and hence definitively effective, the more carefully the operation is performed. This may prevent a diffusion beyond the limits of operability, which is, in such cases, rapid, as may be easily seen.

**Coconut Milk in Nutritional Disturbances of Infants.**—Gesteira and Bahia, on the basis of their experience with fifty infants with acute nutritional disturbances, conclude that coconut milk (obtained by pressing out the juice of the fruit after maceration), has a medicamentous and nutritive value and gives better results than almond milk as a transitional diet in acute nutritional disturbance in infants. The preparation of coconut milk is easier than that of almond milk, and at the same time its price is lower and its caloric value higher than that of almond milk. Because of the high caloric value of coconut milk (620 calories, whereas almond milk varies from 550 to 600 calories), coconut milk, instead of pudding, should be given to infants above 3 months of age, with nutritional disturbances.

**Ligneous Thyroiditis.**—Diez reports two cases of ligneous thyroiditis with a detailed anatomicopathologic study of the excised pathologic portion of the gland. He objects to the opinion that simple thyroiditis is only an early stage of fibrosis of the thyroid. He believes that the recognition of ligneous thyroiditis as a condition well differentiated from simple thyroiditis will increase if the predominant characteristic of the disease, namely, the high degree of retractility of the pathologic tissues, is borne in mind. The disease, because of its sclerosing and atrophic nature, may cause a complete compression of the patient's trachea or esophagus with death of the patient by asphyxia in the first case or by inanition in the second case. The etiologic agent, which up to the present time is unknown (although it is believed that the disease has an infectious origin), is probably the cause of the sclerosis of the tissues. Most authors believe that a cuneiform resection of the pathologic portion of the thyroid is sufficient to cure the patient. Payr, in 1927, reported two cases without recurrences after sixteen years of a cuneiform resection of the pathologic portion of the gland. However, Diez advises wide resection (at least a lobectomy) to prevent recurrences. Wide resection of the thyroidal tissues was made in both cases of the author. No recurrences have been observed a year and a half after the operation was performed.

*Involvement of Tonsils in Tuberculosis. J. Otto.—p. 187.
Pathologic Anatomic Investigations on Tuberculosis of Bone System. E. Randerath.—p. 201.

**Roentgenogram of Tuberculosis of Larynx.**—Thost points out that the former pathologico-anatomic investigations on the larynx have the disadvantage that the preparation of the specimens with strong acids causes considerable changes, especially in the calcium deposits. Since calcium has not only a physiologic but also a pathologic significance, the roentgenogram made of the living structure, which shows the distribution of the calcium, gives information about the pathologic processes not detectable by means of histologic examination. In tuberculosis the normal distribution of calcium and the ossification process is inhibited and replaced by a calcium infiltration. In older persons, in whom calcification has already taken place, the calcium decomposes; that is, in tuberculosis there is a decomposition of calcium. In syphilis the process is entirely different. Here osteophytes develop, and sharp, hard calcium bodies, star shaped or spherical, are noticeable on the laryngeal skeleton just as on other portions of the skeleton and corroborate the diagnosis of syphilis. Thus the roentgenogram has diagnostic and differential diagnostic value. If tuberculosis and syphilis concur, the tuberculosis, as the stronger component, supersedes the syphilitic processes. Occasionally, however, the calcium outlines characteristic for syphilis are still visible. The roentgenogram also shows all air spaces and accessory cavities of the upper respiratory tract, especially the small space of the sinus of Morgagni. If this space is absent in the roentgenogram, it is an indication that there is swelling and infiltration of the mucous membrane. Tuberculous processes frequently originate at this site and, although they cannot be detected with laryngoscopy, they can be recognized in the roentgenogram. Another advantage of laryngeal roentgenoscopy is that it reveals changes in the cervical vertebrae.

**Action of Hormone of Parathyroids in Tuberculous Hemoptysis.**—In experiments on fifteen rabbits, Bume and Liu found that following intravenous injection of the hormone of the parathyroids the coagulation time becomes reduced from 40 to 60 per cent. This reduction is manifest ten minutes after the injection, but after twenty-five minutes it begins to increase again, and in ninety minutes the initial value is reached again. Clinical observation of ten cases of tuberculous hemoptysis proved that, following administration of hormone of the parathyroids, the hemorrhage ceased in nine cases. In one case the parathyroidal hormone failed to check the hemorrhage, but in this instance all other hemostatics were likewise ineffective. The hemorrhage finally ceased following oral administration of a vitamin D preparation. In two other cases in which several other hemostatics had been employed without avail, the hemoptysis ceased after administration of the parathyroid hormone preparation. The results seem to be best if 1 cc. (20 units) of the hormone preparation is injected from two to three times daily.

**Involvement of Tonsils in Tuberculosis.**—Careful macroscopic and microscopic examination of the tonsils, especially the pharyngeal tonsils, of forty-five tuberculous cadavers, mostly of children, revealed to Otto that in about 74 per cent of the cases the tonsils were involved in the form of a secondary infection. A primary infection of the tonsils and of the intestine was observed only once. Studies on all the organs and the microscopic examination of the bones of the base of the skull make it appear probable that during childhood the secondary tuberculous infection of the tonsils usually develops by way of the blood stream. Studies in seven selected cases revealed no microscopic signs for the differentiation of a resorptive or of a hematogenic tonsillar tuberculosis. A differentiation is possible to some extent only in the beginning stages. A hematogenic origin is then indicated by the occurrence of numerous, similar tubercles in the subepithelial and in the perifollicular lymphatic tissue. An involvement of the follicles is only rarely observable. A *resorptive tuberculosis* can be assumed in cases of a pronounced involvement of the superficial subepithelial tissue layers. In somewhat advanced cases of resorptive as well as of hematogenic tuberculosis, the lymphatic tissue shows the most changes. The cases studied by the author gave no indications for the development of a tuberculous leptomeningitis by lymphogenic spreading from the tonsils. However, in spite of the frequent secondary involvement of the tonsils in tuberculosis during childhood, this complication has only in rare cases a certain significance for the course of the tuberculosis, for the tuberculous lesions of the tonsils usually heal by cicatrization, and extensive destructive processes are a rarity. The careful study of the hematogenic and resorptive tonsillar tuberculosis shows that it is difficult to determine the pathogenesis on the basis of the histologic observations.

**Nutritional Treatment of Diarrhea in Nurslings.**—Rosenbaum begins the treatment of diarrhea in nurslings with a fasting period of from six to twelve hours. Then he gives concentrated rice gruel (10 per cent), at first without the addition of carbohydrates, but on the second day he adds 3 per cent of carbohydrates in the form of sugar, and on the third day he adds 5 per cent. In order to increase the food value he later adds egg yolk to the rice gruel. Beginning with the fourth or fifth day, a milk mixture is gradually introduced into the diet by replacing first one and then two of the rice gruel feedings by milk. As the three kinds of milk that are most commonly used the author mentions protein milk, buttermilk and human milk. To counteract the dehydration he recommends oral administration of water. Only in cases in which the circulation fails is the parenteral administration of fluids advisable, in the form of subcutaneous injection of Ringer's solution. In order to prevent scurvy, fresh fruit juices should be given as early as possible. In severe cases, blood transfusion may prove helpful. Several transfusions of small quantities (20 cc.) are better than a single larger transfusion. As another important factor in the treatment of severe diarrhea the author mentions the permanent administration of oxygen. He describes a simple endonasal administration of oxygen, which he found helpful, especially in persistent intoxications.

**Diathermy Treatment in Diseases of Liver.**—Goldgruber employed heat by means of diathermy for the treatment of various disorders of the liver, such as in icterus catarrhalis, which may persist for weeks and even for months and may be a pathogenic factor in cirrhosis of the liver, also in cases of arsphenamine icterus that are refractory to other treatments, and in cases of chronic cholangeitis. His object in resorting to diathermy was to influence certain pathologic functions by active hyperemia and improvement of the circulation of the bile, also by resorption of inflammatory infiltrates and of metabolic waste products, further by the stimulation of secretion and of excretion, and by the regenerative action of heat on cells and tissues. By simultaneous application of the duodenal catheter, the author observed the therapeutic action of the diathermy treatment. He observed that whereas without the application of diathermy the bile was pale green, following the treatment it was darker and the flow was more profuse. The technic of the diathermy of the liver was simple. Plate electrodes 12 by 18 cm. were applied to the anterior and to the posterior region of the liver. The current strength was from 1 to 2.5 amperes, which was applied for two hours and was repeated daily or every other day. The total duration of the treatment varied individually. The method was employed in eighteen cases, three of which are reported in detail. Only in two cases did the diathermy treatment fail. Later the author tried diathermy treatment also in other hepatic disorders, such as cholecystitis, cholelithiasis and cholangeitis, and when pains were felt in the region of the liver following cholecystectomy. In conditions of this nature diathermy had been successfully employed by others, but the author was not able to duplicate these successes. On the contrary, he usually was obliged to discontinue the treatment on account of unbearable pains. He is unable to explain this paradoxical manifestation but thinks that the increasing biliary secretion may not have a proper discharge and thus lead to stasis and tension. Another problem that is yet to be investigated is whether the high frequency currents are active only by their resistance warmth or whether they also exert still unknown physical and chemical actions.

**43:** 1-93, 1932. Supplement

*Spontaneous Pneumothorax in the Apparently Healthy. H. Kjærgaard.—p. 17.

**Spontaneous Pneumothorax in the Apparently Healthy.**—Kjærgaard believes that "spontaneous pneumothorax in the apparently healthy" is a nosographic category of practical value. This term covers all cases of spontaneous pneumothorax that makes its appearance without any demonstrable cause in healthy persons, in whom no sign of tuberculosis may be demonstrated, either by auscultation and roentgen examination or by bacteriologic examination of the sputum, and in whom the disease takes an afebrile course, without pleural effusion. In this class are also included cases of this description with a slight rise of temperature in the first week of illness, and cases in which the roentgenograms show the presence of an insignificant pleural exudate, too small to be made out on auscultation. The disease is subject to great variation in clinical features and course, and there are all degrees of transitions between the various types. The disease is due to the rupture of a valve vesicle on the surface of the lung. There are two forms of valve vesicles. One form, the scar-tissue vesicles, develops especially in the apexes of the lungs, next to a scar that may originate from a small healed tuberculous process. These scar tissue vesicles are often multiple. The other form, the emphysematous valve vesicles, is produced alone through local emphysematous changes without scar tissue. These may be found as large solitary vesicles on the margins of the lungs. Probably the scar tissue vesicles constitute the more frequent form of valve vesicles. Systematic after-examinations of a large number of patients with long observation period have shown that in practice it may be taken for granted that this disease has nothing to do with active tuberculosis. So these patients should be spared the loss of time and the expense of a sanatorium treatment as well as the fear of pulmonary tuberculosis. The author suggests that spontaneous pneumothorax in the apparently healthy be called "pneumothorax simplex."

## OBSERVATIONS ON THE EFFECTS OF OXYGEN THERAPY

### I. CLINICAL OBSERVATIONS IN HEART DISEASE

W. W. HAMBURGER, M.D.
L. N. KATZ, M.D.; D. J. COHN, Ph.D.
AND
S. H. RUBINFELD, M.D.
CHICAGO

The past few years have witnessed the introduction into clinical medicine of an elaboration and intensification of the methods of administering oxygen-rich atmospheres for the amelioration of various diseases. Many workers and investigators in this field have published reports of their observations with results, for the most part, indicating the good effects of this method.

There is, however, some difference of opinion as to the degree of improvement to be expected from the use of oxygen, just which physiologic mechanisms it alters or modifies, and in which clinical conditions it is indicated. Certain claims for the efficacy of oxygen therapy may be considered unduly enthusiastic, even bordering on the extravagant—as is, unfortunately, so frequent an occurrence in the introduction of new or modified methods of therapy in clinical medicine. Conversely, certain reports may be accused of minimizing or disparaging its good effects.

In the present series of papers, an endeavor will be made by us (collaborating as a group in which are represented an internist, a physiologist, a biochemist, and their associates) to present the results of a combined bedside and laboratory study of a series of clinical cases in which oxygen therapy was employed, and thus to evaluate the rôle of an oxygen-rich environment as a therapeutic agent. In order to make this evaluation more accurate, an attempt was made to avoid as many other variants as possible. The patients were hospitalized for a short period before they were exposed to oxygen, and their management was stabilized. Observations made during this period were used as controls. The clinical management of the patient was kept as constant as possible during the course of the observations, excepting when the condition was obviously getting worse in spite of oxygen.

### PREVIOUS WORK

The interest in anoxemia, or "oxygen want," was created to a large extent by the studies of Haldane[1] and Barcroft[2] and their associates on the effects of high altitude, which are summarized in reviews written by these authors. Following this work the conception developed, and is now generally accepted, that anoxemia is an important factor in many diseases. Barcroft[2] drew attention to the presence of several types of anoxemia, which shared a common symptomatology. The three major types are:

1. Anoxic anoxemia, in which the hemoglobin of the arterial blood is for one reason or another not saturated with oxygen; that is, the hemoglobin in the arteries does not have the full amount of oxygen it is capable of holding. This type of anoxemia occurs when the inspired air is low in oxygen, or the aeration of the alveoli is impaired, or the diffusion of oxygen from the lungs to the blood is interfered with, or when part of the venous blood is shunted into the arterial system without coming in contact with air-containing alveoli.
2. Stagnant anoxemia, in which the minute-flow of blood is diminished.
3. Anemic anoxemia, in which the concentration of hemoglobin capable of carrying oxygen is reduced, whether by loss of red blood cells, or by mutation of the hemoglobin; viz., into methemoglobin, carbon monoxide hemoglobin and the like.

Heart failure, as is well recognized, is accompanied by the stagnant type of anoxemia and many of its symptoms and effects are produced in this way. Shock and acute coronary thrombosis can be considered as causing acute forms of stagnant anoxemia. In heart disease, especially in subacute bacterial endocarditis and in the hypertensive type associated with chronic glomerulonephritis, a severe anemic anoxemia may be present.

As might be expected when the circulation through the capillaries is slowed, a greater reduction in the oxygen content of venous blood than is normal, that is, an increased venous unsaturation, was found in cases of heart failure by Means and Newburgh,[3] Lundsgaard,[4] Harrop,[5] Scott,[6] and Barach and Woodwell,[7] among others. In cardiac decompensation there also occurs an anoxic anoxemia, which was first demonstrated by Harrop,[5] who showed that the hemoglobin of arterial blood in heart failure was not completely saturated with oxygen, and this has been confirmed by Barach and Woodwell,[7] Campbell, Hunt and Poulton,[8] Rabinowitch[9] and others. Not all cases of heart failure have

this arterial oxygen unsaturation even when they have increased venous oxygen unsaturation, as was shown by Scott,[6] Meakins, D'Autrebande and Fetter,[10] Fraser, Harris, Hilton and Linder,[11] and Kininmonth.[12]

The usual clinical test for anoxemia is cyanosis. Presumably this is a measure particularly of the anoxemia in the capillaries of the skin or mucous membranes. As Lundsgaard and Van Slyke[13] have shown, the skin color is dependent on the concentration of reduced hemoglobin and not on the oxygen saturation of the blood. In other words, regardless of the oxygen saturation, cyanosis will occur when the reduced hemoglobin equals 30 Gm. per hundred cubic centimeters of blood instead of the normal 5 Gm. per hundred cubic centimeters. Naturally, as Wiggers[14] reemphasized, the skin is an imperfect colorimeter which is affected by the vascularity of the region examined and by the thickness and pigmentation of the layers overlying the vessels. Lundsgaard and Van Slyke[13] pointed out that it is primarily the reduced hemoglobin in the capillaries which gives rise to the cyanosis. They also showed that the reduced hemoglobin in the capillaries is roughly the average of that in the arterial and venous blood. Consequently, slowing of the circulation, local or general, will lead to cyanosis even without the presence of an appreciable amount of reduced hemoglobin in the arterial blood. Cyanosis is therefore an index of stagnant as well as anoxic anoxemia.

Severe anoxemia, whether produced by cardiac disease or otherwise, alters the action of the heart directly as well as in many indirect ways. The subject has recently been summarized by Wiggers[15] and only the most important facts will be repeated here. Anoxemia leads to an acceleration of the heart rate, an elevation of systolic pressure; a slight drop in diastolic pressure, and an increase in pulse pressure may or may not occur (Greene and Gilbert[16] and Schneider[17]). The minute volume of flow is decreased in advanced anoxemia (Schneider and Truesdell[18]), although milder degrees have apparently the reverse effect (Strughold[19]). This early stimulating effect and later depressant action is apparently a direct action on the heart and is accompanied by dilatation (Strughold[19] and Jarisch and Wastl[20]). In addition, Resnick[21] has recently shown that anoxemia influences the conduction system of the heart, mild grades improving and severe grades depressing auricular, intraventricular and auriculoventricular conduction. Fatty degeneration of the heart, according to Barach,[22] may result from severe anoxemia. Other effects are produced by the increase in organic acids, the changes in the carbon dioxide of the blood, and as a result of the dyspnea set up by the anoxemia (Wiggers[15] and Peters and Van Slyke[23]).

Apparently the first attempt to administer oxygen in the treatment of a patient with cardiac insufficiency was made in 1908 by Beddard and Pembrey,[24] who found that breathing was improved by inhalation of oxygen. This finding was confirmed by Barach and Woodwell[7] and by Campbell, Hunt and Poulton.[8] Barach and Woodwell[7] found that inhalation of from 40 to 60 per cent oxygen mixtures for two to four hours increased the arterial and venous oxygen saturation, in the former to almost normal values. The cyanosis decreased, the breathing became slower, the pulse rate decreased, the carbon dioxide of arterial and venous blood increased in some cases, slurring of the Q-R-S lessened in two cases with bundle branch block, and the amplitude of the deflection decreased. Benedict and Higgins[25] had already shown that the slowing of the pulse was an effect of increased oxygen environment in normal persons.

Campbell, Hunt and Poulton[8] found that with the decrease in ventilation following inhalation of oxygen the alveolar carbon dioxide content rose. Boothby and Haines[26] pointed out that oxygen treatment is valuable only in relieving the patient of the added load and danger of anoxemia and must be continued until the anoxemia is relieved.

An extensive series of studies on the effect of oxygen therapy in heart disease was made by Barach and his associates.[27] In one group of cases presenting congestive heart failure and cyanosis, four were on the basis of arteriosclerosis and myocardial degeneration; two were active rheumatic cases with arterial anoxemia, and one was of long standing rheumatic involvement with a small amount of arterial anoxemia. This last case was not improved by oxygen. After a stay in a chamber with between 40 and 50 per cent oxygen for a time up to five weeks, the degenerative and the active rheumatic cases showed the following:

1. Clinical improvement manifested by relief of dyspnea, orthopnea and cough, slower pulse rate and disappearance of cyanosis.
2. Increased arterial oxygen saturation.
3. Marked increase in the arterial carbon dioxide content, a tendency for the $p_H$ to become more alkaline, a decrease in one case of lactic acid of the blood and, occasionally, a decrease in hemoglobin or red blood cells.
4. Decrease in pulmonary ventilation, usually with slowing of breathing.
5. Decrease in basal metabolic rate in a case in which it was elevated prior to administration of oxygen.
6. Decrease and subsequent disappearance of edema dependent on residence in 50 per cent oxygen, coming on from three to five days after commencement of oxygen therapy and associated with diuresis.
7. Increased vital capacity.

Med. **5:** 428 (Oct.) 1931.

The active rheumatic cases showed less striking changes than the degenerative, especially less diuretic action. Two cases of heart failure on the basis of pulmonary fibrosis and one on the basis of emphysema were also found to have similar improvement.

In four cases with coronary occlusion, Levy and Barach [27] found that oxygen therapy caused subjective improvement shown by relief of restlessness and respiratory embarrassment. Cyanosis was diminished or abolished, respirations slowed, Cheyne-Stokes breathing when present disappeared and the heart rate slowed. Barach [27] found in three cases of coronary arteriosclerosis in men in the fifth or sixth decade of life, accompanied by chronic cardiac pain present even while at rest in bed, that residence in oxygen lessened the frequency and severity of the anginal pain attacks. Baker [28] recently reported improvement of bundle branch block on administering an oxygen-rich atmosphere.

While oxygen therapy in recent years has made a fairly secure place for itself in the treatment of the pneumonias, in certain postoperative complications and some other diseases associated with cyanosis and anoxic anoxemia, its rôle in the treatment of diseases of the heart and circulation is still *sub judice* despite the reports quoted. It is in this type of disease that the major emphasis of our investigation has centered because we have felt the desirability of adding to our armamentarium any real advance in methods of treatment of this difficult and at times hopeless disease. Other types of cases were also included to serve, in a way, as controls.

### METHODS

With only one exception, a patient with acute coronary thrombosis, each of the patients who served as a basis of this study was observed for varying length of time in the ward or in private rooms before being placed in the oxygen chambers or tents. A number of routine control observations were made and the patients' management and, if possible, the progress of the disease stabilized. The routine observations included the usual clinical history, complete physical examination, blood pressure determination, chemical examination of the blood, electrocardiogram and the following special examinations: arterial blood oxygen content and saturation, carbon dioxide content of arterial serum and $p_H$ of arterial serum, the blood being obtained by puncture of the radial artery. Venous blood pressure both by direct and indirect method, vital capacity, pulmonary ventilation rate and breath holding time were also noted. In addition, the water intake and output were recorded.

The patients after this preliminary study were then placed in oxygen chambers [29] (in a few instances in oxygen tents) maintained at constant temperature (70 F.) and low relative humidity (30 per cent) with the proportion of oxygen kept between 45 and 50 per cent. The time of residence within the chamber varied from three to twenty-seven days. Several patients were returned to atmospheric air and subsequently returned to oxygen a second time, depending on the progress of the case and the particular problem under consideration. On the permanent return to the ward, observations were continued. The present report will deal only with the general clinical impressions and conclusions. The special examinations referred to are reported elsewhere.[30]

### OBSERVATIONS

Six patients with various types of cardiac disease were studied: three, aged 38, 42 and 44 years, respectively, with the diagnosis of rheumatic heart disease; three others, aged 60, 61 and 73 years, respectively, of the group generally considered as the degenerative type of heart disease, associated with generalized arteriosclerosis, particularly of the coronary vessels.

We shall first present brief reports of these six cases and then discuss them with a view of analyzing the effects of oxygen therapy.

### REPORT OF CASES

Case 1.—Mrs. C. B., aged 42, a secundipara, admitted for the second time to the hospital, Feb. 25, 1931, had complained since September, 1930 of "heart trouble," pain and swelling of the abdomen, edema of the ankles and orthopnea. The condition became worse following a sore throat six weeks previous to admission. The diagnosis was made of rheumatic heart disease, mitral stenosis and insufficiency with cardiac hypertrophy, auricular fibrillation and advanced congestive heart failure (class III).

After two days in the ward she was placed in the oxygen room for a period of eleven days. She was removed from the oxygen room, March 10, and placed in an oxygen tent two days later in an apparently moribund condition. At the end of three days in a state of delirium she tore off the tent and it was not replaced. She was discharged thirteen days later.

It was the clinical impression that there was no improvement during the first oxygen-rich period but marked improvement during the second period, followed by subsequent further improvement until compensation was again established. The patient at present is completely compensated. Diuresis started sometime after leaving the oxygen tent and was apparently related to digitalization and not to oxygen therapy.

Case 2.—Mrs. L. G., aged 38, a nullipara, admitted to the hospital, Sept. 21, 1930, had complained of "heart trouble," indigestion, palpitation, irregular pulse, orthopnea and edema of the legs since August, 1930. The diagnosis was made of rheumatic (and postdiphtheritic) heart disease, mitral stenosis and insufficiency with cardiac hypertrophy, auricular fibrillation, advanced congestive heart failure (class III) and recent infarction of the base of the left lung.

After fifty-five days in a private room she was placed in the oxygen room without other change in management. After a twenty-seven day stay in the oxygen room she returned to her private room, and she was discharged nineteen days later.

It was the clinical impression that there was improvement during oxygen therapy with progressive disappearance of the residual condition at the left base of the lung. The patient at present is completely compensated.

Case 3.—Mrs. S. B., aged 44, a quadripara, admitted to the hospital for the fourth time, Aug. 13, 1930, had complained for the past twelve years, and especially during the past seven years, that following colds she had dyspnea, precordial pain, orthopnea, edema of the legs and swelling of the abdomen. Her previous hospital admissions were for recurrent congestive heart failure. The diagnosis was made of rheumatic (and postscarlatinal) heart disease, mitral stenosis and insufficiency, aortic and tricuspid insufficiency, cardiac hypertrophy, auricular fibrillation, recurrent advanced congestive heart failure (class III), and old and recent infarction at the base of the right lung.

After a stay of six months and fourteen days in the ward, she was placed in the oxygen room for eleven days. On removal she was kept in the ward for six days and again placed in oxygen for seven days. Three days after removal from the tent she died.

It was the clinical impression that no improvement occurred during oxygen therapy. Death occurred in spite of all methods of therapy, including oxygen. No diuretic action of oxygen was noted.

J.; Katz, L. N.; Soskin, S., and Hamburger, W. W.: Observations on the Effects of Oxygen Therapy: III. Blood Chemical Changes, ibid., to be published.

Case 4.—Mrs. R. R., aged 60, an unipara, admitted to the hospital for the fourth time, July 15, 1930, complained of dyspnea, orthopnea, and severe agonizing precordial pain radiating to the left shoulder, lower jaw and left arm, two weeks before admission. Her previous admissions were also for heart failure. The diagnosis was made of arteriosclerotic heart disease, coronary sclerosis (with coronary occlusion), myocardial fibrosis with cardiac hypertrophy, angina pectoris, congestive heart failure (class III) and diabetes mellitus.

After four months in the ward the patient was placed in the oxygen room. On the sixth day of her stay in the oxygen room she died.

It was the clinical impression that the patient's course was progressively downhill. The patient was refractory to all forms of therapy, including oxygen. Oxygen had no diuretic effect.

Case 5.—H. B., a man, aged 73, admitted to the hospital, Feb. 23, 1931, complained of sudden acute dyspnea, with cyanosis, pallor and productive cough, three days prior to admission. The diagnosis was made of arteriosclerotic senile heart disease, coronary sclerosis with recent coronary occlusion, paroxysmal auricular fibrillation, emphysema, and congestive heart failure (class III).

The patient was placed immediately in the oxygen room and kept there sixteen days. He was discharged from the hospital twenty days later.

It was the clinical impression that during oxygen therapy there was marked improvement with relief of dyspnea, lessening of cyanosis and drop in pulse rate. The moisture at the lung bases continued, and weakness and cyanosis returned after withdrawal from oxygen. No diuretic effect of oxygen was noted.

Case 6.—Mrs. D. P., aged 65, a nullipara, admitted to the hospital, Jan. 2, 1931, suffered from vertigo, faintness and syncope, for ten days prior to admission. The diagnosis was made of arteriosclerotic heart disease, coronary sclerosis, myocardial fibrosis, partial auriculoventricular heart block and bundle branch block, Adams-Stokes syndrome, emphysema, no congestive heart failure (class II-b).

After three days in the ward she was placed in an oxygen tent for six days. After forty-four days more in the ward she was discharged.

It was the clinical impression that the patient's general condition improved during oxygen therapy, although no consistent change in the cardiac mechanism was observed. Oxygen had no diuretic effect.

## COMMENT

Patient 2, a woman, aged 38, one of the three rheumatic patients, had rheumatic and postdiphtheritic heart disease with mitral involvement and auricular fibrillation, and was resident in oxygen the longest time (twenty-seven days). She was the only one to secure what might be thought to be entirely satisfactory results clinically, with a complete return of compensation, and with the clearing up of an extensive residual pulmonary process at the base of the left lung, which was either an infarction or a pneumonic consolidation. The improvement in this lung complication seems particularly suggestive in view of the long duration of the process, persisting over a period of fifty-five days in ordinary room air in spite of all other methods of therapy used prior to oxygen therapy. The conclusion seems most probable that the disappearance of the lung process must be related in some fashion to the only variant in therapy; namely, oxygen.

The results in the other two rheumatic patients were not so promising. Patient 1, a woman, aged 42, with mitral stenosis and auricular fibrillation, showed no improvement during the first period of eleven days of oxygen-rich atmosphere. In fact, during this period—possibly because of the temporary postponement of digitalis therapy—her clinical course became progressively worse. However, after forty-eight hours' return to the ward, at which time digitalis was started—her condition being more critical—oxygen was again administered, this time in a tent, since she was too ill to be returned to the chamber. All observers at this time agreed that it was the clinical impression that oxygen was a life-saving measure and that without it the patient would have undoubtedly died. After three days of oxygen the patient objected vehemently to the enclosure and tore the tent off, and from this time on she slowly became compensated. Her recovery was obviously also related to the use of digitalis. This patient illustrates that oxygen therapy cannot be substituted for digitalis in a case presenting auricular fibrillation with rapid ventricular action.

Patient 3, a woman, aged 44, the final rheumatic patient, the mother of four children, had rheumatic and postscarlatinal heart disease, and aortic, mitral and tricuspid involvement with auricular fibrillation. She failed to show any improvement whatever, in spite of two trials with oxygen of eleven and seven days, respectively. Death occurred three days after the end of the second administration of oxygen. In scanning this patient's history, one sees that the recurrent periods of decompensation extended over a much longer time than the others—twelve years—and with particular severity and increasing frequency during the past six or seven years, as contrasted with a history of decompensation of only six months in case 1 and only six weeks in case 2. Likewise, the extent and degree of cardiac involvement was much greater in this fatal case than in the other two. One therefore concludes that, although in certain patients and under certain conditions oxygen appears to be a useful and active therapeutic agent, its usefulness and activity are subject to restrictions similar to those applicable to other therapeutic agents, such as digitalis, physiologic rest, diuretics and morphine; namely, if the integrity of the circulation, the reserve strength of heart muscle and the competence of the heart valves are too far spent, no therapeutic agent, oxygen included, is of avail in restoring the vital force to the circulation, and death ensues. In this connection it may also be of interest to observe that this patient, who died, was the oldest of our small series, and her damaged heart had already successfully withstood the strain of four successive pregnancies.

Turning now to the three patients with degenerative heart lesions, the first, patient 4, a woman, aged 60, with arteriosclerosis and diabetes, and with a previous history of recurrent (three) hospital admissions for heart muscle failure, entered the last time with a history of obvious acute coronary closure. After approximately four months of ward care, during which time the clinical course of her disease was progressively downward, she was placed in the oxygen chamber with no appreciable benefit, death ensuing six days later. One must conclude again that, in the face of widespread, chronic, progressive disease, oxygen, together with other therapeutic measures, has definite and sharp limitations. One point, however, should be emphasized in this case; namely, that oxygen therapy was not used until very late in the course of the disease, at least four months after the attack. It is conceivable that, had oxygen been instituted earlier, the result might have been quite different. The value and need of the early use of oxygen in the pneumonias has been quite convincingly demonstrated and in all likelihood applies to its use in cardiovascular disease as well.

The second patient with degenerative heart disease, patient 5, a man of 73, with an arteriosclerotic disease of the heart, with an acute coronary closure three days prior to admission, was placed in the oxygen chamber immediately on his entrance to the hospital. His subjective complaints of severe acute dyspnea, cough, restlessness and air hunger were immediately relieved, while objectively his cyanosis, pallor, pinched and anxious facies and mild tachycardia were measurably improved. After sixteen days of residence in the chamber he was removed to a private room, leaving the hospital three weeks later, apparently quite recovered except for the persistence of slight moisture at the bases of the lungs, some general weakness and pallor. His convalescence at home has been quite uneventful. While the patient might have recovered as promptly without oxygen, nevertheless one must be equally frank in definitely crediting oxygen with the prompt and effective relief of distressing subjective and objective conditions, thus possibly placing the heart and circulation in a most favorable situation for recovery. This alone, all would agree, is of great consequence and importance, both to the patient and to the physician, and of itself, in a given case, alone might justify the use of oxygen. Similar symptom controlling values are attributed to other therapeutic agents—morphine for controlling pain and dyspnea, digitalis for auricular fibrillation with rapid ventricular rates and diuretics for edema. While perhaps none of these are of themselves curative or crucial remedial agents, no physician, in his care of persons sick with heart disease, would care to get along without them.

The last arteriosclerotic patient, a woman, aged 65, with partial auriculoventricular block and an Adams-Stokes syndrome, was placed under oxygen to inquire particularly into its efficacy in improving intraventricular conduction as suggested by the work of Baker.[28] She remained in an oxygen tent for six days, during which time there was evident a general clinical improvement as evidenced by relief from the vertigo, the faintness and syncopal attacks from which she suffered, and a general impression of improvement in her restlessness, appetite and sleep. Careful and repeated electrocardiograms were taken before, during and after oxygen therapy, but without demonstrating consistent changes in the cardiac mechanism.

### SUMMARY

We may summarize our impressions and conclusions at the present time as to the value of oxygen therapy in diseases of the heart and circulation by the general statement that it has a definite, though possibly limited, rôle in the treatment of these conditions. We feel that this general statement, in the light of our experience, should be further amplified and qualified as follows: It appears that in those cases associated with pulmonary complications, such as congestion or consolidation, infarction, edema of the lungs and the like, oxygen may be of particular value. We feel further that oxygen in no sense should be considered a substitute for the older, well accepted method of therapy, namely, the proper use of digitalis, morphine and diuretics, but should be used in conjunction with them to serve as a useful and valuable adjunct. In critically ill or apparently moribund cardiac patients an oxygen-rich atmosphere may prolong life, add somewhat to the comfort of the patient, or stop the downward course of the disease and aid in the progressive return of compensation. Miracles cannot be expected, and in the presence of prolonged, advanced, progressive cardiac disease, as is true also of other available therapeutic measures, oxygen cannot achieve the impossible. Additional factors, adding to the burden of a probably poor prognosis, are the age of the patient, and, in a woman with a damaged heart, the history of repeated pregnancies. As in pneumonia, if oxygen is to be used it should be instituted early and promptly if the best results are to be obtained.

Symptom controlling values are attributed to other therapeutic measures, viz., morphine for controlling pain and dyspnea, diuretics for relief of edema, and digitalis for slowing the ventricular rate in auricular fibrillation with rapid ventricular rate. While none of these are of themselves crucial remedial agents, their use is justified even though they sometimes fail to act. In like manner, even if cure or improvement are not always to be expected, the relief of dyspnea, cyanosis, restlessness, tachycardia, the contribution to the sense of well being, and improvement in appetite, color and sleep may well repay the time, effort and expense of instituting oxygen treatment.

# PSYCHOTHERAPY AND GENERAL PRACTICE

LAUREN H. SMITH, M.D.
PHILADELPHIA

A recent number of the *Pennsylvania Medical Journal* contained a comment to the effect that the readers of papers before different medical groups should use care in ascertaining where their presentation might be most appropriately presented. "The physician who first and usually sees the patient is the general or family physician." For this reason, I wish to present briefly a few points about some of the patients who have been seen at the Institute of the Pennsylvania Hospital. These patients are those who have been greatly troubled with what is called general nervousness, depression, or other emotional difficulties. During the course of the day's work, both in the outpatient department and with the resident patients of the institute, one is astounded not only by the psychiatric difficulties and the evident need for good mental hygiene but also by the close association of these problems with those of general medicine found in the history or in the physical condition of the patient. Most of these patients are referred to the psychiatrist by the general practitioner, and the very troubles with which the psychiatrist is now dealing have undoubtedly been handled, knowingly or blindly, by the family physician, who, unfortunately, seems to be less and less in evidence. Since most of these patients go to see their family physician, it seems important that the experience gained by the neuropsychiatric specialists should be passed on directly and purposely to the physician who is usually consulted first, the general practitioner. One gets the impression that to handle some of these patients successfully the physician needs to be present in at least three identities; namely, doctor, confessor and lawyer. The present-day success of the shady sisters in therapeutics, as well as the popularity of unorganized quackery and charlatanism, is a warning of how necessary it is to manage skilfully the mental and emotional side of the patient, as well as his physical welfare. Many of the complaints and discomforts heard in office practice and in convalescence from serious illness or surgical procedure are out of proportion to the physical weakness present. Examination and treatment of the emotional life of such a patient

---

From the Consultation Clinic of the Institute of the Pennsylvania Hospital.

may result in great benefit to the physical illness as well as to the mental readjustment.

There are certain times during the progress of each individual from birth to death when stress and strain seem to make greater inroads. For brevity, I shall discuss briefly one case taken from each age period in which the stresses or strains may be particularly troublesome.

The first, childhood, is that period of childhood wherein the child becomes aware of his own identity as a person in relation to the human individuals about him. At this time, accentuated by the arrival of a baby brother, one child learned that the physical comforts and also the paternal and maternal love must be shared with the newcomer, or with other identities in the environment. A physical illness at this time placed the child in the center of the picture again and he emerged victor over the anxious parents, at the expense of the other associates in the environment. No matter how skilfully the medical regimen and treatment may be carried out, if the psychologic and emotional factors of illness are not carefully considered, difficulty may follow. This is particularly true of those patients who have epidemic encephalitis or any other of several generalized illnesses wherein there may be a high fever or a prolonged convalescence. In such an illness there is an organic nervous system undergoing unusual sensitiveness in its reactions and readjustment. Likewise, the mental or emotional impressions of the child are oversensitive, and their reactions are liable to be more extreme. No specific example is cited here, for not a day goes by that many cases are not seen. This is the type of case which is called "behavior problem" and the patients fill our child guidance clinics, juvenile courts, and children's institutions, although but a small percentage of them are criminal or deficient.

The second age period needing special consideration is that period of transition from childhood into early adolescence, ordinarily called puberty. At this time a great change is seen in boys and girls physically, but this change physically can never be as evident to the outsider as the change in feelings and interests which are entertained by the individual within. The points of view of the child become altered to those of an adolescent who is aware of new stirrings and a new consciousness. A great widening of mental aspirations and contact, as well as greater interest in physical accomplishment, takes place. If this transitional progress is made intelligently and without undue interference by environmental demands, it is usually not too difficult. If there is some physical disability, it may act detrimentally. One 12 year old boy was told by his parents, on advice of the family physician, that he had serious heart trouble and must never play outdoors with the other boys or he would die suddenly. From the age of 12 on he limited his activities more and more, until he was remaining indoors constantly, living only in day dreams and phantasy formation. This widened in extent until it began to undermine the normal working of his mind, and he was approaching a serious mental disease. A long continued reeducation of this boy's ideas and habits helped to correct the condition, but much irreversible damage was done to his personality. A second boy had trouble in adjusting to the awakening of sexual life within him and developed periods of depression because of nocturnal emissions and an impulse to masturbation. Therapy on the psychologic side desensitized him sufficiently to remove the frequency of his emissions and the intensity of his attention on his sexual stirrings.

A third age period, in some ways associated with the second, comes when the young adolescent finds the responsibilities of the economic world descending on him. The extreme ambitions of youth must be curbed because of economic necessity for family or self. Emotional conflicts often result, and this tendency to emotionalism may be displaced on some minor medical or surgical illness. A young woman of 20 had intense dysmenorrhea every menstrual period, and spells of vomiting. In addition there were frequent spells of diarrhea, intense headaches and sleeplessness. Detailed medical examination revealed undernourishment, considered to be secondary, and slight malposition of the uterus, which was easily corrected. The patient did not improve in any way, although she "was told there was nothing wrong with her by three professors in a medical school." Treatment from the psychiatric standpoint aided her in disposing of anxiety over economic limitations, worry over irregularities in conduct of other members of her family, as well as removing much concern over physical discomforts and sensations. The headaches, sleeplessness, vomiting, and diarrhea entirely disappeared following the psychotherapy, and the dysmenorrhea was greatly relieved, although no new or special physical treatments were given that had not been for some time ineffectual. The physical treatments were necessary and were the most important treatment points of the case, but they were ineffectual until the other factors were handled in conjunction.

The fourth age period might be called the turning point in life and comes as the menopause or involutional period. It is almost as active on the emotional side in men as it is in women, although one is not conscious, usually, of any physical manifestation of its presence. Perhaps it is correctly called "the dangerous age," but not in the usual sense ordinarily meant. Up to this time the individual sees himself progressing, looking forward. Now comes the time when certain phases of life are past and he must look both directions. Some take the view that they are on the downhill side of life and do not adjust skilfully, not realizing that this may be the most useful time of life for real accomplishment for themselves and others. Illness of any type at this time hits heavily if a good attitude of mind is not present. A patient having had a rather disappointing life as far as family and loved ones are concerned was working intensely hard, endeavoring to have her work make up for what she did not have in other ways. She became more and more exhausted, feeling more and more discouraged. Loss of weight developed, a neuritis began, and she finally had to stop work. Medical treatment succeeded in stopping her loss of weight and relieved the neuritis, but with this advance there developed constant regurgitation of food, crying spells, weakness and dizziness on exertion, and an internal sense of emotional tension which the patient said "made her feel as if she were going crazy." Months passed and no progress was made, and she was getting more and more depressed because of her unimproved condition and loss of time at work, as well as loss of money. Psychiatric treatment over a few weeks' time gave her a chance to pour out the worries, disappointments and unhappy thoughts she had had for years, and she began at last to make a slow but definite improvement to a recovery which placed her on a level of efficiency in work and happiness that she had not enjoyed before in the major part of her lifetime. As is true in so many patients at this particular age period, the glances she was taking at the "downhill side" of life had constituted a great item in contributing to the activation of her anxieties.

The fifth and last age period which may be outlined definitely may be the most indefinite of them all. This time may come when the physical infirmities of beginning old age seem to be greater than the enjoyable experiences of life at the same time. Some "do not grow old gracefully" and the physical difficulties of late life may prove to be a source of too great concern and anxiety. Therapy from the psychiatric standpoint is certainly as difficult as from the medical and the surgical standpoint but does make its contribution in giving relief. One man of 66, in good condition physically, was left very weak and depressed following a severe attack of influenza. He became worried over his weakened condition and feared a penniless old age. He developed extreme anxiety over a temporary digestive upset. A slight irregularity of the heart increased this anxiety until he was so worried that he was sleepless almost every night. One worry about his condition supplanted another, although none in themselves were of any significance. The vicious cycle served to develop one functional physical difficulty after another, and effective medical therapy accomplished its result only after intensive emotional psychotherapy was instituted. This patient is similar to many that we know of who have found readjustment successful after turning to Christian science. The emotional outlet they obtained under such a banner achieved its result. It is regrettable that it happens far too often under such circumstances, and as a result other patients strive for the same result and lose opportunity for health and happiness.

Our cases are by no means limited to these age periods, but those cited serve as examples for these special times. The variation of symptom combinations is no more limited than that seen in any medical clinic and office. One woman of 70 was unable to rid herself of terrific headaches due to cerebral arteriosclerosis until she had some emotional problems worked out, reducing the hypertension with resultant relief of the headache. Another woman of 50 got no result from repeated medical cures for her alcoholism, although she could quit easily for indefinite periods under a hospital regimen. With the help of her physician she worked out some feelings of inadequacy and inferiority she had had, and a recourse to alcohol did not seem necessary. Perhaps she had an organic makeup which made it easier for her to become alcoholic, but she became better acquainted with her mental makeup or attitudes, to the extent that she was able to adjust more satisfactorily without the alcohol as a refuge. A middle aged woman had been troubled with digestive upsets for years. They finally subsided for no known medical reason, and immediately she began to think people were talking about her, planning things against her, and she showed the signs of a definite paranoid mental picture. The connection between the two conditions is difficult to understand, but some relationship is certainly suggested.

Therapy, whether purely physical or purely mental, achieves results. Thyroid disturbances are nearly as common in the office of the psychiatrist as they are in that of the internist. It is striking how a basal metabolism can be reduced to normal limits by living a proper physical regimen and carrying out proper medical treatment. In a woman of 27, in whom an active thyroid disturbance had proved resistive to treatment by rest, compound solution of iodine and other medical measures, it was more striking to see what reduction in the basal metabolism took place with clinical improvement in classic symptoms when a great deal of emotional readjustment was made.

There is one type of case that seems to be fairly common in our present experience. I am thinking of several patients who have very similar complaints and symptoms, consisting of a feeling of great lassitude and weakness, lack of initiative, and a sense of physical and mental inferiority. In many of these cases there is a progressive loss of weight or a very marked undernourishment. Cartoonists seem to be aware of the frequency of these individuals in the community, and their essential characteristics, for we all are familiar with the lanky characters of the comics who are usually depressed or irritable, pepless or discouraged, and complaining of their health. This type of case has proved very resistive to our usual medical therapy, the patient not feeling any improvement that remained constant nor gaining or holding weight at any acceptable level.

Psychotherapeutic work with these people has proved to be of some assistance in getting them to a better level, both mentally and physically.

One side seems to help the other. In the office of the general practitioner, where we see so many people carrying the usual cares and troubles of life, it seems important to give consideration to that side of their personality. The individual is really an integrated whole, consisting of mental and physical aspects, each dependent on the other and influencing each other most profoundly. The effective prescription given for the best interests of the individual and patient should, in the ideal sense, contain therapeutic elements that will act as a specific for the mental side as well as for the physical.

111 North Forty-Ninth Street.

# TRAUMATIC INGUINAL HERNIA

JOHN J. MOORHEAD, M.D.
NEW YORK

Ever since the word "rupture" was used to denote hernia, there has been a widespread opinion that trauma is the responsible factor in the causation of the condition. The supposed relationship between injury and hernia is still accepted almost universally by the public; but most surgeons and many physicians long ago abandoned this view, their disbelief being based largely on observations made at operation. In medicolegal cases this whole topic is a matter of controversial importance, often vexing and perplexing to all concerned.

Before the situation is considered in detail, one should familiarize oneself briefly with (1) the basic anatomy, (2) the surgical operative observations, and (3) the pathologic reports.

The anatomy of the inguinal region may be briefly said to consist of an avenue called the inguinal canal, the uptown end of which is the internal ring, and the downtown end the external ring. Marching along this avenue may be seen certain male habitués, the spermatic cord accompanied by nerves and blood vessels, which disappear from sight after they pass through the downtown ring. Normally, both of these rings are mere slits or holes, but in some persons they are perfectly definite

---

From the Department of Traumatic Surgery, New York Post-Graduate Medical School, Columbia University, and Reconstruction Hospital Unit.

openings existing since birth and thus these individuals are congenitally prepared to have these openings plugged by pouting peritoneum, which in turn forms a very definite protrusion, which is called a sac. Hence, a hernia starts by being born and thus, by a process of gradual growth, sooner or later becomes apparent to the possessor or to the examiner. In other words, a congenital or preformed sac is always the essential precursor, and in every respect it denotes an attempt to buttress a weak area with peritoneum. If this sac appears at the upper end of the avenue, it is called an oblique or indirect hernia; but if it appears lower down it is called a straight or direct hernia. It has been recognized, of course, that a direct hernia is more like a ventral hernia and that it represents a grade of muscle weakness far more marked than in indirect hernia. To this extent it can be said that an indirect hernia is always congenital and that a direct hernia may be congenital or acquired. If acquired, it is on the basis of the preexisting weakness. It is known that normally this region is well protected by an interlacing group of muscles and that these are covered by a strong fascia. It is also known that these muscles are sometimes flabby, that often their interlacing is defective, that the lower end of the canal (the inguinal triangle) is often left without any muscle barriers whatever. It is known, too, that the fascia is often quite thin and that many times it has slits and gaps without any apparent cause. The essentials of this anatomic foundation can be summed up by the statement that in every case of inguinal hernia there is a basic defect, a congenital anomaly, just as predestined as a patent foramen ovale, or a clubfoot, or six toes. Nobody disputes these fundamentals for they have been known for centuries, and each generation of mankind has been heir to them; hence this discussion relates not at all to the production of a hernia by a given injury but, on the contrary, revolves about the problem of the aggravation of a hernia by injury.

The question, then, is: What is the relationship of trauma to an already existing hernia? One can take the ground that the hernia is "congenital," that it is "incipient," that it is "potential," that either ring is "dilated" or "lax," and that the injury in question is the causative factor because it suddenly produced intra-abdominal pressure enough to make the hernia apparent to the patient or to the physician. Intra-abdominal pressure, *vis a tergo,* so to speak, is obviously the only possible source of the aggravation and hence the element of greatest importance.

I[1] have ventured to compare the birth of a hernia with the birth of a child. The inguinal canal can be said to represent the cervical canal, and the internal ring is like the internal os and the external ring like the external os. In the one case at "full term" the presenting part is a fetus and in the other case a hernia. But in each case there was previous impregnation, continued growth, gradual dilatation and *vis a tergo.*

If, then, there is no formation of a hernia due to injury, except in the presence of actual laceration (virtually incisional hernia), what are the essentials of aggravation? This can be summated by saying that adequacy is the basic factor. If the violence is sufficient to produce enough intra-abdominal pressure to make the hernia evident, then this sudden onset should give appropriate immediate symptoms. In other words, anatomic and surgical common sense tells one that any quiescent sac suddenly dilated must inevitably register symptoms. It is known that any tug or enlargement or twist of a sac composed of peritoneum always becomes manifest; that has been seen during an operation on a developed hernia under local anesthesia with the patient half asleep from morphine or barbital. If it registers thus in a patient supposedly inert, how much more should it register in a patient unprepared? It is also known how a patient under local anesthesia reacts to manipulation of the omentum, the intestine or the region of the vas or testicle. And yet, despite all this, there are some who maintain that a hernia can be assigned to a forgotten or distant injury, and that the presence of the lump itself is all that is necessary to connect the accident and the alleged sequel. They reason that there must be some overt act to make the hernial mass appear, that this "something" is strain registering as intra-abdominal tension. It is the "last drop" that fills the pitcher and causes it to overflow, and hence this "last drop" is the responsible factor. That sort of reasoning could also adequately answer the question: "Who won the war?" or "What caused the depression?" It is the same kind of reasoning that asserts that the last pain gave birth to the child. If there is to be a relationship between the accused injury and the resultant hernia, there should be certain demonstrable proofs. What are some of these?

1. *Adequate Violence.*—This presupposes intra-abdominal pressure. Hence the nearer and more direct the violence, the greater the probability. A blow on the back should be by far a less likely factor than a blow on the abdominal wall. A strain of the abdomen, as by lifting or pushing or pulling, is an adequate cause of intra-abdominal pressure; so is repeated coughing, vomiting, straining at stool.

2. *Adequate Effects.*—These should be immediate for the reasons already given. Pain is the chief sign and it often is of the testicular variety, sufficient to cause imminent syncope, nausea and sometimes vomiting. Swelling ensues promptly and often this is accompanied by edema or ecchymosis. Tenderness on pressure is present, and the patient should protect himself accordingly. Disability due to these three cardinal signs should be immediate and in duration is proportionate to the extent of the increase in the size of the original hernia.

If pain, swelling, tenderness and disability occur as the immediate result, what will the physician find on examination? Obviously these subjective signs will be made objective by palpation, and if ecchymosis is present, further corroboration is afforded. A sac suddenly dilated is painful, and any manipulation of it will be resented, even after the lapse of twenty-four hours or more.

If, then, the foregoing prevails, there is no question as to the relationship, as to the adequacy of the cause or the effect. These are the criteria that make the determination as between the ascribed or claimed, and the ascribable or actual, cause. The patient may honestly enough believe that his manifestations are due to a given source; but the physician can prove by the history and the examination whether or not his surmise is correct. The patient may believe that his attack of colic was due to green apples; but the physician knows that it is due to gallstones. The patient may think that his pain in the back was due to lumbago from sitting in a draft; the physician knows that it is due to a kidney calculus. Not many people now believe that typhoid comes from sewer gas, but twenty years ago that was a rampant etiologic assertion. Ten years from now the traumatic origin of hernia will be just as obsolete. The older textbooks, in listing etiologic factors, would acclaim as chiefest of all "alcohol, syphilis, gout and trauma." The "and trauma" is still present, but it also is on the way out as a scapegoat.

---

[1] Moorhead, J. J.: Traumatic Surgery, Philadelphia, W. B. Saunders Company, 1917.

If, then, these essentials are necessary to link the hernia to the injury, what is to be said regarding the typical case, the vast majority of them, in which the patient finds the lump and then recalls some injury more or less remote? How can the pain be accounted for when the patient says: "I remember I had a sudden sharp twinge and I found a lump that night?"

My belief is that the sac is at times empty and at times filled. That is known, because of the many cases in which at one time a lump has been seen and felt and again no lump could be demonstrated, even after coaxing it to appear by all sorts of strains. If the sac is empty or filled, a puff of gas, a twirl of the omentum, a pinch of the neck of the sac, a contracture of overlying muscle, a wrench of the nerve—all or any of these can cause temporary pain. But pain itself, as previously stated, is not enough; there must be evidence of distention of the sac before the accusation is susceptible of surgical proof, and this registers by the signs already narrated.

Now, aside from these definite signs of aggravation, there are certain collateral clinical facts that make me say that aggravation of an already existing hernia is extremely rare as the outcome of any kind of trauma.

Statistics show that in the draft age (from 21 to 30 years) of approximately 2,754,000 men examined, 4 per cent of them had hernia well enough developed to be nonacceptable for full military service. If in that decade of 21 to 30, forty in each thousand had a hernia, how many in the decades beyond this must have hernia?

If this is so, a large proportion of male patients treated for other things must have hernia. Obviously, the greater the injury the greater the possibility of aggravation. Hence fracture of the pelvis, the hip, the spine should often be accompanied by signs of aggravation of a preexisting hernia. In my own experience with the injured I have never encountered hernia as a complication of trauma of any type, crushing abdominal and chest injuries included. This to me is one of the best proofs that isolated trauma is an exceptionally rare accelerating factor. It is pertinent to add that incarceration or strangulation occasioned by trauma is also exceeding rare. Most patients with strangulated hernia enter the hospital after working hours, usually in the early morning hours. My observation is that strangulated hernia is less common than formerly, and certainly I am now less often called out of bed to operate for this acute abdominal condition.

If thus far the improbability of an isolated or single trauma being responsible has been stressed and if hernia has failed to be found as an associate of severe adjacent injuries, is there still further proof? Yes, there are two more. One is the operating table proof, the biopsy. If the hernia is recent, a matter of hours or a few days, then certainly there should be demonstrable evidences such as edema, exudate, hematoma, recent adhesions and engorgement of vessels. I have never seen any such manifestation, and in a number of my cases the operation has followed the alleged onset by only a few hours. What are the manifestations? The classic situation is that the sac is hidden, that it has to be searched for and, when found, is detached only by dissection of adhesions that give every indication of long duration. Further, the size, texture or consistency of the sac is no index as to its age, for it is known that some old hernias have thin sacs and some new hernias have thick sacs. Likewise, the contents of the sac afford no clue as to the duration unless the group in which bands of adhesions bind the intestine or omentum to the sac is excepted. There is also that group in which the omentum is worn smooth and has assumed a conical or tapered contour from long residence in the sac. It is against every precept of abdominal surgery to expect recently traumatized intestine or omentum not to show appropriate evidences of irritation such as edema, exudate, hematoma, and fibrin flakes. All these are absent, even in recent cases, and the point is that at the operating table practically every case gives manifold evidences of ancient origin.

There is still another proof, namely, the pathologic observations. Some years ago Smith of Waterbury, Conn., called attention to the value of submitting the removed sac to the pathologist to determine whether or not there were signs of recent traumatic or inflammatory changes. Surely that should be a crucial proof, and, accordingly, there has been a pathologic report in practically all of the 232 cases used for the purpose of this review. The constant finding is chronic peritonitis, and the pathologists are of the opinion that it would require at least one year of irritation to convert the normal peritoneum of the sac into the state of chronic irritation usually encountered.

Here, then, are assembled a series of proofs to demonstrate that the assertion of the patient should not be accepted in view of the anatomic, surgical and pathologic proofs to the contrary. It is another example of the fallacy of accepting the assigned instead of the assignable cause. One is assertion; the other is demonstration. The vast majority of people believe that a blow on the breast is a precursor of that tumor which subsequently appeared. As medical men we know that this relationship is exceedingly rare and that in the vast majority of instances the blow was a mere coincidence.

Now, in the formation of hernia, in the development and inevitable progression of this condition, constant or repeated intra-abdominal strain is, of course, a factor in the march toward the external appearance of the "lump." But that is not the theme of my remarks, and I take no exception to the assertion that continued or repeated strain is an important element. As a matter of fact, I believe that every potential hernia grows, assuming that the individual subjects himself to repeated intra-abdominal strain, as represented by such every-day incidents as work, play, straining at stool, coughing, sneezing, vomiting and the like.

In passing, the question of recurrence after operation is of importance. Published statistics vary as between 2 per cent and 17 per cent, and obviously there is no such wide disparity if identical cases are subjected to review. The low rates of recurrence include children, women, and those in nonlaborious occupations; and in this group relapses naturally will not be numerous. If workmen alone are cited, then the recurrence rate will be higher, and, of course, recurrence will be greater in the direct than in the indirect varieties. A direct hernia, as stated, is virtually a ventral hernia and indicates that the possessor has weak abdominal supports to begin with and thus is not a good candidate for surgical repair. My own rate of recurrence among workmen is approximately 9 per cent, and to me the causes of operative failure are usually assignable to one of the following:

1. Incomplete closure of the external or internal ring.
2. Failure to recognize the coincident occurrence of indirect and direct hernia.
3. Postoperative complications such as coughing, vomiting or infection.
4. Excessive abdominal strain after leaving the hospital.

The majority recur within the first six months, but no final estimate of success or failure is worth much until five years has elapsed.

As to type of operation, I favor the Bassini method, with or without transplantation of the cord, and double suturing of the fascia. I have not used fascia lata except in that group in which the inguinal triangle has to be patched or protected because of inability to suture the muscle to the fascia, notably in the direct and recurrent varieties.

I use chromic catgut for the deeper layers and nonabsorbable material (cotton or silk) for the skin.

My former practice was to allow the patient to get out of bed on the twelfth day, but in the past two years I have modified this on the theory that early mobilization was just as good practice in hernia surgery as it is in fracture or joint surgery. Hence I now allow the patient out of bed on the eighth day, believing that in a selected group there will thus be less disuse atrophy and hence earlier return of normal support. By this plan I believe that the recurrence rate is lessening. I permit return to light work two weeks after leaving the hospital, and resumption of full work two weeks later. I caution all the men to bend forward when lifting or straining so that intra-abdominal pressure will thereby be lessened.

There is a group in which muscle and fascia are so firm that mere tying off of the sac is apparently all that is required. By contrast there is another group in which every resource appears inadequate for holding purposes. I am thereby reminded of my experience with other types of trauma, notable fractures. There is an inherent indeterminable healing factor in every individual, and until one tries, one does not know what this factor actually is. In hernia repair as in wound or fracture repair, there is the unknown "nonunion" element that cannot be appraised until success or failure announces itself by the lapse of time.

### STATISTICS

Statistics have been compiled by my assistant Dr. Walter D. Ludlum, Jr.

In two hundred and thirty-two consecutive adult male cases, 182 were unilateral and 50 were bilateral; there were 18 recurrent cases. Ninety-five per cent of the men were between the ages of 20 and 60 years; 52 per cent between 20 and 40. The average age was 37.5 years. The greatest proportion, 32 per cent, occurred in the fourth decade, from 30 to 40.

The duration in 12 per cent was less than one week; in 40 per cent, less than one month; in 75 per cent, less than one year.

The onset was sudden in 66 per cent, the result of a definite strain in 60 per cent, and of a gradual onset in 34 per cent.

It was direct in 25 per cent, indirect in 23 per cent, and direct and indirect in 36 per cent.

In the last five years, spinal anesthesia has been used in 86 per cent and gas ether in 14 per cent.

The Bassini operation was used in 47 per cent; the Bassini without a cord transplant in 40 per cent.

The recurrent group included eighteen cases, or 8 per cent. The time since prior operation averaged six and one-half years. The average duration of recurrence was twenty and one-half months; the average duration of symptoms, four and one-half months.

Complications included one death (0.4 per cent) from peritonitis due to bladder injury; pneumonia or pulmonary complications, 6.8 per cent, and suppuration, 3.8 per cent.

In 63 per cent of the series reported, fibrous thickening of the sac occurred in 52 per cent, inflammatory changes took place in 16 per cent, fibrous and inflammatory changes took place in 10 per cent, and no changes were found in 22 per cent.

The same figures pertain to the group with sudden or with gradual onset.

### CONCLUSIONS

1. The preformed sac is the essential factor, and this is the congenital element of greatest importance.
2. Every inguinal hernia in the adult male has an inherent and inevitable tendency to increase and, sooner or later, may become manifest to the possessor or to the examining physician.
3. Aggravation of the hernia by some form of intra-abdominal pressure can be accomplished if the violence is adequate and the symptoms are appropriate. These symptoms are immediate in onset and consist essentially of pain, nausea, swelling and local tenderness.
4. Aggravation in reality is less common than is suspected (*a*) because evidences of it are almost never seen in the presence of even severe contiguous injury, (*b*) because at operation there are no local signs of recent trauma, and (*c*) because the pathologic examination also fails to show evidences of recent trauma.
5. A postoperative recurrence rate of approximately 10 per cent occurs among workmen.
6. Prolonging the period of postoperative convalescence may hinder rather than benefit the patient by inducing muscular atrophy of disuse.
7. The relation of hernia to a given trauma can be proved only by (*a*) the history of intra-abdominal pressure followed by immediate symptoms, (*b*) the operative observations, and (*c*) the pathologic report.
8. An isolated or single injury is never the source of origin of inguinal hernia, and aggravation or acceleration by trauma is exceedingly rare.
9. Traumatic inguinal hernia is a myth that should be consigned to the museum of historical relics of a bygone era.

**The Sun Today and Yesterday.**—The radiation from the sun is at the expense of its mass. No less than 360,000 million tons of matter is destroyed every day in order to maintain the present radiation of the sun. Poor old Sol weighs 360,000 million tons less today than he weighed at this time yesterday! By our human standards this prodigal expenditure cannot keep up for very long, but our human standards are not astronomical standards. Computation shows that the sun is not very much different today than it was when the planets were born. The weight of the sun is so inconceivably great that in order to show any material change in weight or radiation we must go back, not 2,000 million years, but five million million years. The sun weighed about twice as much then as it does now, and was correspondingly brighter and hotter.—Maxim, H. P.: What Is It All About? *Scientific American,* April, 1932, p. 199.

# MEDIASTINAL DERMOID CYST

## REPORT OF A CASE IN WHICH THERE WAS PANCREATIC TISSUE, SIMULATING INTRATHORACIC GOITER

E. H. CROSBY, M.D.
AND
ALLEN GRAHAM, M.D.
CLEVELAND

The mere addition of another case of mediastinal dermoid cyst to those already recorded in the literature would hardly seem to be justified. Our purpose in reporting the following case is to emphasize the possibility of the confusion of mediastinal dermoid cyst with intrathoracic goiter, and more particularly to record the occurrence, unique in this case so far as we have been able to determine, of pancreatic glandular and islet tissue in the cyst wall.

### REPORT OF CASE

A woman, aged 35, entering the Cleveland Clinic Hospital, Oct. 22, 1929, complained of marked dyspnea on exertion and of a tumor in the suprasternal notch.

The tumor, which was first noticed two years previously as a slight, tender swelling, had persisted for two days and then disappeared. At that time the roentgenographic examination of the teeth gave negative results; the tonsils were removed on account of chronic infection. Since its first appearance the swelling had recurred intermittently in the suprasternal notch and above the sternal end of the right clavicle, remaining for a few days and then subsiding.

At the time of admission the patient complained of shortness of breath, difficulty in swallowing, a slight nonproductive cough and hoarseness. There had been no increased nervousness, no loss of appetite or weight and no gastro-intestinal or genito-urinary symptoms. The patient was well developed and was not acutely ill. The past and the family history revealed nothing of importance.

Physical examination showed a tumor mass about the size of a hen's egg protruding into the suprasternal notch. During the act of swallowing, this mass followed the movement of the trachea. There was no thrill, bruit or pulsation. An area of upper mediastinal dulness extended 4 cm. to the right and 5 cm. to the left of the midsternal line. Examination of the heart, lungs, abdomen and extremities revealed no significant abnormality.

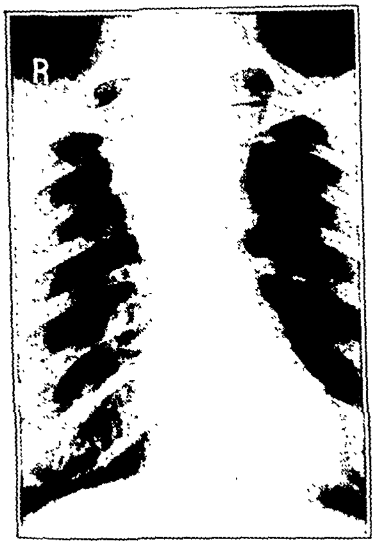

Fig. 1.—Appearance of the chest, showing the mediastinal tumor.

A roentgenogram of the chest (fig. 1) revealed a large tumor mass in the upper mediastinum, which was interpreted as a substernal goiter extending down to the third interspace anteriorly. The red blood cells numbered 4,000,000; white blood cells, 9,200; hemoglobin, 75 per cent. The basal metabolic rate was minus 7 per cent. The blood sugar before operation was 108 mg. per hundred cubic centimeters, one and one-half hours after eating. The blood sugar after operation was 75 mg. per hundred cubic centimeters fasting. The Wassermann and Kahn reactions were negative. The urine was essentially normal on four examinations.

A clinical diagnosis of substernal goiter was made, and the patient was operated on by Dr. G. W. Crile. Under nitrous oxide-oxygen anesthesia and procaine infiltration a low collar incision was made as for thyroidectomy The pretracheal fascia and muscles were separated in the median line, an apparently normal thyroid gland being exposed. Below the isthmus of the thyroid and bulging into the suprasternal notch could be seen a tumor mass which extended into the mediastinum and apparently had no connection with the thyroid. Early in the process of freeing the tumor, a cyst was ruptured and approximately 150 to 200 cc. of thin, brownish fluid escaped. The character of the fluid suggested that the lesion was a dermoid cyst. The partially collapsed cyst wall was removed with considerable difficulty, on account of its intimate relationship to surrounding mediastinal structures. After the removal of the cyst, a large cavity, measuring approximately 12.5 cm. vertically and 7.5 cm. transversely, remained, bounded below by the arch of the aorta, anteriorly by the sternum, on the right by the innominate artery and vena cava, and on the left by the carotid and subclavian vessels. Posteriorly, the cyst wall was in relation to the trachea and bronchi. After the cyst had been removed, the cavity was rinsed with saline solution and lightly packed with petrolatum acriflavine gauze. The operative wound was left open in order to allow free drainage. The patient was in excellent condition at the completion of the operation.

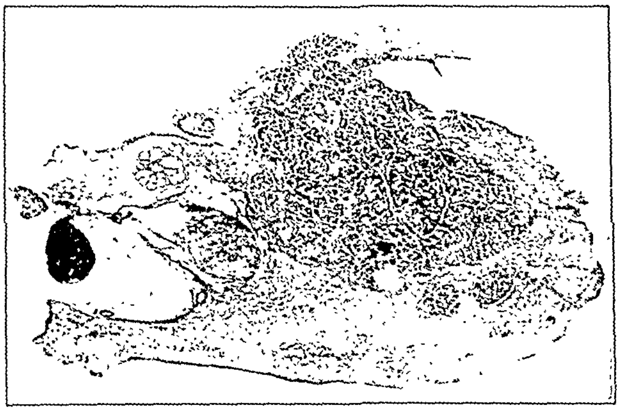

Fig. 2.—Section of the cyst wall showing the mass of lobulated pancreatic tissue; slightly reduced from a photomicrograph with a magnification of 6 diameters.

The postoperative reaction was slight, and on the second postoperative day the cervical wound was closed around a small rubber catheter. The wound healed satisfactorily and the patient was discharged on the eighteenth day after the operation. At the time of discharge, abductor paralysis of the right vocal cord was present.

One year following the operation, a letter from the patient stated that she was in excellent health, that there was no evidence of recurrence, and that she was not hoarse.

Macroscopically, the tissue received in the laboratory consisted of a ruptured, collapsed cyst wall, weighing 45 Gm. and measuring 12 by 6 by 1.5 cm. It was irregularly pear shaped. The cyst wall was fibrous and varied from 3 to 15 mm. in thickness. The inner surface was rough and somewhat trabeculated and had numerous small masses of yellowish-brown granular material adherent to the lining. There were numerous small outpouchings in the wall and several small, round, pouched-out areas, suggestive of ulceration, but without any plastic exudate. In several areas, irregular masses of yellowish tissue were present in the wall, limited chiefly to the inner half. No hairs and no cartilage or bone could be recognized on gross examination. The outer surface of the cyst consisted of irregular, shaggy, fibrofatty tissue on the posterior aspect and a comparatively smooth, shiny, membranous layer on the anterior aspect.

Microscopically, the inner lining of the cyst consisted largely of fibrous tissue devoid of epithelium, but in some areas, particularly the thicker portions of the cyst wall, were fragments

---

From the Cleveland Clinic.

of stratified squamous epithelium, without keratohyaline material or hair shafts. Beneath this were a few lobules of sebaceous glands. No coil glands were recognized. In other areas, the inner lining consisted of simple, columnar mucus-secreting epithelium, and beneath this was a large mass of nonencapsulated, lobulated, glandular tissue and ducts lined with cuboidal epithelium (fig. 2). This tissue had the morphologic characteristics of pancreas (fig. 3). Scattered throughout this area were numerous small and large, solid masses of pale cells, morphologically similar to islet tissue In other areas, the inner lining of the cyst was made up of stratified, columnar, ciliated epithelium, beneath which were a few small mucous glands in the stroma, suggestive of pharyngeal mucosal structures. In this general neighborhood were several small islands of hyaline cartilage and fatty tissue in the cyst wall, but no bone or dental structures were observed.

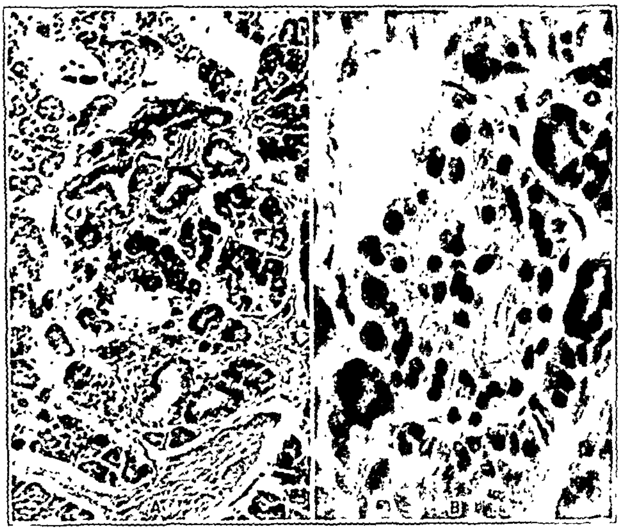

Fig. 3.—*A*, pancreatic glandular tissue and ducts; reduced from a photomicrograph with a magnification of 150 diameters. *B*, pancreatic islet and glandular tissue; reduced from a photomicrograph with a magnification of 500 diameters.

The middle zone of the cyst wall consisted of collagenous, fibrous tissue showing extensive hyalinization and areas of mucoid degeneration. In numerous areas there were irregular small and large collections of phagocytic cells containing yellowish-brown blood pigment and considerable lipoid material. A few scattered islands of perivascular lymphocytic infiltration were also found.

In the outer layers of the cyst wall, several centimeters from the site of the pancreatic tissue, there were small masses of lobulated, colloid thyroid tissue (fig. 4 *A*), with vesicles lined by flattened epithelium, and considerable thymic tissue containing Hassall's corpuscles (fig. 4 *B*). Some of the latter tissue extended well into the fibrous wall of the cyst and appeared to be somewhat compressed and atrophic. In such areas, Hassall's corpuscles were not present.

The most frequent location of intrathoracic dermoid cysts is the upper mediastinum. They are usually situated medially but may extend laterally so that the major portion of the mass appears to the right or left of the midline. Generally, they are entirely within the thorax, but in about 10 per cent of cases[1] a swelling is apparent in the neck. The tumors vary greatly in size and consist of simple epidermoidal components or complex teratomatous growths. The symptoms are chiefly those due to mechanical obstruction, to compression or to irritation of surrounding structures and are dependent largely on the size of the mass. The principal complication is infection, which may terminate in the formation of an abscess, with spontaneous rupture, mediastinitis, perforation of the trachea, emphysema, pneumonia or pulmonary abscess. Malignant neoplastic transformation occurs in about 15 per cent of cases.[2]

The literature concerning intrathoracic dermoid cysts has been reviewed by Kerr and Warfield,[1] Williams,[2] Hertzler,[3] Harris,[4] Hale[5] and others. These articles form a complete bibliography.

## COMMENT

The case reported illustrates how easily a mediastinal dermoid cyst may be mistaken for an intrathoracic goiter. The comparatively rare occurrence of the former as contrasted with the frequent occurrence of the latter lesion is probably one of the reasons why the differentiation is not made clinically more frequently. In cases of intrathoracic goiter, it is usually possible to detect a direct continuity between the thyroid itself and the mediastinal swelling. On the other hand, in 90 per cent of the cases reviewed in the literature, the mediastinal dermoid cyst is not in continuity with the thyroid. Therefore, demonstration of this continuity, or the absence of continuity, may prove to be a useful sign in making the correct diagnosis, although up to the present we have not had occasion to confirm this suggestion.

Misinterpretation of thyroidal and dermoidal lesions, at operation and on gross examination of the removed tissue in the laboratory, may occur also in another direction. A broken down, necrotic, cystic adenoma of the thyroid, whether cervical, partially or completely intrathoracic, may be mistaken for a dermoid cyst on account of the nature of the contents and the character of the cyst wall. Such tumors generally are a part of the thyroid, and microscopic examination after their removal suffices to make the distinction.

In the title the tumor is stated to be a dermoid cyst. Its very complexity, however, probably necessitates its being classified as a teratomatous cyst. Derivatives of three germ layers are represented, namely, stratified squamous epithelium and sebaceous glands; ciliated columnar epithelium and pharyngeal mucous glands; thyroid and thymus; pancreas; fat and cartilage.

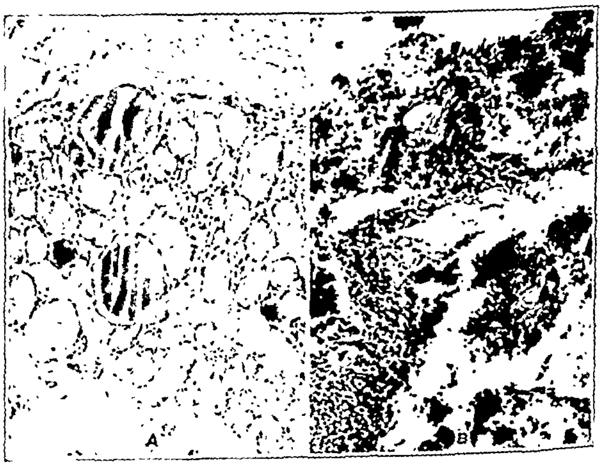

Fig. 4.—Section from the outer layer of the cyst wall: *A*, thyroid tissue; reduced from a photomicrograph with a magnification of 100 diameters. *B*, thymic tissue; reduced from a photomicrograph with a magnification of 150 diameters.

The branchial apparatus would seem to be the most probable source for the particular combination of tissues present in the cyst wall and the tumor may be looked on as an inclusion cyst. In this sense, it is not exactly comparable to those ovarian dermoids in which a totipotential germ cell is capable of differentiation in all the tissues of the body.

The thyroid tissue in the cyst wall in our case is probably of lateral branchial rather than of median pharyngeal origin. Its intimate association with thymic tissue would seem to warrant this conclusion. The occurrence of tissue having morphologic characteristics identical with those of the pancreas is of interest and has not been reported heretofore as occurring in a mediastinal dermoid, as far as we know. The presence of this tissue as a pharyngeal derivative is not so readily explained without invoking the theory of metaplasia. The salivary glands and the pancreas are physiologically related organs but originate at widely separated points in the entodermal tract. If the primitive pharyngeal epithelium can differentiate into such diverse organs as the salivary glands, the thyroid and the thymus, it is not inconceivable that the pancreatic tissue in our case may likewise be of pharyngeal origin.

As was noted in the case report, no significant disturbance of sugar metabolism was detected.

### SUMMARY

A dermoid cyst of the anterior mediastinum, extending into the neck and simulating a substernal goiter, was removed through a low collar incision as in thyroidectomy. Recovery was complete and the patient reported that she was in excellent health, one year following the operation.

The presence of histologically normal pancreatic tissue in the cyst wall makes this case unique.

# THE REPAIR OF UNUNITED FRACTURE OF THE NECK OF THE FEMUR

PAUL B. MAGNUSON, M.D.
CHICAGO

Probably no other common fracture has been so completely and consistently disabling as fracture of the neck of the femur, (1) because of the inability of bone to throw down sufficient callus to repair the fracture; (2) because most of the patients in whom the fracture occurs are in the latter part of adult life; (3) because it is apparently difficult to reduce the fracture and hold it in reduction; (4) because, owing to the age and weight of a great many of the patients, it is impossible at times to put on any fixation apparatus that is bearable. Therefore these fractures go to nonunion and deformity, with loss of carrying ability of the leg on the affected side and a serious and permanent disability which confines the patient to a limited area of activity.

Many operations have been advanced for the repair of these fractures. Murphy advocated the use of long spikes driven through the trochanter up into the neck of the femur after reduction. Later, an autogenous graft used in the same way was recommended by a number of surgeons, and, still later, Whitman and Brackett advanced operations that have not been sufficiently used. It seems incredible that one who is familiar with the pathology of old ununited fractures would choose to use a spike or autogenous bone graft as a spike to fasten the trochanter to the head through a mass of heavy fibrous tissue with the expectation of obtaining any considerable mechanical support. To begin with, the trochanter is pushed upward from three-fourths inch to 2 inches above the acetabulum; then there is more or less complete absorption of the neck so that the fixation appliance must bridge a considerable gap where there is no bone; the head is usually in a rotated position whereby the trochanter cannot be brought opposite the fractured surface; and, finally, after the displacement has occurred and contraction has taken place with the heavy fibrous tissue filling the gap between the trochanter and the head, it is impossible to pull the leg down far enough to bring the fractured surface on the trochanter and the fractured surface on the head opposite each other, to say nothing of bringing them into apposition. The ends of the fragments are covered with hard, smooth, fibrous tissue which has reached complete maturity, and to expect bone to grow from either end of the fracture is to expect the impossible: one might as well place two surfaces of skin together and expect them to unite without first abrading the surface.

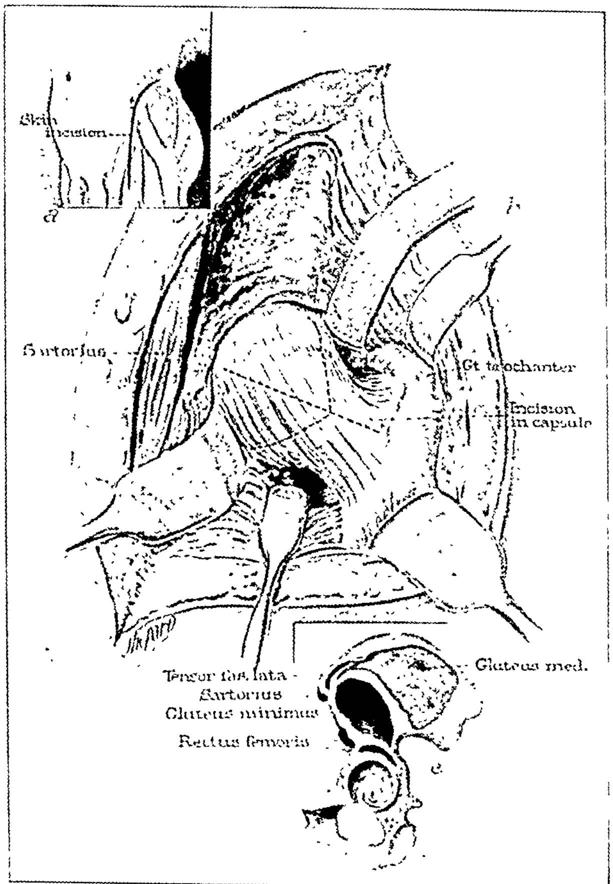

Fig. 1.—*a*, skin incision; *b*, exposure of joint capsule and lines of incision; *c*, origin of muscles around hip joint.

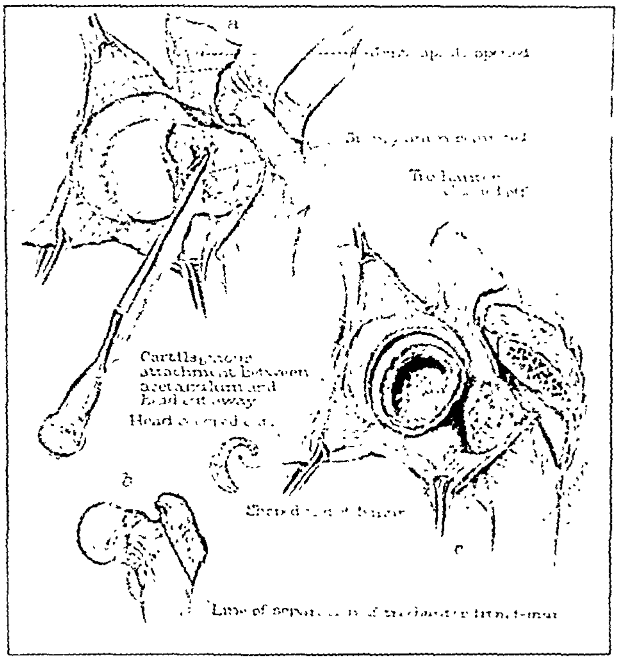
I have seen patients who have walked after such a nailing operation has been performed, but I have never seen anything in the roentgenogram following operation which would warrant the conclusion that there was a bridging by callus between the trochanter and the fractured surface of the head, and I believe that the patient's ability to walk occurs as the result of unusually heavy fibrous tissue formation between the trochanter and the acetabulum, forming a fibrous support which will hold more or less weight, depending on its density and the area over which it extends. I have never seen normal motion after such an operation, and it seems quite impossible, considering the shallowness of the head and the length of the gap to be bridged, plus the condition of the healed fractured surfaces, that any hope of a normal hip could be expected.



a
Cartilaginous attachment between acetabulum and head cut away
b
c

Fig. 2.—*a*, exposure of joint cavity and fibrous tissue, *b*, line of removal of trochanter; *c*, head and neck of femur shaped to fit each other.

Whitman recommended removal of the head, clearing of the scar tissue between the head and the trochanter, and the fitting of a remolded end of the shaft into the acetabulum. Brackett advocated an operation which in most cases, I believe, serves to reestablish anatomic relations better than any which have so far been advanced. The results have been so satisfactory to both patient and surgeon that it would seem that this operation should be more generally advocated.

Under this method I have done seventeen reconstructions of the hip joint, always with an open mind before the operation, making the decision between the Brackett and the Whitman operation after the condition of the head has been thoroughly investigated, as this decision is influenced by several important factors which come to view when the hip joint is exposed.

The incision follows a Smith-Petersen exposure along the anterior margin of the ilium, curving downward and forward along the inner border of the sartorius muscle; the muscle is split and the inner attachment of the quadriceps is cut transversely close to its attachment (fig. 1 *a*). The capsule of the joint is exposed and the fibers of this are seen to run, instead of downward and outward, either straight outward at right angles to the long axis of the body or sloping a little bit upward and outward (fig. 1 *b*). The capsule is split from the acetabulum to the trochanter with a scalpel, then cut crosswise near the edge of the acetabulum, as far around toward the posterior surface as possible (fig. 1 *b*). This gives thorough exposure of the mass of fibrous tissue contained within the capsule, which bridges the gap between the fractured surface on the head and the fractured surface on the trochanter. At this point it will be noted that there is more neck than the roentgenogram had disclosed, but in this series of cases the head did not protrude beyond the outer rim of the acetabulum, except in small jagged irregularities.

The fibrous tissue connecting the head and the trochanter was removed with heavy, slightly curved, round-pointed scissors, and this was one of the most difficult parts of the operation (fig. 2 *a*). After removal of the fibrous tissue, in ten of the seventeen cases the head was found to be tightly adherent to the edge of the acetabulum around this fractured rim and with difficulty was completely freed (fig. 2 *c*). By rotating the head in the acetabulum, all surfaces could then be inspected easily. The hardness of the head was tested by pressure with the point of a 6 inch hemostat. The fractured surface was rather soft in each case, but this softness extended only from one-eighth to one-fourth inch into the head, at which point rather compact bony tissue was encountered. In three cases the cartilage was yellowish; in all others it was the normal color of healthy hyaline cartilage. After thorough examination, the head was allowed to assume its normal position in the acetabulum, which is controlled under these circumstances by the ligamentum teres, so that an estimation could be made of the point at which the main weight-bearing of the shaft would occur in the reconstructed hip.

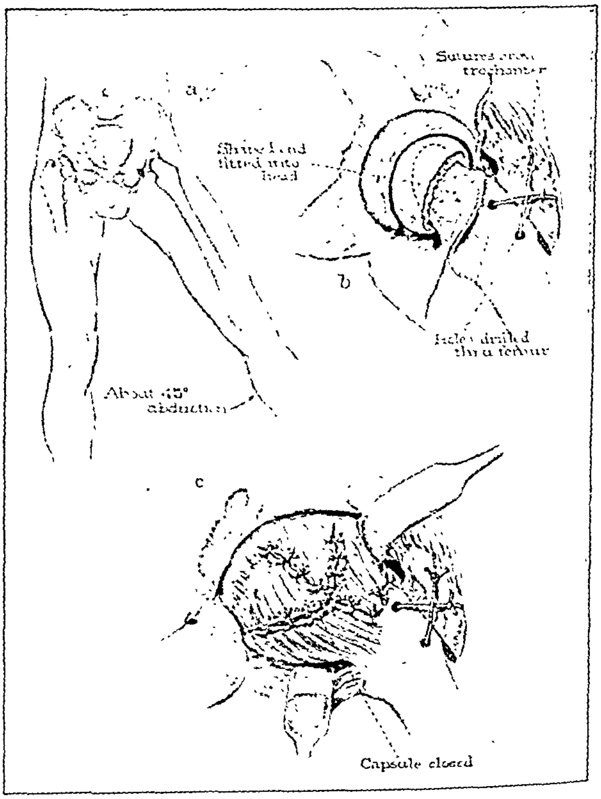


Fig. 3.—*a*, position in which leg is to be maintained after operation; *b*, normal relations of structures reestablished; *c*, completed operation.

With a large motor-driven burr the femoral head was hollowed out in the form of a truncated cone, the deepest portion of which was at the point where the greatest weight would fall with the patient in a standing position (fig. 2 *c*). This excavation was made down to a point where the bone of the head underlay the cartilage rather closely, and in all cases the bone was firm and hard at this point. This stage of the operation having been completed satisfactorily, the trochanter with attached muscles was cut off at an angle estimated to be the original angle of the neck; that is, the line of incision through the trochanter sloped downward and outward (figs. 2 *b* and *c*). A wide, thin-bladed chisel was found to be the best instrument; it was more adaptable than a Gigli saw, and, as free lateral approach was not possible because of the incision, it proved to be a better guide to the angle at which the trochanter was being cut.

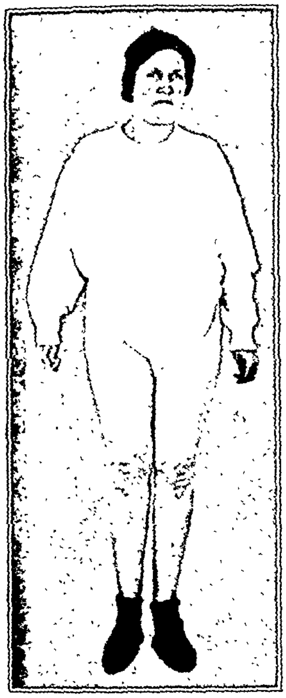

Fig. 4. — Woman, aged 49, operated on sixteen months after fracture because of nonunion; 1 inch shortening; no other disability. Appearance five years after operation.

This incision, at the upper end, was started exactly at the base of the neck of the femur, leaving intact whatever portion of the neck remained attached to the shaft; the upper end of the shaft with the remainder of the end of the neck, was then brought up into the incision and rounded off in the same curve which had been produced in hollowing out the head (fig. 2 *c*). It was found necessary in cases in which there was very little neck remaining to narrow the upper end of the shaft from front to back by removing the sharp edges left by the removal of the trochanter in order that it might not strike the edge of the acetabulum in flexion and extension. After the upper end of the shaft had been modeled to fit into the hollowed out head and had been narrowed by cutting away bone from the front and back edges of the shaft where the trochanter had been removed, a Murphy skid was placed against the upper rim of the acetabulum and over the upper end of the shaft, and the newly modeled neck was levered into its new position in the head. At the same time the leg was abducted, care being taken to rotate the shaft while abducting the leg so that the upper convex surface on the neck would fit into the concave surface cut to receive it in the head. In all cases in this series, the muscles originating on the pelvis and inserted in the femur and leg were sufficient to hold the end of the shaft snugly up into the acetabulum when the leg was held in about 45 degrees of abduction.

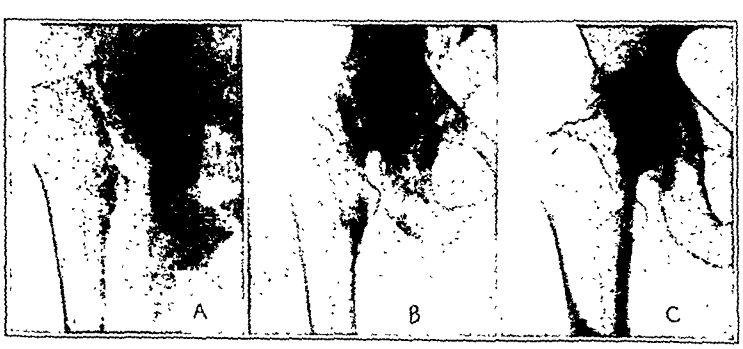

Fig. 5.—Fractured neck of femur in patient shown in figure 4: *A*, before operation; *B*, three months after operation; *C*, five years after operation. Note union and direct weight-bearing from shaft into head.

This accomplished, it was necessary to reattach the trochanter to the shaft of the femur. The trochanter has suffered, as has the rest of the bone, from atrophy of disuse and consequently is not a satisfactory area through which to pass the retaining sutures of malleable iron wire or silk used for fixation. Two holes were drilled through one side of the cortex of the upper end of the shaft and a suture inserted in each, which was brought out through the medullary cavity and carried up through the muscle attachments just at the tip of the trochanter (fig. 3 *b*). The trochanter was then pulled downward to come into a position below and lateral to its normal, the sharp, wedge-shaped lower end protruding beyond the shaft on the lower lateral border of the place from which it was removed.

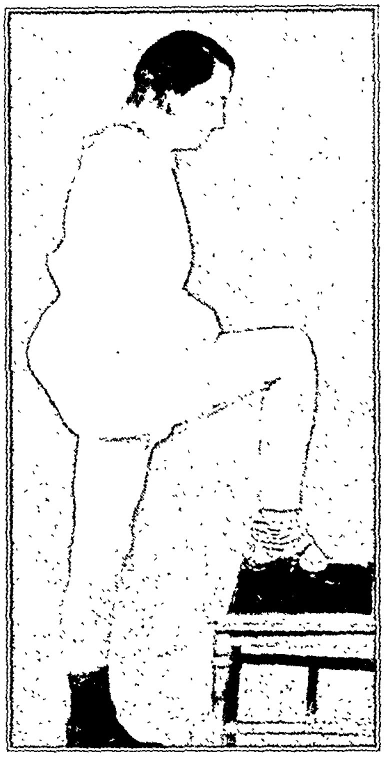

Fig. 6.—Woman, aged 52, operated on three weeks after fracture as choice between Whitman closed method and open operation. Patient left hospital seventy-four days after operation, bearing weight. Three-fourths inch shortening two years after operation; no other disability; no limp. This is the only patient we have operated on for any cause other than nonunion.

The normal relations of the hip joint being practically reestablished, the muscle attachments were all in place and had a constant tendency to hold the upper end of the shaft firmly into the head (fig. 3 *c*). The head with its smooth hyaline cartilage moved freely in the acetabulum and followed the motions of the shaft of the femur because of the firmness with which the shaft was held against it, or actually reposing within it. In no instance was the patient placed in a cast, it being necessary only to hold both legs in 45 degrees of abduction, which can be done with a Ranney splint; in this way the discomfort resulting from fixation in a cast was avoided. The legs were flexed as much as 45 degrees. After two weeks of immobilization the patient was allowed to semirecline in bed and was given complete sponge baths.

During the first eight weeks of convalescence, two points that cannot be overemphasized are: (1) The legs must be maintained in at least 45 degrees of abduction; (2) the affected leg must be fixed continuously in a position of internal rotation. If these two positions are maintained, the hip can be moved and the patient can be moved in bed. Such fixation is necessary for eight weeks only, at the end of which time the patient can be allowed up in a wheel-chair and on crutches. Weight-bearing can be started as soon as the patient is out of bed. Bony union is not necessary, because the upper end of the shaft and the head become firmly adherent in eight weeks, and, as weight-bearing tends to force the shaft further into the head, walking is advisable.

The surprising feature in this operation is that it seems to involve comparatively slight surgical shock. The youngest patient of this series was 47, the oldest 85 years of age. There were no deaths and no cases of serious postoperative shock. The results were uniformly satisfactory to the patient. The time between the date of fracture and operation varied from six months to seven years in all excepting one case (fig. 6). In only one case was it necessary at the time of operation to remove the head. This patient, the youngest in the series, had been disabled for seven years; the head was so degenerated that it was useless, and a Whitman operation was performed.

### CONCLUSIONS

Because of the large mass of fibrous tissue present in this type of case, nailing and the usual form of autogenous graft fixation is unsatisfactory in most cases.

The fractured surface of the trochanter cannot be brought opposite the fractured surface of the neck because of the mass of fibrous tissue.

New bone will not form in hard, old scar tissue, and fractured surfaces covered with old fibrous tissue will not produce new bone.

It is necessary to remove the fibrous tissue between the head and the trochanter completely before new bone will form; this can be done only by opening the capsule.

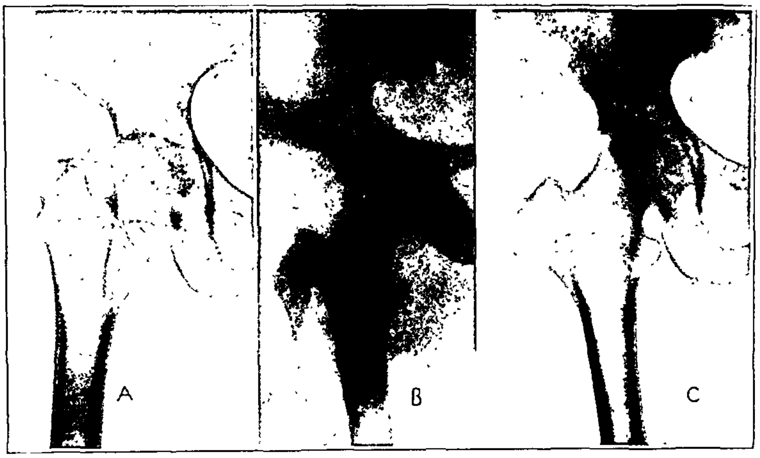

Fig. 7.—Fractured neck of femur in patient shown in figure 6: *A*, before operation; *B*, immediately after operation; *C*, two years after operation.

This operation reestablishes as nearly as possible normal anatomic relations, leaves the head covered with normal cartilage in contact with the normal cartilage of the acetabulum, and therefore results in a painless hip with much freer motion than can be obtained by any other method.

There is little surgical shock connected with the operation, and in patients of normal expectancy it can be performed without fear.

# ENCEPHALOGRAPHY UNDER NARCOSIS PRODUCED BY NONVOLATILE ANESTHETICS

## A NOTE ON THE TECHNIC

H. C. SOLOMON, M.D.
AND
S. H. EPSTEIN, M.D.
BOSTON

Our purpose in this paper is to discuss the use o nonvolatile anesthetics in the performance of encepha lography or pneumorachicentesis. By these terms i understood *the introduction of air through the lumba puncture needle, displacing fluid in the ventricular an subarachnoid systems and subsequently the making o roentgenograms of the head. This is in contradistinc*tion to the method of ventriculography, in which the skull is trephined and air is introduced directly int the ventricles.

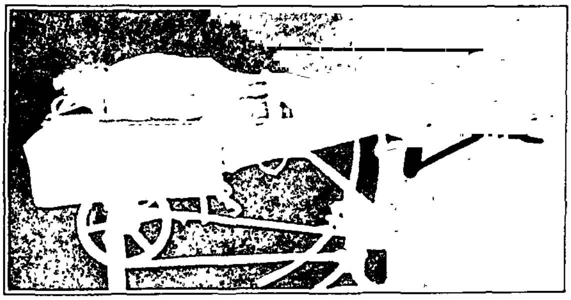

Fig. 1.—Patient lying supine on the stretcher.

Encephalography is largely replacing ventriculography because of the greater simplicity of the procedure, i. e., the necessity of trephining the skull being obviated. By many it is considered a somewhat less dangerous procedure, although about this there is considerable question.

The chief objection to encephalography is the great discomfort experienced by the patient, especially during the injection of the air. As a rule, after from 30 to 40 cc. of air has been injected, the patient complains of headache which grows more and more severe and which, from all appearances, is quite extreme. At about this time marked sweating occurs and the pulse becomes slow, dropping to 60, 50 and occasionally even as low as 40 beats a minute, and at the same time the quality becomes rather poor. As the injection of air continues, vomiting of the projectile type frequently occurs. As the amount of air required to give adequate roentgenograms is from 100 to 200 cc., and as this must be injected moderately slowly, it takes from fifteen minutes to half an hour to carry out the procedure. This is, of course, a long period of suffering for a patient unless alleviated by some means. It is also a difficult period for the operator. At times the procedure has to be stopped before the required amount of air is injected because of collapse or near collapse of the patient. Following the encephalography, headache usually continues for a number of hours and not infrequently for a day or two.

---

From the Boston Psychopathic Hospital.

Because of these reactions, various measures have been utilized, tending to mitigate the severity of the reaction and to make the procedure less disturbing. Morphine and scopolamine are used frequently; while these drugs greatly diminish the discomfort, they by no means entirely overcome it, and there are obvious disadvantages of using these drugs in the high dosage that is necessary to give reasonable relief. Volatile anesthetics, especially ether, have been satisfactorily employed. There are, however, several disadvantages to them; namely, the possibility of pulmonary complication, the marked increase in intracranial pressure which is a contraindication in cases of pathologically increased intracranial pressure, the unpleasant after-effects of the anesthesia, and the need of an anesthetist. Hence we have turned to the use of nonvolatile anesthetics such as sodium ethyl (1-methyl-butyl) barbiturate (pentobarbital-sodium), sodium isoamylethyl barbiturate (amytal), and avertin. These drugs have the advantage of a quickly induced anesthesia with no markedly unpleasant after-effects, no rise in intracranial pressure, a fairly prolonged analgesic effect after the anesthesia has worn off, ease of administration, and relative safety.

Our experience has been obtained chiefly with pentobarbital-sodium. However, we believe that what can be said about the use of this drug is equally true of sodium isoamylethyl barbiturate, as we have used the latter preparation for anesthesia for other purposes, and the clinical and physiologic results are very similar.

Our procedure is to give an intravenous injection of from 0.3 to 0.5 Gm. (from 5 to 7½ grains) of pentobarbital-sodium dissolved in from 10 to 15 cc. of distilled water. The solution is injected slowly, from three to five minutes being taken for the injection. The patient is usually in a state of narcosis by the time the injection is completed. Occasionally a subcutaneous injection of 0.16 Gm. of morphine sulphate is given fifteen minutes before the pentobarbital-sodium. The narcosis obtained is quite profound. The deep reflexes are abolished, as are the skin and gag reflexes. This state of areflexia and complete anesthesia is obtained in from ten to twenty minutes after the injection, and the patient is then ready for the encephalographic procedure.

As the patient is in a state of muscular relaxation, it is convenient to have an apparatus that will hold him in position for the air injection. It is quite practical to get along without any special apparatus by placing the patient on a stool, allowing the body to rest on a padded table with support given on either side by a nurse, attention being given to the support of the head. However, we have found it more convenient and practical to use the apparatus to be described.[1]

This apparatus consists of a jointed stretcher which may be placed on the operating table; the anesthetic is administered while the patient is lying supine on the stretcher (fig. 1). About midway along each side of the frame there is a joint with a semicircular disk containing a number of holes into which pins may be placed. In this way various angles of the sitting position may be obtained (fig. 2). The patient is held in place by a head sling, two shoulder straps hung from the top of the frame, and an abdominal strap fastened to the sides (fig. 3).

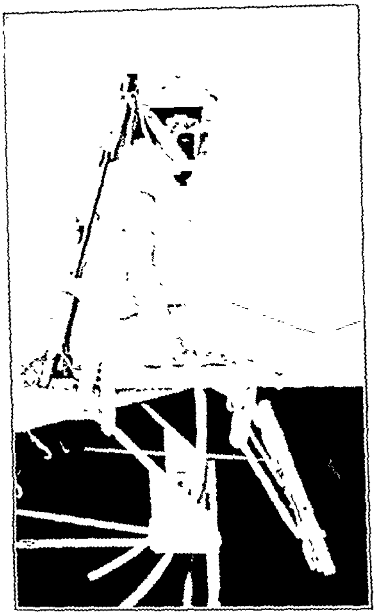

Fig. 2.—Patient in sitting position, held by sling, shoulder and abdominal straps.

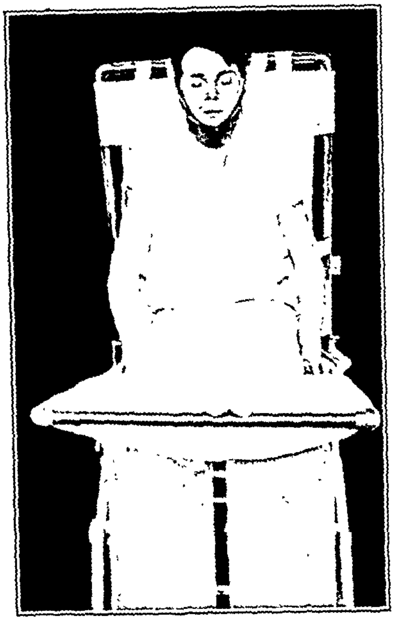

Fig. 3.—Front view of chair.

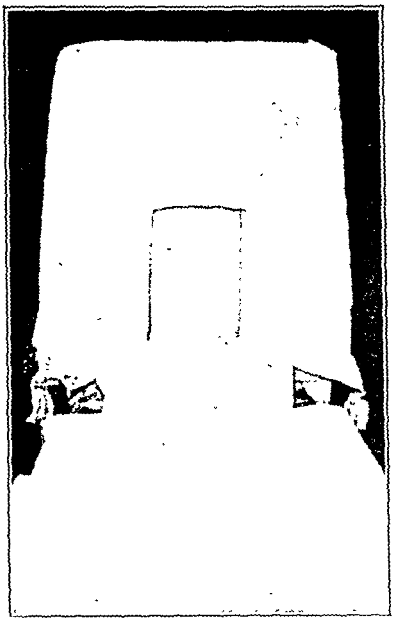

Fig. 4.—Back view of chair, showing opening for lumbar puncture.

The lumbar puncture and the air injection are made with the patient in an upright position through a rectangular opening in the canvas which forms the back of the apparatus (fig. 4).

In order to get the best filling of both the subarachnoid space of the head and the ventricles, it is necessary to be able to shift the position of the patient from time to time. Thus, with the head and trunk in an erect position, the best filling of the ventricles is obtained, whereas with the head and trunk bent forward or backward, the subarachnoid spaces are more readily filled. It is also advisable to move the head from side to side and backward and forward at the neck. These changes of posture are easily produced with this apparatus. The head sling allows for easy movement of the head by an assistant, and the angle of the back-rest is readily changed.

---

[1] This table was designed for use in encephalography under anesthesia by Drs. S. H. Epstein and S. S. Hanflig.

When the air injection has been completed, the patient may be wheeled to the x-ray apparatus either sitting upright or recumbent, and the pictures may be taken in the vertical or the horizontal position as thought best by the roentgenologist.

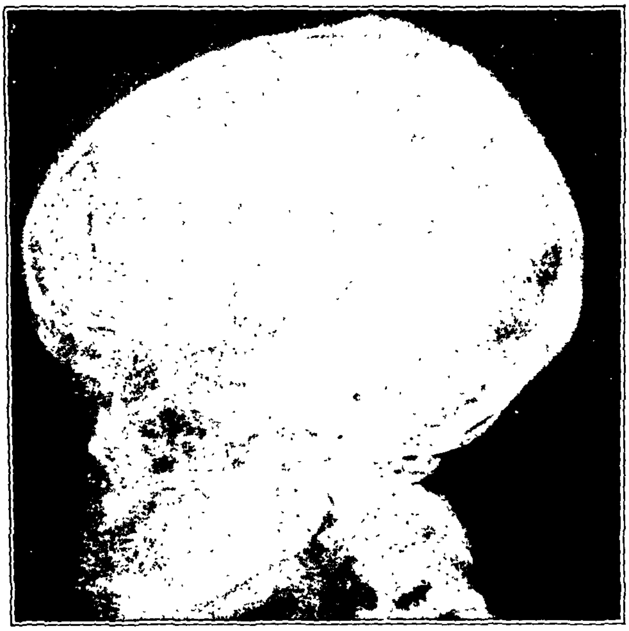

Fig. 5.—Lateral view showing a normal encephalogram.

As already mentioned, the air injection usually takes from fifteen to thirty minutes. During this period the patient is completely anesthetic, the operator is not disturbed by complaints from the patient, and the injection is not interrupted, nausea and vomiting do not occur, and there is practically no diaphoresis. The roentgenograms are made with the patient in a state of anesthesia which enables one to put the head in any desired position; no vomiting occurs, as is frequently the case when an air injection is performed without anesthesia, and thus the roentgenologist has no interference with his technic from the patient. In dealing with psychotic, disturbed or fearful patients, this is of especial advantage.

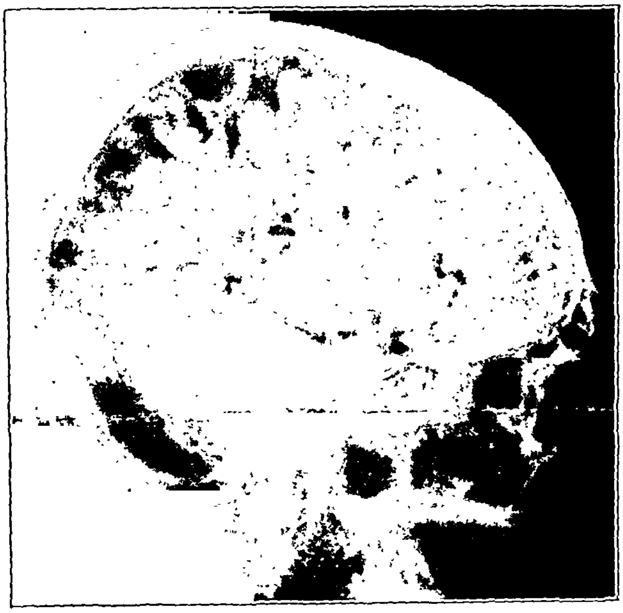

Fig. 6.—Lateral view showing extensive cortical atrophy and enlargement of the lateral ventricles.

The narcosis gradually wears off in the course of from four to six hours. On awakening, the patient rarely has a complaint and usually is able to take nourishment. There are, as a rule, no headache, no gastro-intestinal symptoms, and no fever. Headache frequently does occur some hours later, but at this time it is rarely very severe and is easily controlled by a moderate dose of some opiate.

With avertin anesthesia, the conditions are very similar both as to the condition while the air is being introduced and as to the after-effects.

We have encountered no special contraindications to the use of pentobarbital-sodium anesthesia in cases selected for encephalography. We have employed this drug in twenty instances, mainly in cases with symptoms of intracranial pathologic conditions other than those of tumor. Figures 5 and 6 show the roentgenographic results of the technic as described in this paper with pentobarbital-sodium anesthesia.

# ROENTGEN VISUALIZATION OF LYMPH NODES IN ANIMALS

## PRELIMINARY REPORT

LEON J. MENVILLE, M.D.
AND
J. N. ANÉ, M.D.
NEW ORLEANS

As is well known, the lymphatics will absorb particulate substances, and also materials insoluble in water, whereas the blood capillaries are principally concerned with the absorption of materials soluble in water. This knowledge has resulted in much interesting experimental work bearing on the subcutaneous injections of certain insoluble materials which were found to have been taken up by the lymph vessels and carried to the lymph nodes. Many investigators have reported certain experimental results obtained by injecting insoluble substances, such as carbon and carmine, into the subcutaneous tissues of the legs of animals. They have been able to prove, by recovering them in the lymph nodes, that the lymphatic system absorbed these substances. While such results are interesting and important, we are unable to find experimental use of the roentgen ray in the living animal to visualize foreign opaque particles in lymph nodes. The collection of iodized poppy-seed oil in the lymph spaces of the neck and head was observed by Pfahler[1] one year after the injection of the antrums by this opaque medium for the purpose of studying the sinuses. He was of the opinion that his case was the first roentgen demonstration of the lymph spaces. He was unable, however, to demonstrate the lymph glands or nodes. Our review of the literature would indicate that this presentation of experimental work on the visualization of lymph nodules of animals is the first roentgen demonstration of this important unit of the lymphatic system.

While conducting certain experimental work on animals by injecting thorium dioxide into the tail veins

[1] Pfah[illegible] the Lymphatic Drainage from the Maxill[illegible] 27: 352-356 (March) 1932.

of rats, visualizing the liver, spleen and kidney with their vessels, we were unsuccessful in several instances in injecting the material into the vein. This was particularly true in the tail vein of rats, and in these instances a small amount of the thorium dioxide was injected into the tissues surrounding the blood vessels. In such instances, it was observed at a later time that a roentgenogram disclosed the lymph nodes clearly visualized.

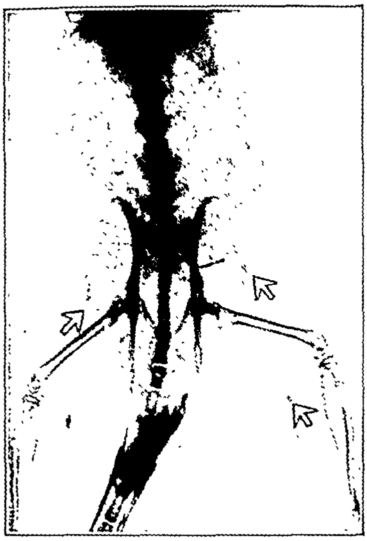

Fig. 1.—The popliteal and inguinal nodes and also a vessel leading from the tail of the rat to one of the lymph nodes.

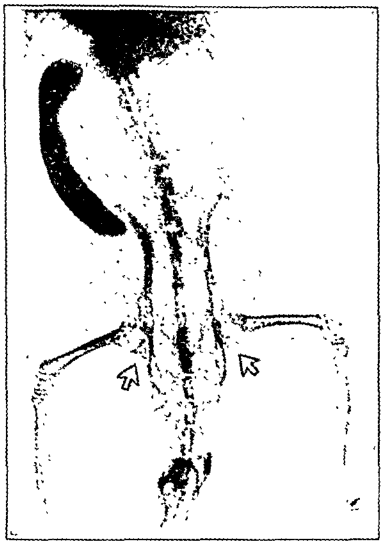

Fig. 2.—Visualization of inguinal lymph nodes with vessels. This rat was previously injected intravenously to visualize the liver and spleen. The inguinal lymph nodes were visualized, however, by subcutaneous injection with thorium dioxide.

The following experiments were conducted on the white rat and the dog to ascertain whether lymph nodes could be visualized in every instance and in different locations. Twelve white rats and one dog were used in these experiments. They were all injected with 0.1 to 0.25 cc. of thorium dioxide in the tail and legs, as near blood vessels as possible without introducing the material into them. These areas were chosen because of the prevalence of perivascular lymph spaces. It was found that visualization was produced more rapidly from this vicinity than when injections were made in other less vascular areas. Roentgenograms were made of each animal every twelve hours, and in every instance the lymph nodes were visualized in the region near the injections in from one to three days. These visualizations include popliteal (fig. 1), inguinal (fig. 2), axillary (fig. 3), and mesenteric (fig. 4) glands. Among the rats used, two were pregnant, and in both instances the lymph nodes were visualized much earlier and with greater density than in the nonpregnant rats. These subcutaneous injections of thorium dioxide have never produced any slough, abscesses or harmful effects. It is now more than two months since some of the animals were injected, and the thorium is still visible at the site of injection.

In order to be certain that the objects demonstrated on the roentgenograms were lymph nodes, we removed several of the lymph nodes and examined them by means of the roentgen ray. The marked density of these nodules left no doubt in our minds that they were impregnated with thorium. In the instances wherein we used a dog, injected in the same manner as the rats, a similar visualization of the inguinal lymph nodes was apparent (fig. 5). We removed these (fig. 6), and a histologic examination by Dr. W. H. Harris of the Department of Pathology, Tulane University of Louisiana School of Medicine, showed conclusively that the lymph nodes had absorbed a large quantity of thorium.

We are at present conducting similar observations on man and our encouraging results indicate that an early report on this subject will follow. Other experimental work is now under way in which the visualized lymph nodes are being studied to ascertain whether or not the radioactivity of thorium alone is sufficient to produce biologic changes; also whether the characteristic rays of thorium, when hard roentgen rays are applied to it, will be a factor in producing changes in the tissues of lymph nodes. If this can be shown to be the case, it will serve to stimulate investigation as to the greater effect that radiation therapy might have on malignant nodules impregnated with thorium. We are at present beginning such a study, to be reported later.

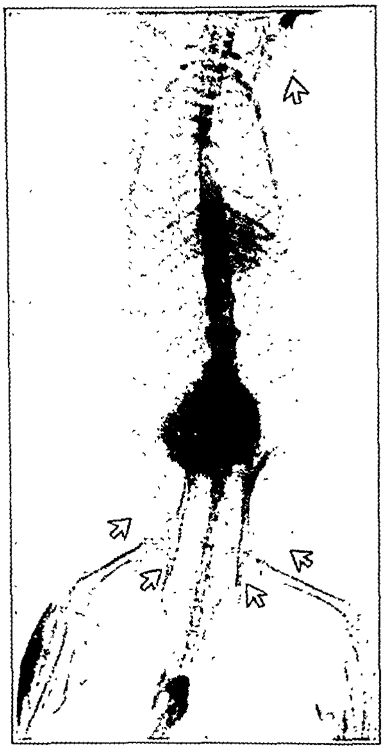

Fig. 3.—Visualized lymph node in the axillary space.

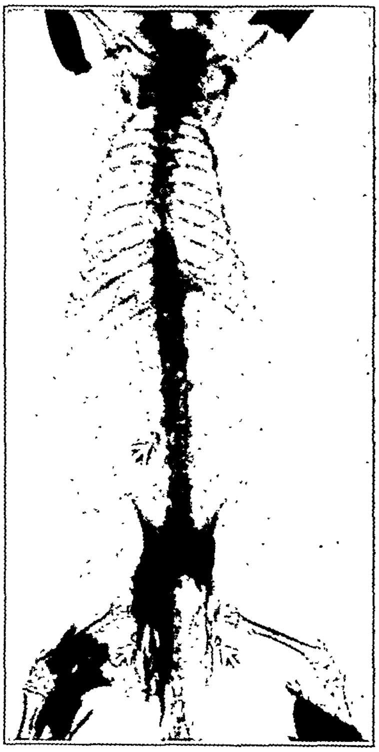

Fig. 4.—Visualization of the mesenteric lymph node and also inguinal lymph node.

The visualization of lymph nodes has two outstanding possibilities: namely, diagnostic and therapeutic. From a diagnostic standpoint, it can be appreciated that the possible visualization of lymph nodes in man could be of invaluable assistance to the surgeon in locating metastatic nodules before and after operation. From the therapeutic point of view, because lymph nodes absorb the metal thorium, which is radioactive and emits characteristic rays, it is possible that the efficacy of radiation therapy in cancer may in the future be greatly enhanced.

# SKIN ERUPTIONS FROM BISMUTH THERAPY IN SYPHILIS

EDWARD A. SKOLNIK, M.D.
AND
IRMA ALESHIRE, M.D.
CHICAGO

With the increasing use of bismuth compounds in the treatment of syphilis, various skin eruptions due to the drug have been observed. A few examples are recorded in the American literature and a larger number are reported by foreign writers.

Among the acute types of eruptions described are the erythrodermatous and exfoliative,[1] scarlatiniform,[2] hemorrhagic,[3] urticarial[4] and those resembling erythema multiforme.[5] Both Lehner[6] and Boas[1] have reported herpes zoster at the site of a bismuth injection.

The chronic forms observed were the eczematous and maculosquamous.[7]

During the past three years, approximately 25,000 intramuscular bismuth injections have been given at the Central Free Dispensary of Rush Medical College. Twenty-two cases of bismuth eruption occurred during this time. The diagnosis was established in most of the patients by (1) development of the eruption during the administration of bismuth; (2) subsidence of the rash on discontinuing the drug; (3) recurrence of the lesions on readministering bismuth.

The first case to be recognized is reported here in full, because the diagnosis was not established until after the appearance in the same patient of eruptions resembling three common skin disorders.

CASE 1.—A Jewess, aged 35, with latent syphilis, received sixteen weekly injections of potassium bismuth tartrate in oil with no untoward reaction to the drug. Six neoarsphenamine treatments, followed by eighteen injections of water soluble bismuth sodium tartrate, were given. After the sixteenth bismuth treatment, she presented numerous coin-sized, oval, fawn-colored, scaling macules which followed the cleavage planes of the skin on the neck, trunk, arms and thighs. This was pruritic and was considered to be pityriasis rosea.

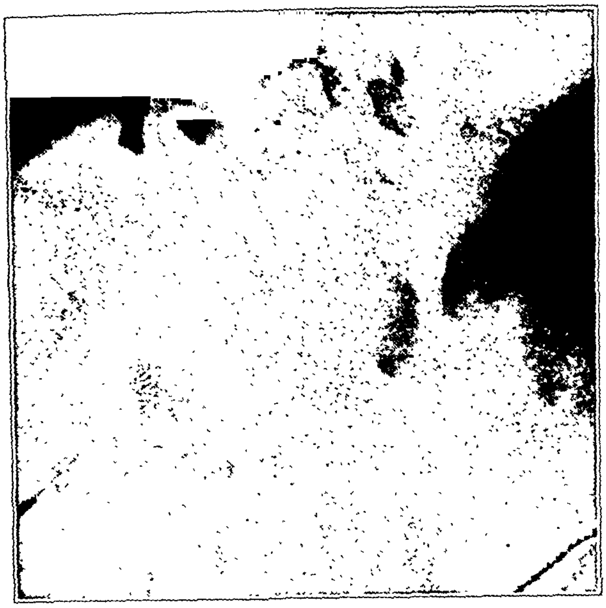

Fig. 1 (case 1).—Patches of lichenified dermatitis and pigmented relics of old lesions on the chest and neck during the third attack of bismuth dermatitis

Marked improvement in the lesions occurred during six weeks' rest and six subsequent neoarsphenamine treatments. Three weekly potassium bismuth tartrate injections were followed by the appearance of generalized, papular, lichenoid patches, from 0.5 to 3 cm. in diameter. Many of the lesions were pigmented. A diagnosis of lichen planus was considered; but under a presumptive diagnosis of a lichenoid neoarsphenamine rash, bismuth was discontinued and fifteen daily intravenous treatments of 1 Gm. of sodium thiosulphate were given. Because of only slight improvement, a diagnosis of lichen planus was made and mercuric chloride administered intragluteally for three months. The lichen planus-like patches disappeared, leaving pigmented relics.

After a rest, neoarsphenamine was given guardedly without mishap for a total of ten injections. It was then felt certain that she was not sensitive to this drug, but possibly to bismuth. After fourteen weekly bismuth treatments new lesions appeared in the pigmented relics of many of the old patches (fig. 1). These were fewer, larger, and of an acute eczematous nature with lichenification supervening. It was now decided that this and all previous eruptions had been caused by bismuth. She slowly recovered under intravenous sodium thiosulphate therapy. A test injection of bismuth caused a reactivation of some of the eczematoid lesions.

The patient's general health remained good throughout the entire period of observation. Urinalyses were invariably negative. A biopsy (fig. 2), done at the time of the lichen planus-like eruption, showed a nonspecific type of inflammatory reaction, with collections of small round cells immediately under the epidermis and about the blood vessels of the cutis.

There were thirteen patients, seven of whom were Negroes, who presented acute, erythematous, scaling, oval patches, following the cleavage planes of the skin and simulating the lesions of pityriasis rosea. Of these, seven were proved to be due to bismuth by withdrawal of the drug, administration of sodium thiosulphate, and recurrence of the lesions on the readministering of bismuth.[8] The following history is typical of this type of bismuth eruption.

CASE 2.—A white man, aged 31, with secondary syphilis, received ten neoarsphenamine and fifteen potassium bismuth tartrate injections, and a course of mercury rubs. Then, six neoarsphenamine and five bismuth treatments were given, when a mildly pruritic, pityriasis rosea-like exanthem appeared over the thorax and the arms (fig. 3). This eruption practically disappeared after four intravenous treatments of sodium thiosulphate, and promptly reappeared at the old sites following two injections of bismuth. The eruption again cleared and reappeared in an aggravated form following five treatments of bismuth salicylate in oil. This patient had three attacks of bismuth dermatitis, provoked by two different preparations of bismuth in oil.

In several instances, this acute type of pityriasis rosea-like rash became chronic and lichenified, as the result of scratching. However, all cleared up as soon as the bismuth depots in the body had been eliminated. Soothing, oily lotions were the only local medication used in these cases.

In several instances, in which the patient was intolerant to mercury or the eruption mild, bismuth was given cautiously as the only intramuscular medication. In some, a mild dermatitis persisted throughout bismuth therapy. In others, gradual desensitization to the drug and complete disappearance of the rash occurred during treatment. Case 3 is illustrative of this desensitization:

CASE 3.—A Negro, aged 40, with secondary syphilis, developed an acute, patchy, erythematosquamous rash, scattered sparsely over the arms, chest, abdomen, thighs and legs, following the first course of neoarsphenamine and bismuth. The rash subsided during a rest and a course of neoarsphenamine. After the fourth injection in a new series of bismuth treatments, he developed a slight stomatitis and an exacerbation of a moderate number of the old lesions. A severe mercurial stomatitis and diarrhea occurred on three separate occasions when mercury was substituted for bismuth. For this reason, bismuth was used thereafter, in spite of the known bismuth sensitivity. The lesions persisted in a lichenified form during a twelve weeks' course of bismuth.

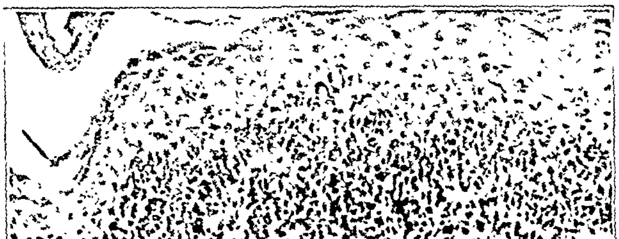

Fig. 2 (case 1).—Section taken at biopsy during the second attack of dermatitis, which shows the nonspecific character of the inflammatory infiltrate of a papule.

After a rest and a neoarsphenamine course, the skin was normal, excepting for pigmented relics of the patches. Following the twelfth bismuth treatment in this course, a mild lichenified recurrence appeared with no accompanying stomatitis. Later, a fourth course of bismuth produced no skin reaction whatever. While this patient was becoming desensitized, there was no change in the kind of drug used.

---

[8] Since this paper was accepted for publication, two more of the pityriasis rosea-like eruptions have been proved by our three criteria to be due to sensitivity to bismuth.

In one case the patient had an erythematosquamous eruption with acute urticaria preceding it. This was the only urticarial reaction from bismuth in our series and was identical with a case reported by Courcous and Boutelier.[9]

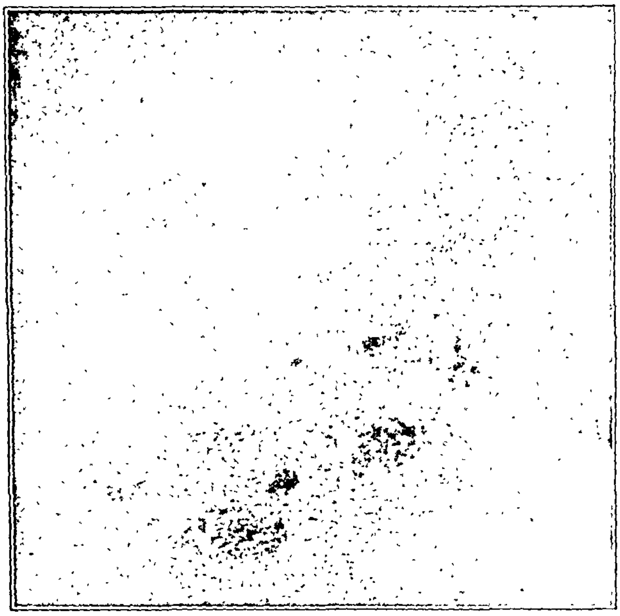

Fig. 3 (case 2).—Acute pityriasis rosea-like, oval, scaling patches on the anterolateral chest wall.

Case 4.—A young adult Negro with secondary syphilis received a course of neoarsphenamine and three injections of potassium bismuth tartrate, when an eruption appeared on the thorax and the abdomen. He did not report this until immediately after receiving the fifth bismuth treatment. At this time, he had maculosquamous lesions interspersed with acute, urticarial wheals, about 18 mm. in diameter, on the lateral and anterior aspects of the trunk. He stated that the wheals appeared first and developed into a scaling patch. Twenty-four hours later, many new wheals, severe nausea, and a moderate jaundice had appeared. Urinalysis was negative for sugar and albumin. Sodium thiosulphate cleared up the condition, after which he disappeared from observation.

In cases 5 to 14, inclusive, relatively mild erythematosquamous eruptions of a pityriasis rosea-like type were present. Of these, five proved to be bismuth sensitive according to the three criteria previously outlined. The diagnosis in the other cases was made from the occurrence of the distinctive rash during bismuth therapy. Except for one case of moderate stomatitis, there was no evidence of injury to the body associated with the dermatitis from bismuth in cases 5 to 14.

One instance of a lichen planus-like bismuth eruption appeared in the following case:

Case 15.—A white man, aged 30, with latent syphilis developed, during bismuth therapy, an eruption on the flexor aspects of the forearms and wrists. It consisted of small, polygonal, violaceous, flat-topped papules, indistinguishable from lichen planus. The patient had three different attacks of this dermatitis while receiving bismuth, the first clearing up with mercury therapy under a mistaken diagnosis of lichen planus. The second was recognized as a bismuth exanthem, disappearing with the use of sodium thiosulphate. The third attack was deliberately precipitated as a test.

In patients 16 and 17, one, a Negress, and the other, a white woman, a pruritic, generalized, fine, horny, folliculopapular eruption appeared. In the Negress, the eruption was so benign that two courses of bismuth were given, even though the rash persisted throughout treatment. In the white woman, the eruption tended to become more severe and exfoliative, precluding the use of bismuth. This was the second case in the series caused by bismuth salicylate. It was the only case of exfoliative dermatitis in our group, in contrast to the great number of these reported in the literature.

Patients 18 to 22 inclusive, two of whom were Negroes, developed a lichenified dermatitis, simulating lichen simplex chronicus, during treatment with bismuth. As in the previous cases, the patches subsided during rest periods and reappeared on subsequent therapy with bismuth. The patches were not very numerous and appeared on the neck, forearms and legs as pruritic, oval, pigmented, lichenified lesions up to the size of a palm (fig. 5). When seen early in their evolution, these patches presented vesicles with oozing and crusting. Three patients of this group never received neoarsphenamine from us. Two of the cases proved to be bismuth eruptions by fulfilling the criteria previously outlined.

## COMMENT

In all the cases here reported, the eruptions that developed as a manifestation of bismuth sensitivity had never previously appeared in these patients. The exanthems occurred during the administration of bismuth and ceased after the withdrawal of the drug, though some of the common skin disorders which they simulated are notably refractory to therapy. Since the eruptions in this series were so benign and resembled some of the usual skin diseases, we felt justified in

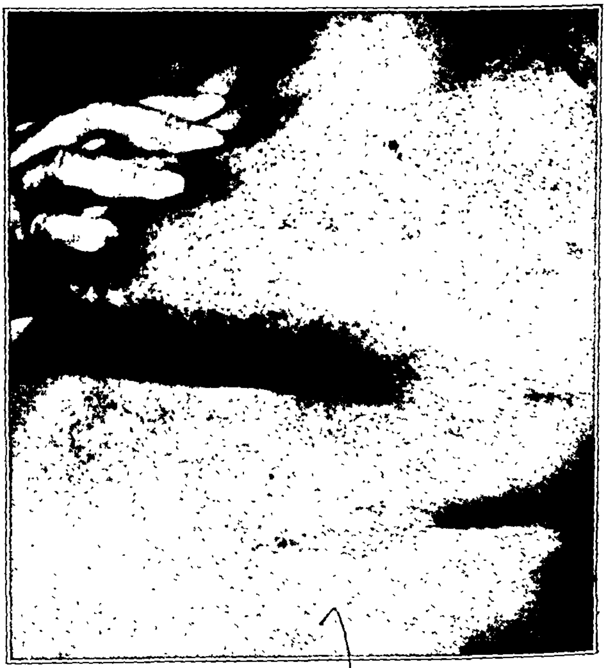

Fig. 4.—Same type of eruption as in case 3 on the skin of a Negress.

---

[9] Courcous and Boutelier, A.: Eruption pigmentée survenue au cours d'un traitement arsenico-bismuthique, Bull. Soc. franç. de dermat. et syph. 31: 59, 1924.

reproducing the condition a second or even a third time to prove the etiologic rôle of the bismuth. Thirteen of the cases were tested and proved in this fashion.

The mildness of the eruption is best illustrated by those cases in which the use of bismuth was continued in spite of the sensitivity, some of these patients gradually becoming desensitized. In contrast to these cases, there are reports in the literature of cases comparable in severity to those of arsphenamine dermatitis.

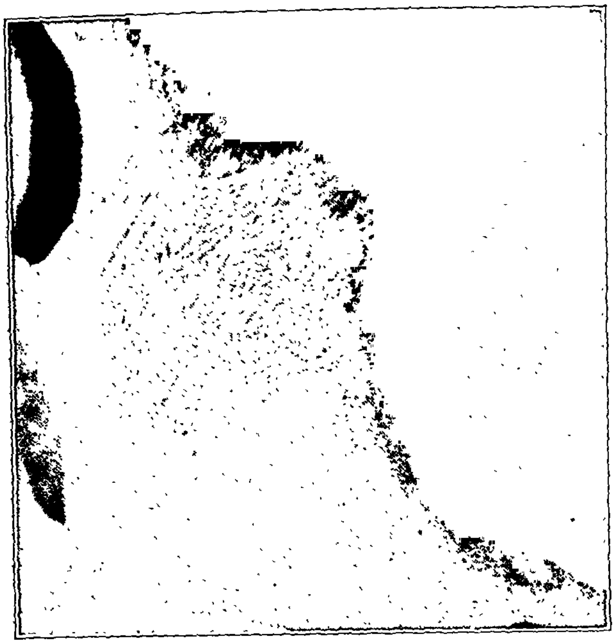

Fig. 5 (case 18).—Lichen simplex chronicus-like bismuth dermatitis on the neck.

The acute types of rash produced were the urticarial, folliculopapular, exfoliative, and the erythematosquamous, which resembled pityriasis rosea. The chronic types were the lichen planus-like and the chronic lichenified form, simulating lichen simplex chronicus. By far the greater number, fourteen, were in the pityriasis rosea-like group.

The incidence of skin reactions was approximately 1 in 1,140 bismuth treatments. Of the twenty-two cases reported, ten were in the Negro race, which is a much higher incidence than in the white race, considering the relative attendance of the two in the syphilis clinic. Reactions occurred with all the preparations used, which were an oil suspension of potassium bismuth tartrate, an aqueous solution of bismuth sodium tartrate, and an oil suspension of bismuth salicylate. The eruption was reproduced in several instances by a different preparation of bismuth, indicating that the sensitization was to bismuth alone.

These reactions developed in patients undergoing treatment for all stages of syphilis. In no case was there sensitivity to neoarsphenamine, although one man showed a marked sensitivity to mercury. Other than the skin lesions there were no subjective or objective manifestations attributable to the bismuth, except in two cases with moderate stomatitis and in another case with severe nausea and icterus. No serologic change attributable to the nonspecific action of the eruptions (esophylaxis) was found after their healing.

# NONRACHITIC CUPPING OF LONG BONES IN THE NEW-BORN

## A ROENTGENOLOGIC AND CLINICOPATHOLOGIC STUDY

JOHN T. FARRELL, Jr., M.D.
PHILADELPHIA
AND
EDWARD F. BURT, M.D.
ARDMORE, PA.

The possible existence of congenital rickets and its recognition have been much discussed. The problem has been approached from both the roentgenologic and the histologic angles, but little attempt has been made to correlate the observations of one with the other. Ylppö,[1] in a roentgenographic investigation of eighty-eight premature infants, believed that evidence of rickets was present in the long bones of five. Hess and Weinstock,[2] in a similar study of 250 new-born infants, found fraying with a tendency to cupping in the ulnas in a few instances, but they were unable to find a frank case of congenital rickets. Histologic studies carried out by Schmorl[3] on a series of over 100 full term and premature infants failed to show evidence

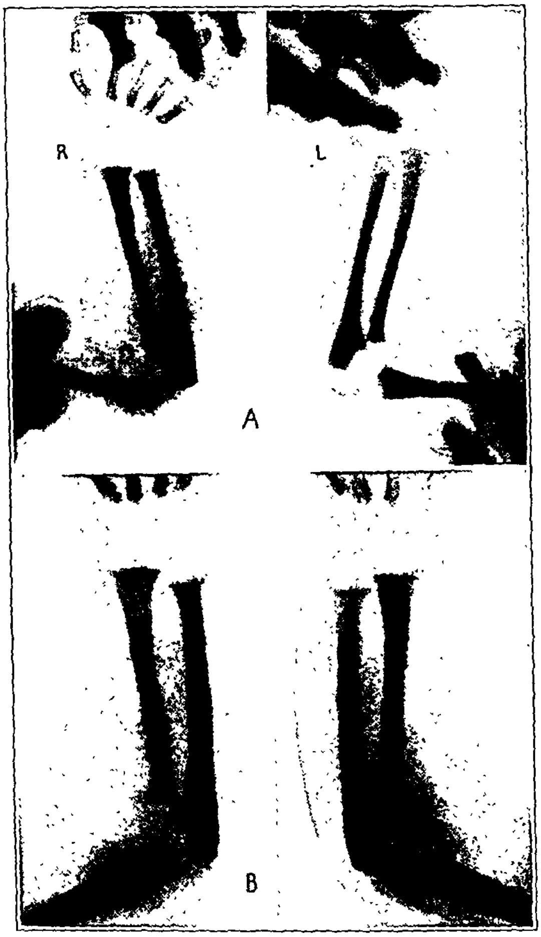

Fig. 1.—*A*, cupping of ulnas of baby 2 shortly after birth; *B*, characteristic rachitic changes of radius and ulna in same infant at 13 weeks of age.

---

From the x-ray and obstetric departments of the Jefferson Hospital.

[3] Schmorl, G.: Die pathologische Anatomie der rachitischen Knochenerkrankung, Ergeb. d. inn. Med. u. Kinderh. **4**: 403, 1909.

of rickets. Hess[4] cites the earlier histologic work of Pommer[5] in which the observations were identical with those of Schmorl.

Alterations in the diaphyso-epiphyseal line due to rickets are reflected in roentgenograms. The characteristic saucer-shaped deformity and jagged irregularity of the end of the diaphyses are universally recognized.

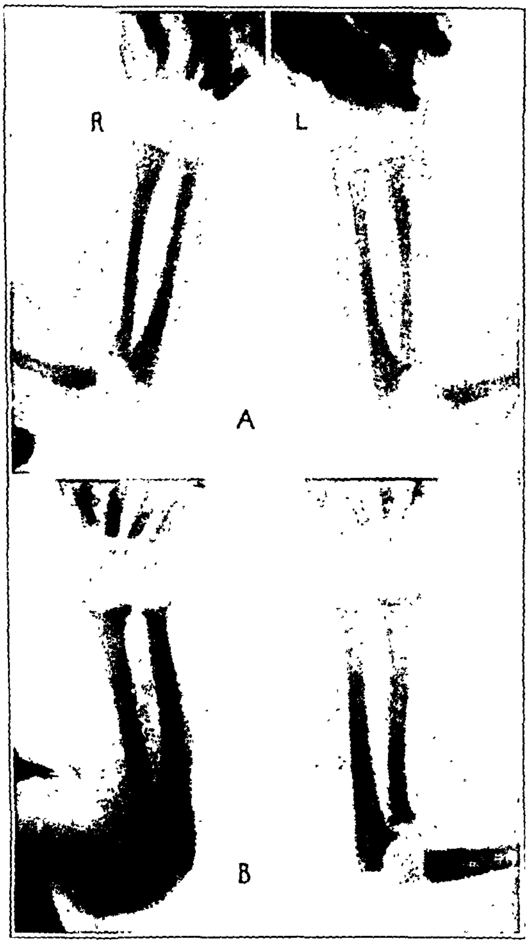

Fig. 2.—*A*, cupping of ulnas of baby 5, shortly after birth; *B*, characteristic rachitic changes of radius and ulna in same infant at 13 weeks of age.

In an attempt to find patients suitable for use as controls in a study of antirachitic agents, we made roentgenograms of the long bones of forty-two infants ranging in age from 3 to 28 weeks. Two infants, aged 4 weeks, and two, aged 5 weeks, showed cupping. We thought that this deformity might be rachitic.

To determine the earliest age at which cupping could be found roentgenographically we roentgenographed a group of Negro infants born during the months of February, March and April. We chose Negro infants because of the high incidence of clinical rickets in children of this race. Theoretically, the material was eminently suitable for the development of congenital rickets; the majority of the mothers came from unhygienic homes, lived on diets poor in vitamin D and received very little sunshine during the latter months of pregnancy.

The forty-eight new-born Negro infants in this selected group were roentgenographed within the first two days of life. Seven showed evidence of abnormality, cupping or flange formation in one or more of the bones. Cupping of the ulnas was present in each of the seven; in two the fibulas were also involved, and in one instance the ends of each radius, ulna, tibia and fibula were altered, as shown in the accompanying table. Five of the seven we were able to reexamine after an interval of several weeks. Two, studied thirteen weeks after birth, showed marked cupping and irregularity of all the bones (figs. 1 and 2). One infant showed cupping of the ulnas alone at 8 weeks; another, at 5 weeks of age, showed changes in the fibulas in addition to those noted in the ulnas at birth. One infant, reexamined at 3 weeks of age, was normal.

Of the two infants showing cupping at birth who were not reexamined, one died and autopsy was not obtained, and the mother of the other refused to have her baby restudied.

*Results of Roentgen Examination at Birth and a Subsequent Examination at a Later Date**

| | First Examination | | | | Second Examination | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Baby | Ulna | Fibula | Radius | Tibia | Ulna | Fibula | Radius | Tibia | Age at Second Examination | Maternal Prenatal Environment | Cord Wassermann Reaction | Maternal Wassermann Reaction |
| 1 | | .. | .. | .. | + | + | .. | .. | 5 wks. | Very poor | Neg. | Neg. |
| 2 | + | .. | .. | .. | + | + | + | + | 13 wks. | Very poor | Neg. | Neg. |
| 3 | | .. | .. | .. | + | .. | .. | .. | 8 wks. | Poor | Neg. | ..... |
| 4 | | .. | .. | .. | Not repeated | | | | | Poor | Neg. | Neg. |
| 5 | | .. | .. | .. | | | | | 13 wks. | Fair | Neg. | Neg. |
| 6 | | .. | .. | .. | 0 | 0 | 0 | 0 | 3 wks. | Good | Neg. | Neg. |
| 7 | | + | + | + | Died | | | | | Poor | Anti-Comp. | Neg. |

* The presence of cupping is indicated by a plus sign.

These studies clearly indicated the existence of cupping in the new-born. From the clinical course, with the development at a later date of the unmistakable rachitic deformity, it appeared that the cupping was probably due to congenital rickets. In an attempt to confirm these observations, we next studied roentgenographically and by histologic sections the ends of the long bones of still-born infants. Cupping was again

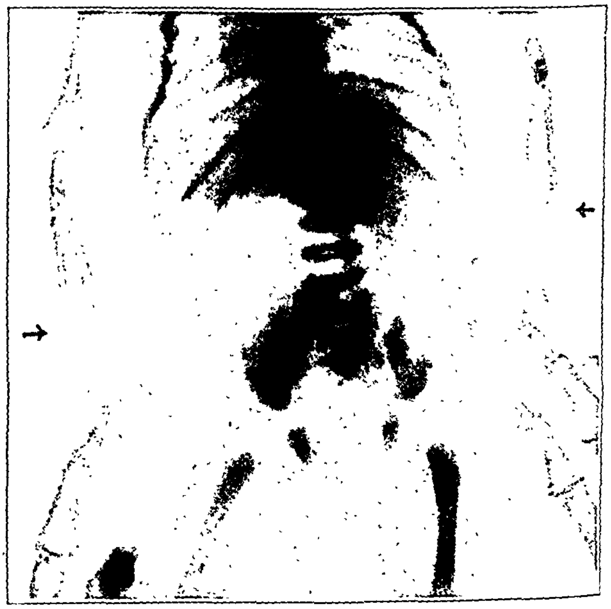

Fig. 3.—Ulnas of still-born normal infant; cupping indicated by arrows (microscopic section shown in figure 4).

---

4. Hess, A. F.: Rickets Including Osteomalacia and Tetany, Philadelphia, Lea & Febiger, 1929.

5. Pommer, G.: Untersuchungen über Osteomalacie und Rachitis, Leipzig, F. C. W. Vogel, 1885 (quoted by Hess, footnote 4).

observed roentgenographically (fig. 3); but, on microscopic study of sections of the ends of the bones, none of the evidences of rickets were found. Instead of an irregular line at the diaphyso-epiphyseal junction made up of numerous prolongations of cells sent out by the cartilaginous overgrowth, as is characteristic of rickets, a perfectly regular and normal arrangement of columns was found. However, the zone of preparatory calcification, instead of joining the zone of proliferating cartilage as a straight or convex line as is usual in normal bone, presented a concave surface (fig. 4). This concavity was responsible for the cupping noted roentgenographically.

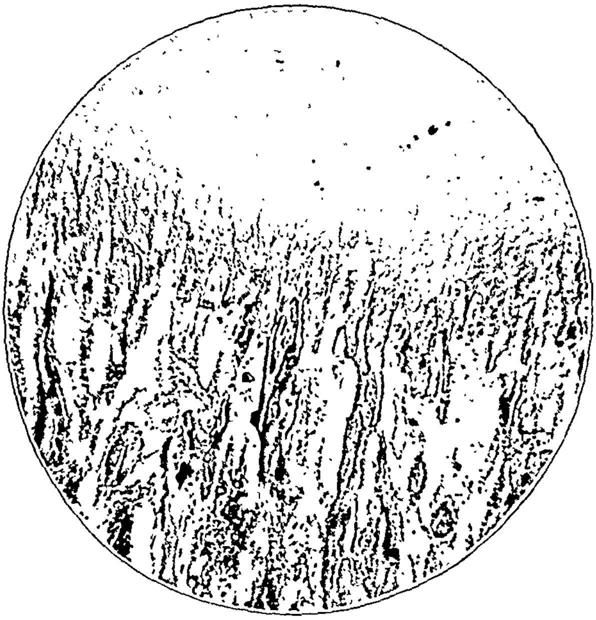

Fig. 4.—Section of ulna of still-born baby (fig. 3) showing a concavity in which the zone of preparatory calcification joins the zone of proliferating cartilage. This concavity is seen as cupping roentgenographically in figure 3.

### SUMMARY

1. In a series of forty-eight new-born Negro infants, cupping of the long bones was found in seven; of these, unmistakable evidence of clinical rickets appeared in four from five to thirteen weeks after birth.
2. A similar deformity was found roentgenographically in still-born infants, but on histologic examination there was no microscopic evidence of rickets.
3. The cupping was due to a concave variation from the usual normal straight or convex line at the junction of the zone of proliferating cartilage and the zone of preparatory calcification.

### CONCLUSION

Roentgenographically recognizable cupping is sometimes present normally in the ends of the long bones of new-born infants, caused by a normal variation in the manner in which the zone of preparatory calcification joins the zone of proliferating cartilage.

# Clinical Notes, Suggestions and New Instruments

## A HOLLOW KIDNEY STONE

Howard L. Cecil, M.D., Baltimore

Stones that have remained in the ureter for a long time occasionally have holes through them. I have such a specimen, which was removed from a man who gave a history of ureteral colic for several years. Other urologists have found similar specimens. The method of formation of these stones is similar to that of other calculi. The deposit is made on the primary calculus, but it follows the circumference of the ureter, leaving a groove or a hole through the stone.

The specimen presented here is so unusual and the conditions contributing to its formation so rare that it seems wise to report it. I have not found the report of a similar case. Joly says it is impossible for hollow stones to form. He did not, however, consider such unusual conditions as those contributing to the formation of this stone.

*History.*—A man, aged 31, complained of a pain in each kidney, worse on the left side. The patient's father had tuberculosis; the patient had been associated with him during eight months of his illness.

The patient stated that he had had an injury to the spine three years before. No defects could be found. His previous history was otherwise negative except for the following:

When the patient was 3 years old, he was kicked by a horse on the right side. The three lower ribs were fractured and there was evidently an injury to the right kidney. He had hematuria for about three days but recovered completely in about three weeks. During the following sixteen years there was no trouble. While in the navy, he fell from a hammock and again injured the right side. He again had hematuria, which recurred at intervals during the following eight years. There were numerous attacks of severe pain in the right side, accompanied by nausea and vomiting, but no chills or fever. During all these eight years, there was a thin, watery, urethral discharge. This was diagnosed as gonorrhea and treated as such while he was in the navy. He stated that no exposure occurred which could have accounted for gonorrhea.

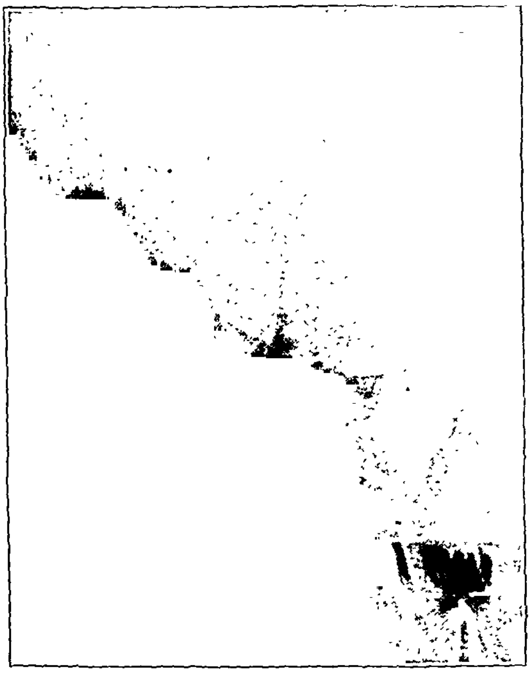

Fig. 1.—Appearance of stone in plain roentgenogram.

Eight years after the injury in the navy he consulted a surgeon, who made a roentgen examination and found a stone in the right kidney. A cystoscopic examination was not done. The stone was removed through a pyelotomy. After the operation the surgeon told the patient that he was sorry he had not removed the kidney.

*Following the operation, there was no urethral discharge and* no hematuria, but the patient had almost constant pain in the right kidney region. One year after the removal of the stone, pain began in the left kidney region. This had gradually grown worse until, on admission, it was very severe and worse than that in the right side. The pain in the left side was located in the back beneath the last rib. It did not radiate. The pain in the right side radiated to the rectum, bladder and testicle. He again noticed hematuria three days before; there had been none for twenty-four hours.

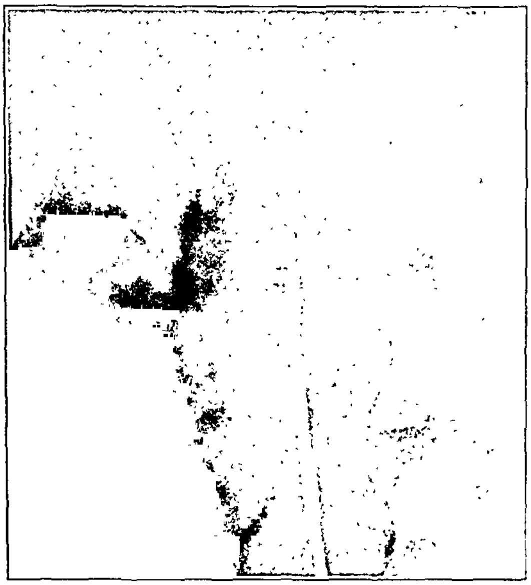

Fig. 2.—Pyelogram of kidney four years after removal of stone.

*Examination.*—General physical examination was negative. There was no tenderness over either kidney region; neither kidney could be felt.

The sphincter tone was good. The rectum was normal. The prostate was larger than normal. It was indurated throughout, particularly on the outer borders. The seminal vesicles could not be palpated, except the lower portion, but appeared thickened. The secretion contained considerable pus.

Examination of the urine was negative for albumin, sugar, pus, blood, casts and infection (smear).

A phenolsulphonphthalein test resulted in the return of 60 per cent of the dye in the first half hour, and 10 per cent in the second half hour.

A cystoscope entered with ease. The prostatic orifice and bladder were normal. A number 8 catheter was passed with ease up the left ureter. A number 6 passed with difficulty up the right.

Nothing was obtained from the right kidney. Examination of the left kidney was negative for pus and infection. Phenolsulphonphthalein appeared in three minutes; 40 per cent was collected in fifteen minutes.

Roentgenograms made before the removal of the stone showed a shadow 3 by 2 cm. opposite the second lumbar vertebra (fig. 1) just between the twelfth rib and the psoas muscle. The shadow was faint, with the greatest density at the periphery. The outline of the kidney was not shown.

Pyelograms done four years after the removal of the stone (fig. 2) showed ureters of normal size and position. The pelvis of the right kidney was circular and measured 1 cm. The calices were represented by two small projections 0.5 cm. in diameter and length. A pyelogram of the left kidney was negative.

Following this examination, the temperature rose to 105 F. and remained high during the following two days. There was considerable nausea and vomiting. The urinary output was scant. There was considerable pain, most marked in the left kidney region. The urine, which had been free of pus, now contained a great deal, as well as many bacilli. For fear that the left and only functioning kidney might be infected, another cystoscopic examination was done. Apparently clear urine was coming from the left kidney, but a thick, creamy pus exuded from the right ureteral meatus. Since the temperature was accounted for by the infection of the right kidney, ureteral catheterization was not done, as it seemed impossible to drain the kidney adequately by this method. The patient quickly recovered from this flare up but refused operation at this time. He returned one month later and the right kidney was removed.

*Operation and Result.*—The scar was excised and the usual approach to the kidney easily carried out. In spite of a careful search, the kidney was not found. The ureter was identified and was followed upward into a mass of scar tissue about 4 cm. long and 3 cm. thick. This was removed and represented the remains of the kidney.

The recovery was uneventful. The patient was discharged from the hospital ten days after the operation. The infection of the urine quickly cleared up after the operation.

*Pathologic Examination.*—This was done by Dr. Gofarth. The specimen was an irregular structure, measuring 3 by 2 by 2 cm. Tags of fatty tissue were attached. A duct extended from the mass for about 3 cm. On section, it was found that the central part of the specimen had undergone cystic change. Cloudy mucoid fluid was present.

Microscopically, section through the specimen showed chiefly scar tissue. Here and there, remnants of tubules and occasionally an obliterated or obliterating glomerulus was seen. In the center of the specimen, cystic structure lined by pelvic mucosa was demonstrable. Section through the ureter showed the entire wall heavily infiltrated with chronic inflammatory cells.

The diagnosis was total destruction of the kidney secondary to infection.

The stone removed at the previous operation was light yellow and measured 3.5 by 3 by 2 cm. (fig. 3). It was a mere shell. Its weight was 1.8 Gm. There were three holes in it, two at the upper end and one at the lower end. The outer surface was slightly irregular but smooth. There was no evidence that stone had been formed by deposits on the pelvic wall. The inner surface was very smooth. The wall was thin, varying from about 0.1 to 0.5 mm.

Analysis of the stone showed that it consisted chiefly of phosphates, but it had some organic material in it. There were no oxalates or uric acid.

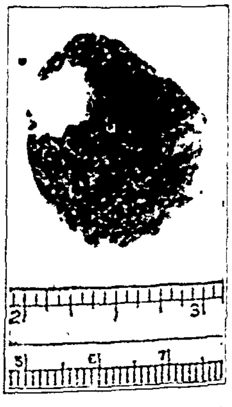

Fig. 3.—Stone removed at previous operation.

COMMENT

Most probably, the severe injury to the kidney when the patient was 3 years old caused a blood clot to fill the pelvis of the kidney. Urinary salts were deposited on the clot, which disintegrated, leaving a thin shell. At about this time the kidney ceased functioning; otherwise the center of the stone would have been filled with salts, and the stone would have grown up into the calices. It is known that in some cases of severe trauma the kidney secretes for a short time and then ceases to function. It is to be assumed that this is what happened in this case.

The injury he suffered sixteen years later does not seem to have been sufficient to destroy the kidney but was probably sufficient to cause trouble in one already filled with a stone and probably severely infected. All subsequent symptoms can readily be accounted for by the infection in a destroyed kidney.

The case demonstrates again the advisability of late examination of patients who have had severe kidney injuries.

## A PUMP FOR CLINICAL AND LABORATORY PURPOSES WHICH EMPLOYS THE MILKING PRINCIPLE

C. M. Van Allen, M.D., Peiping, China

The instrument here presented pumps fluid or gas through a rubber tube by the action of a series of rollers on a tube. It has been in use for several years and has proved advantageous for numerous clinical and laboratory operations, including direct and indirect blood transfusion, aspiration of fluids from body cavities, infusion, administration of artificial pneumothorax, and circulation between appliances for various purposes. The transfusion of blood and the administration of pneumothorax are the more recent accomplishments and are done with particular facility. The milking principle of the pump deals well with viscid, sticky or coagulable fluids while pumps that depend on the action of pistons or automatic valves are liable to obstruction. Additional features are the continuous stream, accurately measurable delivery, instantly reversible action, production of ample degrees of both pressure and suction, and ready adaptability to aseptic operation.

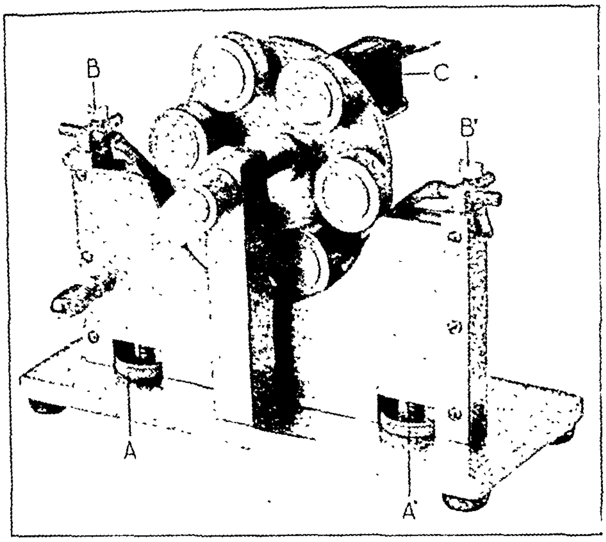

Fig. 1.—The pump.

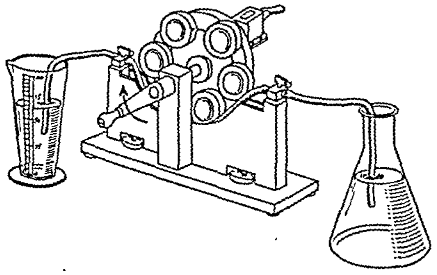

Fig. 2.—Method for calibrating the pump. The number of revolutions required to displace 100 cc. of water into the graduated container is determined and the displacement at each revolution is calculated. These values serve thereafter for estimating displacements while pumping either liquids or gases.

The pump has a wheel 14 cm. in diameter, mounted vertically with shaft and bearings on a base (fig. 1).[1] A driving handle is attached to the shaft. Six rollers are mounted on bearings at regular intervals along the periphery of the wheel, and they are met and pressed against from below by a semicircular track 30 cm. long. The track is supported on springs, the tension of which is adjustable by two thumb-screws (*A, A'*). Between the rollers and the track lies a rubber tube, which is held in place by connection to two short metal tubes fixed at the ends of the track. Each metal tube is T shaped and has two free limbs for the attachment of outside lead-tubes. One of the free limbs carries a stopcock (*B, B'*). An automatic counter (*C*) on the shaft records the revolutions of the wheel. Construction is metallic and durable throughout, except for the tube under the rollers, which is made of live rubber and is replaceable from stocks of standard hospital tubing. The tube suitable for most purposes has an internal diameter of about 6 mm., but larger ones, up to 1 cm. in caliber, can be used. The tubes in the pump, together with any lead-tubes that may be attached, are removable without separation from one another.

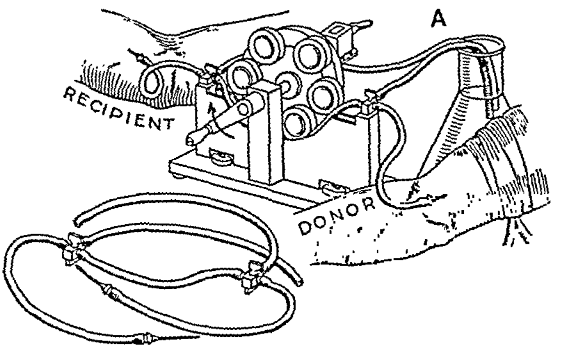

Fig. 3.—Method for direct blood transfusion. Tubes at *A* lead to a flask of saline solution. All tubes are filled with saline solution beforehand and are flushed with it at any time that transfusion is temporarily stopped. This is done by opening the stopcocks of the tubes to the saline solution, one at a time, and by pumping in the appropriate directions. The cocks are kept closed, as shown, at other times. Inset shows the tubes and needles assembled and removed from the pump preparatory to sterilization for whole blood transfusion.

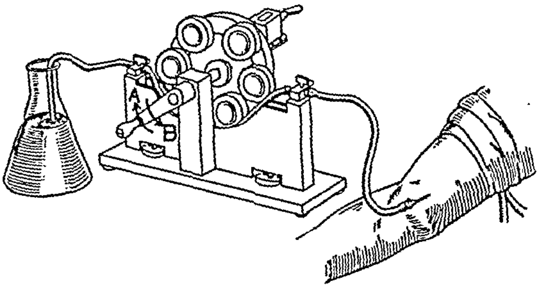

Fig. 4.—Method of drawing blood into citrate solution (direction of rotation *A*) and of injecting citrated blood (direction *B*) for indirect blood transfusion. Aspiration and injection of fluids in other parts of the body are performed similarly.

Pumping is accomplished by turning the wheel; the rollers drive the contents of the tube ahead and the elastic recoil of the tube draws in more contents from behind. When resistance at the ends of the tube interferes with these effects, pressure is produced ahead and suction behind, either of which may be as great as the rubber can carry without bursting from its connections or collapsing. The tension of the springs must be sufficient to obliterate completely the lumen of the tube but not great enough to cause the rollers to push the tube forward. While the total volume pumped must be calculated from the number of revolutions, the volume per revolution should be determined by trial beforehand, by pumping water into a graduated container (fig. 2). A 6 mm. tube delivers about

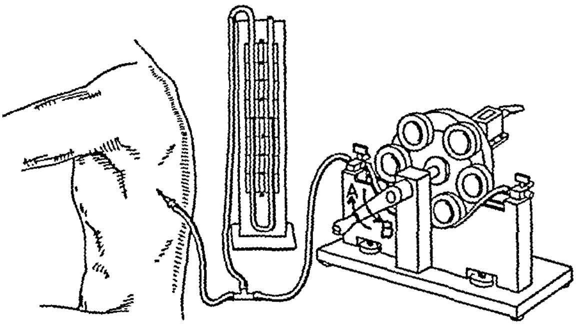

Fig. 5.—Method for administering (direction *A*) or eliminating (direction *B*) pneumothorax. It is only necessary to stop pumping at any time to obtain the intrathoracic pressure from the manometer.

---

From the Department of Surgery, Peiping Union Medical College.

[1] A few pumps may be obtained from the Peiping Union Medical College, Precision Shop.

10 cc. at each revolution. The figure for water applies also for more viscid fluids and for gases. The error in such calculations should not exceed 0.5 per cent; but care must be taken that the rate of pumping does not exceed the rate of supply, which event is indicated at once by the collapse of the tube on the intake side. For aseptic operation, all tubes to be used are first assembled, then detached from the pump without separation from one another (fig. 3, inset), sterilized by boiling and reinserted at the time of operation. Reinsertion can be done without contaminating the outsides of the free ends of the lead-tubes, or the interior of any part of the system of tubes. Before an operation is begun the entire system may easily be pumped full of fluid and all the air eliminated, if this is desired.

Some clinical uses and methods are illustrated in figures 3, 4 and 5. Complete details for performing artificial pneumothorax and whole blood transfusion are to be reported in separate publications.

Originality is not claimed for the use of the milking principle, since pumps of other designs have employed it before, as for instance that designed by DuNuöy. However, the pump described here is the only one known to me which has sufficient precision and adaptability for general medical purposes.

---

# CORONARY THROMBOSIS WITHOUT PAIN: ITS INCIDENCE AND PATHOLOGY

Nathan Smith Davis III, M.D., Chicago
Assistant Professor of Medicine, Northwestern University Medical School

There is a syndrome that is not associated with angina which may follow coronary thrombosis more frequently than has generally been reported. It is characterized by the abrupt onset of dyspnea, which may be paroxysmal or continuous and is unprovoked by exertion; and by shock, lowered blood pressure, disordered or weakened heart action, fever, leukocytosis, pericardial friction or embolic complications. Death may ensue in a few hours or days from ventricular fibrillation or rupture. There may be a partial recovery, after a long convalescence, which, usually in less than two years, is followed by an intractable congestive heart failure and death. Aubertin and Lereboullet[1] have reported a series of cases of coronary thrombosis in which this syndrome was present in about 20 per cent, and the anginal syndrome in about 80.

In a review of the records of patients at the Alexian Brothers' Hospital, Chicago, in whom a diagnosis of coronary thrombosis could be made, basing it on history, physical and laboratory observations and electrocardiograms, twenty patients were found who had had precordial pain or distress and sixteen who complained of dyspnea, abrupt in onset and unprovoked by effort, but did not complain of pain (table 1).

A study was also made of the records of the Department of Pathology of Northwestern University Medical School from Jan. 1, 1925, to June 30, 1931, to determine the relative incidence of the syndrome without history of pain. In this series of fifty-three cases, including the thirteen from the Alexian Brothers' Hospital in which the diagnosis was confirmed by necropsy, twenty-one were found in which there was coronary thrombosis with a history of pain, twenty-one in which there was no history of pain, and eleven cases of sudden death in which there was no history at all (table 2). The two series of cases are combined in table 3.

How is the absence of pain or precordial distress to be accounted for? Herrick[2] states in his Harvey Lecture: "It has been suggested that normally certain areas of the heart are not only less vital than others, indifferent or silent they have been called, but also less sensitive. At autopsy fresh infarcts are sometimes found associated with multiple areas of fibrosis that speak for previous obstruction of small branches, yet no pain has been noted, *no pain even announcing the recent infarction.* There has evidently been a very gradual and progressive narrowing of the artery by sclerotic processes. The area irrigated by the artery has become relatively inactive, relatively anesthetized by destruction of vessels, nerves and functioning muscles, so that a painful response to the new obstruction is lacking. The final complete obstruction comes without a sudden shock, the element of surprise is lacking as the heart is in a sense prepared for the supreme insult. Abrupt heart failure with its dyspnea and other phenomena may be present, but pain may be lacking. These are the 'substitution symptoms' in the hyposensitive described by Libman. As Obratzow and Straschesko expressed it, dyspnea may be the pain equivalent."

It is generally believed that the pain both of the angina of effort and of coronary thrombosis is due to a relative ischemia of the heart muscle; that it is similar in origin to the pain arising in skeletal muscle in which there is a relative ischemia whether produced by pathologic processes or by artificial means.[3] From a study of the pathologic records in the series reported, it appears that in the cases not associated with pain the coronary thrombosis caused not an area of relative ischemia, but one of absolute ischemia, with complete necrosis of tissue, an anemic infarct as pointed out by Sutton.[4] When the patient survives for some weeks or months, a cardiac aneurysm often forms at the site of the infarction. In some instances the conditions were similar to those described by Herrick in the passage cited; in others the infarct was not associated with multiple areas of fibrosis but was apparently due to obstruction of an end artery.

Table 1.—*Incidence of Coronary Thrombosis Without Pain in the Series of Cases Diagnosed as Coronary Thrombosis at Alexian Brothers' Hospital, Chicago*

| | Number | Per Cent | Confirmed by Necropsy |
|---|---|---|---|
| Coronary thrombosis with history of pain... | 20 | 56 | 8 |
| Coronary thrombosis without history of pain. | 16 | 44 | 5 |
| | 36 | 100 | 13 |

Table 2.—*Incidence of Coronary Thrombosis Without Pain in the Series of Cases of Coronary Thrombosis from the Department of Pathology, Northwestern University Medical School*

| | Number | Per Cent |
|---|---|---|
| Coronary thrombosis with history of pain......... | 21 | 40 |
| Coronary thrombosis without history of pain....... | 21 | 40 |
| Coronary thrombosis without history (sudden deaths) ........................................ | 11 | 20 |
| | 53 | 100 |

Table 3.—*Incidence of Coronary Thrombosis Without Pain in in the Series of Cases from Alexian Brothers' Hospital and the Department of Pathology, Northwestern University Medical School* *

| | Number | Per Cent |
|---|---|---|
| Coronary thrombosis with history of pain........ | 36 | 47 |
| Coronary thrombosis without history of pain...... | 29 | 38 |
| Coronary thrombosis without history ............. | 11 | 15 |
| | 76 | 100 |

* The thirteen cases from Alexian Brothers' Hospital in which the diagnosis was confirmed by necropsy also appear in the series from the Department of Pathology, Northwestern University Medical School.

It appears from this study of hospital and pathologic records that coronary thrombosis with a syndrome characterized by the abrupt onset of dyspnea and heart failure, unprovoked by effort, may be more common than is generally believed; that this syndrome may be due to the formation of an area of absolute ischemia, an anemic infarct, whereas the syndrome characterized by "severe, enduring, substernal or epigastric pain, unprovoked by effect,"[2] is due to the formation of an area of relative ischemia.

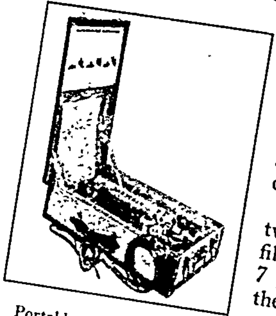
## Council on Physical Therapy

The Council on Physical Therapy of the American Medical Association has authorized publication of the following report.
H. A. Carter, Secretary.

### THE H-H INHALATOR ACCEPTABLE

The H-H Inhalator, manufactured by the Mine Safety Appliances Company, Pittsburgh, is used, according to the firm, for the "successful resuscitation of victims of carbon monoxide poisoning, gas asphyxia, electric shock, drowning, and asphyxia in the new-born," and as "an adjunct to prone pressure method of artificial respiration."

There are two types of H-H Inhalator on the market; namely, the portable type and the hospital type.



Portable Type H-H Inhalator.

The portable type is equipped with two 16 cubic foot cylinders of Carbogen, a proprietary product consisting of carbon dioxide 7 per cent and oxygen 93 per cent, complete with breathing bag, facepiece, tubes, gages and valves. The shipping weight complete is 72 pounds.

The hospital type is equipped with two 200 cubic foot cylinders, one filled with Carbogen (carbon dioxide 7 per cent, oxygen 93 per cent) and the other with chemically pure oxygen, mounted with a panel board on a substantial hospital cart, so that it may be easily moved about the emergency room, operating room or to other locations in the hospital. Its shipping weight complete is 515 pounds.

#### DIRECTIONS

How to use the device:

1. Open cylinder valve and valve between cylinder and pressure gage.
2. Open low pressure regulating valve one complete turn until breathing bag is inflated, then turn pointer back to 10 on the dial.
3. Inflate cushion and place the mask over the nose and mouth of the patient.
4. Watch breathing bag for indications of patient's respiration.
5. When the patient's breathing increases, open the low pressure regulating valve to increase the flow of the Carbogen (carbon dioxide 7 per cent, oxygen 93 per cent) so as to keep the breathing bag from collapsing each time the patient inhales.
6. Apply inhalator until patient is breathing freely and entirely conscious.

#### DESCRIPTION OF PRONE PRESSURE METHOD

In using the prone pressure method, place the person on his abdomen, and remove from his mouth all foreign bodies, such as false teeth, tobacco and gum; the tongue usually falls forward of its own weight, but see that it is forward. Turn his head to one side and rest it on his forearm, so that the mouth and nose will not come in contact with the ground, and extend the other arm forward.

Kneel and straddle the victim's thighs, facing his head. The palms of your hands are placed on the small of the back with the fingers over the ribs, the little finger just touching the lowest rib, the thumb alongside the fingers, the tips of the fingers just out of sight. With arms held straight, swing forward slowly so that the weight of your body is gradually brought to bear on the person. This operation, which should take about two seconds, must not be violent lest the internal organs be injured. The lower part of the chest and also the abdomen are thus compressed and air is forced out of the lungs. Now immediately swing back slowly to remove the pressure, thus returning to the original position. Through their elasticity, the patient's chest walls expand and his lungs are thus supplied with fresh air.

After two seconds, swing forward again and repeat deliberately about fifteen times a minute the double movement of compressing and releasing, thus causing a complete respiration in about four seconds. Continue artificial respiration until natural breathing has been restored or a physician has arrived.

#### COMMENT

The H-H Inhalator is simple in design and practical in operation. Two cylinders of Carbogen (carbon dioxide 7 per cent, oxygen 93 per cent) should provide a continuous supply for long periods. Spare cylinders can be inserted without interrupting operation. Special valves are used for the simple manual control of the gas from the cylinders to the reducing valve. The pressure gage registers in atmospheres the supply of prepared oxygen available for use from either cylinder. The McCaa Type reducing valve regulates the flow of gas at low pressure, which does not exceed 5 pounds per square inch. The low pressure regulating valve graduated in liters per minute controls the flow of the gas to the patient. A safety or relief valve protects the patient from injury due to high pressure in the breathing bag. The rubberized fabric breathing bag permits the operator to observe each respiration of the patient. Wire reinforced hose assures free flow of the gas from the breathing bag to the patient. As a part of the facepiece, the check valve chamber eliminates any dead air space and provides the patient with a supply of fresh air and permits the easy elimination of each exhalation. The facepiece is transparent and permits observation of the condition of the mouth and nose of the patient. The facepiece is provided with a pneumatic rubber cushion which assures a perfect fit. Tongue forceps and an oral screw are mounted in the lid ready for use.

The name of the inhalator is derived from the fact that it was developed by Dr. Yandell Henderson and Dr. Howard W. Haggard of Yale University. The initials (H-H) of the names are used.

The Council on Physical Therapy accepts the H-H Inhalator for inclusion in its list of devices for physical therapy.

---

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.
W. A. Puckner, Secretary.

**COD LIVER OIL** (See New and Nonofficial Remedies, 1931, p. 259).

**Scott's Norwegian Cod-Liver Oil (Plain).**—It has a vitamin A potency of not less than 1,000 units per gram as determined by the method of the U. S. Pharmacopeia and a vitamin D potency of not less than 250 units per gram when tested by the method of the American Drug Manufacturers Association.

*Dosage.*—For patients over 5 months of age 4 cc. (1 fluidrachm) three times daily.

Manufactured by Scott & Bowne Laboratories, Bloomfield, N. J. No U. S. patent. U. S. trademark 17960.

*Scott's Norwegian Cod-Liver Oil (Flavored).*—Scott's Norwegian cod-liver oil (plain), containing 0.78 per cent of a mixture of oils of peppermint, sweet birch, cassia and bitter almond as flavoring.

*Scott's Emulsion of Cod-Liver Oil.*—It has a vitamin A potency of not less than 140 units per gram as determined by the method of the U. S. Pharmacopeia and a vitamin D potency of not less than 70 units per gram when tested according to the method of the American Drug Manufacturers Association (*J. Am. Pharmaceutical A.* **20:** 588 [June] 1931). Scott's emulsion of cod liver oil is prepared from Scott's Norwegian cod-liver oil (plain) 27.9 per cent (30 per cent by volume); glycerin 12.5 per cent, acacia 1.56 per cent, tragacanth 1.46 per cent, flavoring 0.15 per cent, agar 0.03 per cent, and water to make 100 per cent.

*Dosage.*—For adults 15 cc. (4 fluidrachms) three or four times daily; for children 15 cc. (4 fluidrachms) twice daily.

Scott's Norwegian cod-liver oil (plain) complies with the U. S. P. standards for cod liver oil. In addition, it is required to have a content of fat-soluble vitamin A, determined by the U. S. P. method, of not less than 1,000 units per gram, and an antirachitic potency, determined by the method of the American Drug Manufacturers Association (*J. Am. Pharmaceutical A.* **20:** 588 [June] 1931) of not less than 250 units per gram.

# REPORTS OF THE COUNCIL

The Council has authorized publication of the following reports.

W. A. Puckner, Secretary.

## "ANTI-CEPT" NOT ACCEPTABLE FOR N. N. R.

"Anti-Cept," according to the Anti-Cept Company, Los Angeles, is a "Vaginal Antiseptic Powder, Safe—Pleasant—Effective" which is applied in the form of a powder by means of a powder blower.

No statement of the composition of "Anti-Cept" appears on the label of the package. In an advertising circular, the following statement of composition is given: "Chloral Hydrate 10%, Silver-Nitrate Powder 2%, Menthol 1%, Boric acid 55%, Alum 5%, Quinine Sulph. 2%, Kaolin 25%." The formula furnished the Council by the Anti-Cept Company differs from the formula just quoted in that the amount of boric acid is given as 56% and the amount of quinine sulphate as 1%.

No evidence for the rationality of this complex mixture or of its effectiveness was furnished the Council. The silver nitrate component of the mixture becomes incompatible with the other ingredients, especially the chloral, at least when water is added. The following questionable statement in reference to the chloral hydrate contained in the mixture was made to the Council: "This is used as a depressor action on the secretory nerve fibers, supplying the glands of the cervix. It also has a sedative action on the individual. It is a known fact that the vaginal discharge is most prevalent in the nervous type of individual." Although the preparation is not claimed to contain volatile oils, and menthol is the only declared constituent related to essential oils, the claim is made in the information sent the Council that "It is a deodorant composed of various oils which are soothing and have a pleasant effect on the individual. . . ."

The following misleading and essentially false statement is made in the advertising circular: "Anti-Cept is highly recommended by the medical profession as a vaginal antiseptic. Its value has been proven. It replaces the antiquated methods of treating ulcerations, erosions and infections of specific and nonspecific origin of the cervix."

Anti-Cept is ineligible for admission to New and Nonofficial Remedies because it is an unscientific complex mixture of indefinite composition, which is marketed under a noninforming, therapeutically suggestive name and with unwarranted claims.

## EUBETIN NOT ACCEPTABLE FOR N. N. R.

Eubetin "for Diabetes" is a product of Eubetin G.m.b.H., Hamburg, Germany, Aesculap Pharmaceutical and Chemical Co., Inc., New York (G. W. Steiger Co.), acting as U. S. distributor.

Eubetin, according to the information furnished the Council, has the following percentage composition: "Natr. bic. 67%; Magn. carb. 6.70%; Kal. bicarb. 13.40%; Calc. Phosph. 5.40%; Natr. sulf. 2.95%; Kal. sulf. 0.82%; Natr. chlor. 1.20%; Extract. bact. (bac. Chauvoei); carb. lign. subt. adsorb. 2.53%." While the same statement of composition appears on the submitted packages, the advertising circular enclosed with the packages declares: "It is impossible to keep the ratio between the various compounds of every series of manufacture the same. Every time the bacteriologic extract is newly prepared, the ratio must be compounded afresh, according to the results of the animal experiments. Thus an even efficacy of the total compounds is guaranteed." However, neither the advertising nor the information furnished the Council contains any statement in regard to the method by which it is claimed that the potency and uniformity of the preparation is controlled, nor is there even an informative statement in regard to the composition of the "bacteriological extract."

The following statement in reference to the composition of Eubetin is offered in the advertising: "EUBETIN consists mainly of two groups of ingredients. The first is inorganic. It is so compounded that it specially prepares the way for action of the organic group. The latter consists of substances which Collip has called 'Glukokinines.' They resemble in their function the animal insulin, being, however, produced from the tissues of lower animals and plants. The 'Glukokinines' contained in EUBETIN are of bacteriological extraction, and are obtained from certain branches of the bacillus chauvoei." About eight years ago, considerable attention was given to an insulin-like substance which appeared to be contained in a variety of plants, bacteria, and even animal tissue. To this substance or group of substances the name "glucokinin" was applied. At that time efforts were being made to utilize these glucokinines as substitutes for insulin. In this country considerable attention was given to a blueberry leaf extract, and in 1927 the Council issued a report on the experimental status of this preparation. Although much experimentation was done with this preparation, its manufacturer has not placed it on the market.

In the advertising which accompanies the Eubetin package, it is stated that "EUBETIN may be used in all forms of Diabetes . . . ," and it is claimed that the effect is "permanent." The drug is to be taken by mouth, it being claimed that the destruction of the "bacteriological extract" is prevented by its being "embedded in charcoal," so that it is "not absorbed by the stomach but by the bowels." No evidence for the effectiveness of Eubetin as a substitute for insulin is offered in the advertising, nor was such evidence submitted to the Council. The name "Eubetin" (good for diabetes) is not only not informative of the composition of the product but is therapeutically suggestive.

The Council declared Eubetin unacceptable for New and Nonofficial Remedies because its composition is indefinite, because no evidence is offered that it possesses therapeutic value or that its potency is demonstrated or controlled; because it is sold under a therapeutically suggestive name which is noninformative of the composition of the product, with unwarranted claims in such a way as to lead the public to place false dependence on it in a disease the management of which requires the supervision of a physician.

## DE-GERM NOT ACCEPTABLE FOR N. N. R.

De-Germ contains, according to the label, "Essential Oils" (the identity of which is not declared) 4 per cent, "Sodium and Potassium Oleates (Soaps)" 2.5 per cent and solution of formaldehyde U. S. P. 10 per cent. Since the pharmacopeial formaldehyde solution is required to contain not less than 37 per cent of formaldehyde, it appears that De-Germ is a soap solution containing about 3.7 per cent of formaldehyde admixed with essential oils. According to the Dale Products Co., which requested consideration of the product, De-Germ is "the Perfect Purifier" and is a disinfectant, deodorant and germicide which "Helps Prevent all Contagious Diseases." The invitation to "Try a Few Drops in the Bath, the Washing Machine and the Dishpan or on your Handkerchief," which appears on the label, may lead the purchaser to place false dependence on the product. It is claimed that De-Germ is an "especially efficient Disinfectant and Germicide" which is to be used freely "to combat the spread of contagious diseases, such as colds, influenza, scarlet fever, diphtheria, etc." As evidence of the efficacy of De-Germ, a report is quoted from what is designated to be a "Nationally Known Laboratory," in which it is stated that, while germs were found on culture plates exposed in a room that could be tightly closed, there was no development of germs on such plates when they were exposed in the same room after the walls, floors and ceiling had been sprayed with De-Germ according to directions. It is well known that when used properly, formaldehyde is a most efficient disinfectant. When a formaldehyde preparation is sprayed in a room that is not tightly closed and in which the concentration of the formaldehyde can therefore not reach an effective level, and in which the temperature and humidity cannot be controlled, such use gives no protection from contagious diseases.

De-Germ is an unoriginal formaldehyde preparation which is marketed with unwarranted claims in such a way as to lead the user to place false dependence on it, and under a name which is not descriptive of its composition but therapeutically suggestive instead.

When the preceding report was sent to the Dale Products Co., Detroit, a reply was received stating that this firm had been absorbed by the Century Chemical Products Co., but the new owner presented no evidence which permitted a revision of the Council's report.

# Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## PETRA'S LONG AND SHORT KEW BEE BREAD

### (Sliced and Unsliced)

*Manufacturer.*—Petra Baking Company, Olean, N. Y.

*Description.*—A white bread made by the sponge dough method.

*Manufacture.*—The sponge dough ingredients, patent flour, water, lard, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, lard and powdered skimmed milk to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms are kept in strictly sanitary condition.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 34.7 |
| Ash | 0.9 |
| Protein (N × 6.25) | 9.4 |
| Fat | 1.6 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 53.1 |

*Calories.*—2.6 per gram; 74 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## BANQUET TEA—EXTRA FANCY ORANGE PEKOE

*Manufacturer.*—McCormick and Company, Inc., Baltimore.

*Description.*—A blend of India and Ceylon black fermented "Orange Pekoe" teas packed in tins.

*Manufacture.*—This orange pekoe tea is blended from hill grown India and Ceylon orange pekoe tea leaves, which are hand picked, withered, rolled, fermented and cured in the country of origin.

On arrival at the tea factory the green tea leaves are examined, weighed and spread on tats or trays of hemp cloth spread on wire screen for withering. The tea is withered from sixteen to twenty-four hours, during which process considerable moisture is lost and it becomes soft and pliable. The green leaves contain about 75 per cent moisture, the withered leaves about 37 per cent.

The withered leaves are rolled, which process breaks the leaf cells, liberating the juice and spreading it over the surface of the leaves, thus bringing it in contact with the air and permitting oxidation and fermentation. The leaf is also twisted in the rollers to reduce its bulk and improve the appearance. The rolled leaves are fermented on tables provided with shelves on which the tea is thinly spread. The leaves assume a coppery color in this operation. The aroma and color are developed in the fermentation, during which oxidation process an abundant supply of cool, humid air is provided. The fermented tea is placed in a tea drying machine composed of wire bottomed trays on which the leaves are spread and subjected to a continuous current of dry hot air from a furnace. The drying checks the fermentation. The dry tea is black.

The dry tea is hand picked to remove red leaves or other impurities and is sorted in sifting machines, which divide the tea into a number of grades, of which orange pekoe is the most highly regarded by the American trade. The graded tea is stored in bins until ready for shipment, when it is packed in lead or aluminum lined cases which are hermetically sealed.

The orange pekoe tea in the American plant is selected for thickness and rich, fine flavor, is thoroughly "vacuum" cleaned of tea dust, blended in mixing machines and packed by automatic filling machines in air tight tin containers.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 7.0 |
| Total ash | 5.9 |
| Water soluble ash | 3.8 |
| Acid insoluble ash | 0.2 |
| Alkalinity of water soluble ash....39 cc. normal alkali solution per 100 gm. | |
| Petroleum ether extract | 1.3 |
| Volatile ether extract | 0.3 |
| Crude fiber | 11.1 |
| Tannin | 13.8 |
| Caffeine | 3.6 |
| Water extract | 45.4 |
| Facing material | none |
| Exhausted tea leaves | none |
| Foreign leaves | none |
| Foreign astringent substances | none |
| Other foreign substances | none |

*Claims of Manufacturer.*—Black fermented "Orange Pekoe" tea is for tea beverage and all table uses.

## BABY RALSTON

### (Wheat endosperm and embryo)

### Baby's First Cereal Food

*Manufacturer.*—Ralston Purina Company, St. Louis.

*Description.*—A cereal mixture of farina (wheat endosperm) and wheat embryo (germ).

*Manufacture.*—Farina (wheat endosperm) and a smaller quantity of wheat germ are mixed, briefly processed at 60 C. to destroy any insect infestation, and automatically packed in cartons.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 7.1 |
| Ash | 0.4 |
| Fat (ether extract) | 1.8 |
| Protein (N × 5.7) | 15.3 |
| Crude fiber | 0.5 |
| Carbohydrates other than crude fiber (by difference) | 74.9 |
| Iron (Fe) (colorimetric method, J. Biol. Chem. **67**: 48, 1926) | 0.003 |
| Copper (Cu) (ferrocyanide method, Yoe, Photometric Chemical Analysis **1**: 182, 1928) | 0.0003 |
| Phosphorus (P) | 0.27 |
| Calcium (Ca) | 0.07 |

*Calories.*—3.8 per gram; 108 per ounce.

*Vitamins.*—A rich source of vitamins B and E, and a fair source of vitamins A and G, as a result of the presence of wheat embryo.

*Claims of Manufacturer.*—A high protein wheat cereal, designed especially for the infant's first cereal food. It contains two and one-half times as much vitamin $B_1$ as whole wheat. Its fine texture permits its use in adult smooth diets.

## CLOVERDALE SARSAPARILLA

*Manufacturer.*—Cloverdale Spring Company, Baltimore.

*Description.*—A carbonated beverage prepared from Cloverdale Mineral Water, sucrose, citric acid, and flavoring materials: oils of sweet birch and sassafras, extracts of vanilla, ginger root, pipsissewa, gentian and yarrow, and syrup of wild cherry bark; colored with caramel.

*Manufacture.*—The sucrose and citric acid and the flavoring materials in definite proportions are dissolved in Cloverdale Mineral Water (The Journal, March 5, 1932, p. 816). The solution is bottled and carbonated as described for Cloverdale Mineral Water.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 90.7 |
| Total solids | 9.3 |
| Ash | 0.1 |
| Fat | 0.0 |
| Protein (N × 6.25) | 0.0 |
| Reducing sugars, as dextrose | 1.6 |
| Sucrose (copper reduction method) | 5.6 |
| Titratable acidity as citric acid | 0.03 |
| Flavored with essential oils and extracts Undetermined | 2.0 |

*Calorics.*—0.3 per gram; 9 per ounce.

*Claims of Manufacturer.*—A bottled, carbonated sarsaparilla beverage.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Subscription price - - - - - Seven dollars per annum in advance

*Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.*

SATURDAY, MAY 21, 1932

## THE NEW ORLEANS SESSION

New Orleans is no amateur in the entertaining of a convention. On three previous occasions it provided for the annual session of the American Medical Association. This year it continued the enviable reputation that it had established. When the Association met in New Orleans in 1920, accommodations were not nearly so adequate as at present. The great auditorium takes suitable care of most of the activities of the meeting, including the exhibits and many of the sections. Other sections and the House of Delegates met in hotels.

The 1932 session followed the form of previous meetings, opening with the exhibits, the clinical lectures and the House of Delegates on Monday, May 9. While the attendance failed to reach the 1920 figure, it approximated that figure closely. Considering the extraordinary financial situation, this would seem to be cause for congratulation. The clinical lectures were exceedingly well attended and were correlated with exhibits, particularly on poliomyelitis. Many prominent orthopedic and neurologic specialists remarked that the physician who heard these lectures and studied these exhibits would no longer have the slightest excuse for failure to diagnose a case of poliomyelitis at the earliest possible moment. The scientific exhibit excited admiration for its quality and particularly for the artistic finish of the display. The technical exhibits were remarkable this year for the dignity and the scientific exactitude developed, particularly by pharmaceutical manufacturers, in the displays. Much interest was aroused by the number and quality of the exhibits of foods, an evidence of the manner in which dietetics has entered into scientific medicine.

The sessions of the House of Delegates were well attended. The interest displayed by delegates in the various discussions and resolutions indicated the feeling of responsibility of members of the House of Delegates in their deliberations for the benefit of the public and of the profession. The House of Delegates gave special attention to questions of legislative action, particularly concerning the care of veterans and the questions of maternal and infant mortality. Every reference committee of the House expressed appreciation not only of the valuable services rendered by the organization in national and state affairs but also of the personal services to physicians, which have been built up in the headquarters office.

The medical profession of New Orleans and of the state of Louisiana provided entertainment distinctive of Southern hospitality. The opening banquet for the officers and delegates, the opening session at which the President delivered his address, and the President's reception were placed in beautiful settings with excellent music and marked particularly by the light summer costumes of both men and women guests.

Perhaps the most significant feature of this session of the Association was the spirit displayed in the House of Delegates, in the various sections and in the exhibits. Here was a spirit that could not be depressed—a demonstration of the innate conviction of all that medical science must go on, that the practice of medicine is essential to human happiness, and that the physician and those associated with him in his work must carry on regardless of extraneous circumstance.

## THE IRON REQUIREMENT OF CHILDREN

While the rôle of iron in the maintenance of health has long been recognized, the possible participation of the element in biologic reactions has only recently become clearly revealed. Today we are justified in asserting that iron is an essential dietary constituent, not only for the production of blood and muscle hemoglobin but also for necessary components of all cells.[1] That is why its availability in foods and its metabolism in the body command particular attention. It is merely necessary to mention some of the questions that come to mind in this connection in order to realize the importance of the subject. How much iron is in the human body at different ages? What are the available sources of iron? How much is needed for maintenance and for growth, and how are these requirements affected by different conditions? Does the amount of iron in the food have any influence on growth?

The answer to such problems is complicated by the analytic difficulties that attend the chemical investigation of the distribution of iron. A recent writer[1] has well pointed out that the estimation of iron in biologic materials is a difficult undertaking, because a rapid and accurate method still remains to be attained, although the recent improvements that have been introduced are promising. Reported analyses of biologic materials for iron must be critically examined in the light of the analytic method employed, and some of the results in the older literature have to be discarded because of improbable analytic values. According to this reviewer, the iron content of the body at maturity is calculated at about 4.5 Gm., more or less, most of which can be accounted for by the blood. Between the first and twenty-first years (the latter age is taken only for convenience), 4,000 mg. of iron is retained. Distributed over twenty years, this amounts to an actual daily growth of 1.8 mg. of iron.

---

[1] A Recent discussion of this subject may be found in Growth and Development of the Child, Part III, Nutrition, New York, Century Company, 1932, p. 225. Some of the data considered here are taken from this new volume.

The adult has the opportunity for such a wide range in the choice of his food that the problem of his requirement of iron is perhaps not quite so circumscribed as that of the growing young child, whose regimen is dictated in larger degree by those who provide his less diversified sustenance. Until recently the only modern balance observations in childhood relating to the iron requirement have been those of Rose[2] and her collaborators at Teachers College in New York. Considerable surprise was occasioned several years ago when they reported that even in dietaries that might have been considered perfectly satisfactory the daily inclusion of one egg yolk per child resulted in better development and in slightly higher hemoglobin figures. Careful metabolism studies with respect to iron were subsequently made on one child, a girl aged 2 years and 7 months. These showed that, on a daily intake of 4.64 mg. of iron, a negative balance of 1.10 mg. resulted. The authors have estimated without further evidence that 8.50 mg. would not only be sufficient to bring about iron equilibrium but also allow for growth. This figure amounts to 0.76 mg. of iron per hundred calories of ingested food. McKay[3] has reported an average of 8.17 mg. of iron in the diets of preschool children in private homes, as compared with 4.37 mg. in the diets of children in an institution.

The most recent essay in this important field of research comes from the University of Minnesota, where Leichsenring and Flor[4] have conducted typical balance experiments in which the utilization of iron at two levels of intake was compared in healthy children ranging in age from 35 to 56 months. This is the characteristic preschool age. The results of the food analyses indicate that the iron content of foods may show considerable variation from the most commonly used figures. Diets that were planned to contain 5 and 8.5 mg. of iron actually contained only 3.25 and 6.5 mg. On a diet containing 3.25 mg. of iron, an average of 1.2 mg. was retained daily, whereas, on a diet containing 6.5 mg. of iron, 3.2 mg., or nearly three times as much as during the period of lower iron intake, was retained. The observed maintenance need of the children in this study was approximately 0.12 mg. per kilogram. On the basis of body weight, according to Leichsenring and Flor, the maintenance requirement of the child is similar to that of the adult. The iron requirement for growth, as observed in this study, was approximately 0.2 mg. per kilogram. It is customary to allow a considerable margin of safety above observed requirements of the various inorganic elements. If this margin is estimated at 50 per cent, it would make a standard allowance for children of this age of 0.48 mg. per kilogram, or 0.62 mg. per hundred calories, or a total of 8.2 mg. daily. Thus the most careful investigators in this field are in essential agreement as to the iron needs of the preschool child. One cannot depend on milk alone for an adequate supply of iron. That is why the diet chosen should be varied to include, as early as proper, generous amounts of foods that are comparatively rich in iron.

## DIGESTIVE LEUKOCYTOSIS

Circumstantial evidence has occupied an extremely important place in the evolution of conceptions in physiology. Life is maintained through the maintenance of a complex series of so-called vital equilibriums in which both physical and chemical factors have significant parts. It can be expected that a disturbance of one equilibrium is accompanied by readjustments of factors maintaining a related equilibrium. It becomes almost impossible to adjust one regulatory mechanism without eliciting a response in several different directions. However, one can point out concomitant processes, essentially unrelated, which either by their chronological parallelism or by their ease of experimental study have been mistakenly associated in a causative relation. An example of apparent misinterpretation of such associated occurrences is the usual conception of digestive leukocytosis. First described in the middle of the last century, this phenomenon was early associated with the digestion and absorption of protein. After a meal the number of circulating white blood cells was augmented markedly, the increase being greatest in the lymphocyte fraction, which frequently showed twice the concentration observed in the fasting state. Furthermore, these cells were found in greater numbers in the intestinal mucosa and in the lumen during the height of digestion and absorption. It seemed reasonable, therefore, to assume that leukocytes were concerned with the absorption of protein.

A vigorous and convincing note of doubt that there exists a functional connection between digestion per se and the frequent concomitant leukocytosis has been sounded by Garrey and Butler[1] of Vanderbilt University in Nashville, Tenn. These investigators point out that the concentration of circulating leukocytes is subject to a number of factors and that the mechanisms causing a change are surprisingly sensitive. The white cell count of normal individuals at work is uniformly between 8,000 and 9,000 per cubic millimeter, whereas the count is between 5,000 and 6,000 an hour after the subject has assumed a recumbent posture. This so-called basal level is observed as long as rest and immobility are maintained. In several experiments, after the basal level had been attained, a meal rich in protein was consumed by the subject and the prone position maintained. In no single instance did the leukocyte count rise above the basal level. A high carbohydrate meal produced like results. When the erect posture was assumed, the white cells rose to the usual higher activity level. In another experiment the erect person with the higher leukocyte count consumed a dinner and immediately lay down; there followed a progressive decrease in the concentration of white cells to the basal level.

[1] Garrey, W. E., and Butler, V.: Am. J. Physiol. **100:** 351, 1932.

To determine the influence of the filling of the stomach and change in temperature of the contents, the Nashville investigators caused resting subjects to drink large quantities of lemonade of various temperatures. Counts made immediately showed an increase over the basal level with both the cold and the hot drink, the latter showing the greater effect. Similar studies were made on laboratory animals under anesthesia. Rapid distention of the stomach with air or water is followed by an immediate increase in the leukocyte count, which disappears within half an hour. It is pointed out that "the promptness and transiency of these reactions place them definitely into the category of nervous reflexes affecting the vascular area and producing a sudden redistribution of leukocytes, with more gradual readjustment to normality." Apparently the rigorous exclusion of all factors except the one under consideration, together with the adoption of a basal level for comparison, has simplified a situation which has long been a physiologic enigma. It appears that the name digestive leukocytosis is a misnomer arising from an erroneous association of parallel but largely unrelated activities.

## DEAN LEWIS—PRESIDENT-ELECT

The House of Delegates at the New Orleans Session elected Dean Lewis, surgeon-in-chief of the Johns Hopkins Hospital, to the office of President-Elect of the American Medical Association. Through his service to scientific medicine, marked by attendance at many scientific meetings throughout the country, through his contributions to scientific medical literature, through his distinguished career in the World War, and through his contribution to the work of the American Medical Association, Dr. Lewis is widely known to the medical profession of this country and of the world. Dean Lewis was born in Kewanee, Ill., Aug. 11, 1874. He received his A.B. degree from Lake Forest University in 1895 and the degree of doctor of medicine from Rush Medical College in 1899. Early he became associated in a teaching position with his alma mater, acting as assistant in anatomy from 1900 to 1901 and associate from 1901 to 1903. He then taught surgery as an instructor from 1903 to 1919; he was associate professor from 1919 to 1920 and professor from 1920 to 1924. In 1924 he received invitations to the chairs of surgery in several important medical schools and finally accepted the professorship of surgery in the University of Illinois College of Medicine, which position he filled from January to July, 1925. Then he was appointed professor of surgery at the Johns Hopkins University School of Medicine and surgeon-in-chief to the Johns Hopkins Hospital. His membership in medical societies includes the American Surgical Association, the American Association of Anatomists, the American Physiological Society, the American Society of Clinical Surgery, the Interurban Surgical Society and the Southern and the Western Surgical Associations. During the World War he served as lieutenant colonel and was awarded the Distinguished Service Medal. He has been made a foreign member of Italian and German surgical societies and is a member of the Medical Council of the Veterans' Administration. Since the establishment

Dean Lewis, M.D.
President-Elect of the American Medical Association

of the *Archives of Surgery* in 1920, Dr. Lewis has been editor-in-chief. He is also the editor of a system of surgery and a correlated periodical, the *International Surgical Digest.* In the American Medical Association, Dr. Lewis has been a member of the House of Delegates, representing the Section on Surgery in 1915, 1916 and 1917. He was also secretary of the Section on Surgery, 1912-1913, and chairman, 1919-1920. At the Philadelphia Session he was made a member of the Council on Medical Education and Hospitals. His record and his repute promise a useful and valuable career as President-Elect and President of the Association.

## MONTGOMERY WARD & COMPANY WITHDRAWS LABORATORY SERVICE

Following publication in The Journal of the report of the laboratory of the American Medical Association relative to its survey of the urine examining service conducted by Montgomery Ward & Company, many physicians throughout the country wrote to Montgomery Ward & Company asking for an explanation of this project. In reply the following letter has been sent by the president of Montgomery Ward & Company, Mr. Sewell Avery, to many physicians and to stockholders:

> "Thank you for sending the copy of the American Medical Association Report. Upon careful investigation we have found that their position in the matter was in large part justified, although the check test which we made before adopting the service had indicated their [Universal Research Laboratories] analyses to be accurate. Because of these new developments we have discontinued the service, and are accepting no further orders."

The Journal wishes to commend the president of Montgomery Ward & Company for taking this action. It would be well if lay corporations in general could recognize the fact that the practice of medicine is distinctly a profession for trained workers and that any lay group which enters into the field is likely to develop a fiasco such as that which eventuated for Montgomery Ward & Company.

## VITAMIN B AND METABOLISM

The problem of the precise rôle of vitamin B in nutrition is by no means entirely solved. There can no longer be any doubt that it is a factor essential for physiologic welfare. This statement, based on the repeatedly demonstrated genesis of disorders when there is a shortage of vitamin B in the diet and a restoration of health when suitable sources of the vitamin are again supplied, does not reveal the details of its function. The abrupt failure of appetite, after a preliminary period, has been a conspicuous effect of lack of vitamin B, the outcome varying with the age and the species of animal under consideration. The digestive secretions are apparently not modified. Cowgill of Yale University, who has devoted much attention to this subject, has pointed out that the marked systemic manifestations characteristic of advanced cases of vitamin B deficiency suggest that the loss of the desire to eat in such instances is due as much to a generalized systemic disturbance as it is to an abnormal condition localized in the alimentary canal. Several years ago it was pointed out in The Journal that vitamin B should not be overlooked in its possible relations to certain types of gastric atony. There have long been assumptions, to say the least, that vitamin B is somehow associated with metabolism.[1] Final pronouncements are by no means yet warranted. Preliminary studies by Cowgill and his co-workers indicated that the vitamin B requirement of an animal is significantly increased when the metabolic rate is augmented. This has already been shown to be true when the voluntary food intake is increased through vigorous exercise.[2] In a more recent investigation, Himwich, Goldfarb and Cowgill[3] have demonstrated that when metabolism is heightened in the well known manner by thyroid administration the requirement for vitamin B seems to be increased. Thus, in dogs it was found that during hyperthyroidism anorexia appeared in from one half to two thirds of the time required during the control period when the diet was devoid of the vitamin. The animals successfully maintained their weights by voluntary ingestion of food only when receiving sufficient amounts of vitamin B. According to the Yale investigators, these facts may be of clinical significance. The marked loss of body weight characteristic of hyperthyroidism is well known; in the light of these experiments it is quite possible, the Yale investigators state, that vitamin B deficiency is an etiologic factor here. Administration of large amounts of vitamin B to patients with hyperthyroidism is certainly worthy of clinical trial. If one were permitted to generalize, they add, it might be said that vitamin B therapy is indicated in those conditions which are characterized by an increase in the metabolic rate.

## MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 2:25 to 2:30 p. m., over Station WBBM (770 kilocycles, or 389.4 meters), and on Friday from 1:25 to 1:30 p. m., over Station WBBM and other stations of the Columbia Broadcasting System.

The program for the week is as follows:

May 23. A Monument to the Dog.
May 25. Flies are Dangerous.
May 27. Foods and Food Advertising.

There is also a fifteen minute health talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM, Chicago.

The program for the week is as follows:

May 28. Unconsciousness.

---

# PROCEEDINGS OF THE NEW ORLEANS SESSION

## MINUTES OF THE EIGHTY-THIRD ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, MAY 9-13, 1932

## *HOUSE OF DELEGATES*

### *First Meeting—Monday Morning, May 9*

The House of Delegates convened in the Tip Top Inn of the Roosevelt Hotel, and was called to order at 10 a. m. by the Speaker, Dr. F. C. Warnshuis.

#### Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. J. D. Brook, Michigan, who reported that 101 delegates with proper credentials had registered.

On motion duly seconded and carried, Dr. John A. Card, New York, and Dr. W. E. Bannen, Wisconsin, who had lost their credentials but who were properly identified, were seated.

The Speaker, not hearing any objections, declared that the list of delegates in the hands of the Reference Committee on Credentials would constitute the roll of the House for the first meeting.

#### Adoption of Minutes of Philadelphia Session

The Secretary stated that the minutes of the Philadelphia session of the Association had been printed and put into the hands of all members of the House of Delegates, and that no corrections or amendments had been received. No objections being heard on the floor of the House, the minutes were adopted as printed, on motion of Dr. James N. Vander Veer, New York, seconded by Dr. J. W. Burns, Texas, and carried.

#### Address of the Speaker, Dr. F. C. Warnshuis

The Vice Speaker, Dr. Albert E. Bulson, Indiana, took the chair while the Speaker read his address, which was referred to the Reference Committee on Reports of Officers:

*Members of the House of Delegates:*

I am privileged again to preside during your annual deliberations. My studied endeavor will be to do so impartially and justly, and to aid you to record your action expeditiously and constructively. I solicit your assistance and forbearance.

Times change and we must change with them. The sincere student recognizes that we are at present in the vortex of readjustment along every avenue of human endeavor. New professional and public relationships are being formulated and instituted. You who represent and speak for the entire profession of scientific medicine are intimately concerned. On you who constitute this House of Delegates rests the tremendous responsibility of molding and guiding public opinion and formulating the fundamental principles that will bring about acceptable readjustments wherein all the traditions and achievements of the medical profession will be conserved and its relationship to patient and public enhanced. It is not within the province of your Speaker to lead or indicate the scope of your program. That is for this House to determine. Your Speaker's comment is intended to stress the importance of the serious duty that confronts you; to urge that you accept the commission and accomplish well directed leadership. Your constituents have the faith and confidence that your wisdom and judgment will be sound and that your final conclusions will be productive of acceptable solutions and leadership that will inspire public endorsement. Your Speaker urges that every delegate pause in thoughtful reflection and accept his rôle in initiating and applying policies that the hour and day impel.

I would urge anew the importance of the most thorough consideration of every proposal that is advanced. Reference committees frequently consider a resolution without having presented to them evidence in support or in refutation of the purpose that it embodies. There have been occasions when the action taken resulted in embarrassment to the Association, its officers and councils. Intelligent action cannot be accomplished without information and discussion. The sponsors of a resolution and those who hold opposite views or opinions should place before the reference committees all data and substantiating or refuting facts. It is the duty of delegates to appear before the reference committees on all referred business and aid in forming tenable recommendations.

It would be highly desirable if all reference committees would decline to bring in recommendations or express opinions on subjects regarding which no evidence or facts are submitted. This procedure will result in eliminating injudicious action and obviate reversal of opinions and expressions at some subsequent time.

##### COMMITTEE APPOINTMENTS

May I state anew that committee appointments are made from the list of delegates sent me by your Secretary some thirty days before the annual session. In forming committees your Speaker endeavors to give representation to every state. There are 66 committee assignments to be selected from 175 delegates. Every delegate cannot be assigned to committees. To give representation to every state is not possible. I have endeavored to be governed by the Fellowship records of each state, the number of delegates and the state's representation on boards, councils and committees.

##### EXECUTIVE SESSION

In order that the Tuesday afternoon executive session shall not aimlessly concern itself with irrelevant matters, your Speaker recommends that you authorize your Secretary, chairman of the Board of Trustees and Speaker to formulate a program of pending questions that the year's activities and experience indicate as meriting executive consideration, the consideration of other subjects to remain subject to your decision as to whether the House desires to accord to them executive attention. This policy would be conducive to well directed conclusions and is worth while considering for future sessions. Delegates informed as to the subjects presented for consideration would be prepared to discuss them and reach wise decisions. The suggestion is made for your consideration.

##### REPORTS TO STATE ORGANIZATIONS

On several previous occasions it has been recommended that delegates complete the discharge of their responsibilities and duties by rendering to their respective state organizations a detailed and explanatory report of activities of this House. This is most essential and quite desirable. State organizations stand in need of and are entitled to that information. They need to know the detailed action of this House for guidance in the administration of state organizational affairs. National unity is unattainable without such instructive and guiding knowledge.

Some delegations render detailed reports with helpful explanatory comments, some delegations merely submit an attendance report and some there are who make none. You will render a distinct contribution to this Association and to your own state if you as a delegate or delegation render specific, detailed explanatory reports on the business transactions of each session of this House. It is on the recommendation of your officers, councils and committees that your Speaker stresses this recommendation.

##### DEATHS

It is with sadness of heart and deep regret that we bow to the immutable law of life that yearly records the deaths of esteemed fellow delegates. We adjourn our annual session, return to our homes and then suddenly and all too frequently the message comes, Thrash, Polak, Hornbogen have departed from among us. It is left for us, the living, to enroll their names and deeds on the honor scroll of our Association and acknowledge their contributions to our Association, and the profession it represents. So today, in solemn recognition and tribute, your Speaker officially announces the deaths of J. O. Polak, New York; E. C. Thrash, Georgia; A. W. Hornbogen, Michigan; Donald Macrae, Iowa, and David Ross, Indiana. We have reasons for believing that these departed members maintained the sacred and honored traditions of their profession in the services they rendered. Communal life was enhanced and enriched by their ministrations.

Your Speaker acknowledges with sincere appreciation all the many courtesies and the kindly consideration you have accorded. A personal contact with this House of Delegates over a period of twenty years moves me to affirm emphatically that the affairs and interests of organized medicine rest in safe hands. Final judgment is characterized by fairness and wisdom. I am certain you will translate and effect the highest and noblest in medicine. My good wishes are yours.

### Reference Committees

The Speaker resumed the chair and appointed the following reference committees:

#### SECTIONS AND SECTION WORK

| | |
|---|---|
| F. W. Cregor, Chairman | Section on Dermatology and Syphilology |
| Bundy Allen | Florida |
| W. G. Ricker | Vermont |
| James S. McLester | Section on Practice of Medicine |
| A. J. Bedell | New York |

#### RULES AND ORDER OF BUSINESS

| | |
|---|---|
| B. L. Bryant, Chairman | Maine |
| Fred Moore | Iowa |
| R. W. Fouts | Nebraska |
| C. R. Scott | Idaho |
| W. H. Myers | Georgia |

#### MEDICAL EDUCATION

| | |
|---|---|
| Irvin Abell, Chairman | Kentucky |
| Seale Harris | Alabama |
| F. S. Crockett | Indiana |
| J. F. Burnham | Massachusetts |
| W. A. Pusey | Illinois |

#### LEGISLATION AND PUBLIC RELATIONS

| | |
|---|---|
| Grant C. Madill, Chairman | New York |
| J. F. Hagerty | New Jersey |
| Southgate Leigh | Virginia |
| C. J. Whalen | Illinois |
| A. A. Ross | Texas |

#### HYGIENE AND PUBLIC HEALTH

| | |
|---|---|
| Junius B. Harris, Chairman | California |
| C. T. Pigot | Montana |
| D. E. Sullivan | New Hampshire |
| W. F. Draper | Virginia |
| H. C. Macatee | District of Columbia |

#### AMENDMENTS TO CONSTITUTION AND BY-LAWS

| | |
|---|---|
| N. B. Van Etten, Chairman | New York |
| W. F. Donaldson | Pennsylvania |
| J. W. Amesse | Colorado |
| J. H. C | |
| H. M. | |

#### REPORTS OF OFFICERS

| | |
|---|---|
| C. E. Mongan, Chairman | Massachusetts |
| W. R. Steiner | Connecticut |
| A. R. McComas | Missouri |
| J. F. Smith | Wisconsin |
| W. A. Cook | Oklahoma |

#### REPORTS OF BOARD OF TRUSTEES AND SECRETARY

| | |
|---|---|
| W. F. Braasch, Chairman | Minnesota |
| J. N. Vander Veer | New York |
| Wells Teachnor, Sr. | Ohio |
| J. W. Burns | Texas |
| F. C. E. Mattison | California |

#### CREDENTIALS

| | |
|---|---|
| J. D. Brook, Chairman | Michigan |
| Mather Pfeiffenberger | Illinois |
| J. F. Hassig | Kansas |
| M. L. Stevens | North Carolina |
| J. N. Hunsberger | Pennsylvania |

#### MISCELLANEOUS BUSINESS

| | |
|---|---|
| J. R. Bloss, Chairman | West Virginia |
| W. R. Bathurst | Arkansas |
| H. B. Everett | Tennessee |
| Randolph Winslow | Maryland |
| G. P. Johnston | Wyoming |

#### EXECUTIVE SESSION

| | |
|---|---|
| J. W. Van Derslice, Chairman | Illinois |
| S. P. Mengel | Pennsylvania |
| A. W. Booth | New York |
| J. F. D. Cook | South Dakota |
| J. Q. Graves | Louisiana |

| | |
|---|---|
| Sergeant-at-Arms | George A. Leitner, New York |
| Assistant Sergeant-at-Arms | R. L. Green, Illinois |

### Address of President E. Starr Judd

The Speaker presented the President, Dr. E. Starr Judd, Rochester, Minn., who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

*Mr. Speaker and Members of the House of Delegates:*

The report of the Board of Trustees makes evident the increasing amount of work that is demanded of this Association each year. The activities reach into every branch of society and are becoming more important. The annual report shows a marked extension of the work of each department, and it also shows that some of these departments are taking on new duties.

In spite of extension of the work demanded of the Association and in spite of the fact that the income to the Association is reduced, nevertheless the Association is in a most satisfactory condition. The Board of Trustees, the General Manager, the Business Manager and the Editor of The Journal deserve much credit for this excellent showing of the Association the last year.

#### RESPONSIBILITIES OF THE MEMBERS OF THE HOUSE OF DELEGATES

It has been said that every man owes some of his time to the upbuilding of the profession to which he belongs, and I think that you who are members of the House of Delegates are the best illustrations of service to the medical profession. Many of you are contributing a considerable amount of time and your best efforts in the interest of organized medicine and for the benefit of society. Oftentimes your contribution must be at considerable sacrifice to yourself and to those dependent on you. You all deserve the greatest amount of credit, and I am sure that when you see the progress in preventive and curative medicine that is being made from year to year, and realize that this progress is largely the result of the activities which you have made possible through the building and maintaining of this great medical organization, you must feel well paid for your efforts and your sacrifices.

#### FUNCTIONS OF THE MEDICAL PROFESSION

The functions of members of the medical profession are, first, to advise, treat and care for those who are in need of their services; second, to plan and direct programs of preventive medicine and public health, and, third, to protect the public in every manner possible against the activities of insufficiently educated or dishonest practitioners:

1. In caring for those who are sick and injured, physicians are doing a most personal service, and whatever else happens, this must be maintained as a personal service. The profession is constantly confronted with the problem as to what is the best plan for giving adequate medical service to all of the people at all times. I think it can be said that, as a rule, the service as now furnished to society is satisfactory and adequate. Suggestions for new methods of practice are constantly being made. Many of these suggestions have to do with the economics of the practice of medicine. Others concern plans for carrying out medical service. It seems to me that organized medicine might have a more definite plan for studying these suggestions and problems. I have been informed that a committee was once in existence for the purpose of studying the various social implications of the practice of medicine but that this was some time ago. This committee was formed to give advice to the Board of Trustees, the House of Delegates and the various councils. It seems to me that a new committee might be formed, or that some member of the permanent staff might be delegated to cooperate with the bureaus and councils, for the purpose of further study of some of the plans in use in European countries, and any new plans suggested. I am not at all sure how much change, if any, should be made in our present plan, but I do think that if there was a committee working on these problems, for possibly the next five years, it might be able to suggest some changes that would help solve problems in this country. It would be possible to look into the future of medicine and to be prepared for changing conditions before they arrive, rather than to investigate conditions after the advancing tendencies have been established.

The chairman of the Committee on the Costs of Medical Care has given a preliminary report which suggests that this committee will probably recommend community health taxes.

This committee has done a tremendous amount of work and has accumulated a great deal of material that will need very careful study. In one of its reports, it reviewed an investigation of one community of 38,000 people. As I understand this report, it showed that most of these people had physical defects of one kind or another. The question that arose as I read this report was, first, What is a perfect physical specimen? and Is it necessary or advisable to attempt to correct all of these so-called defects? I believe that this illustrates some of the problems that must be carefully studied by members of the medical profession.

Caring for the sick by contract with business concerns and societies has been suggested and tried. Contract practice is probably one of the most important questions confronting the profession today. A study of the problem is being carried on by the Bureau of Medical Economics at the present time and also by some state societies. I hope that after these studies have been completed it will be possible to make some definite statement; but it is not conceivable to me that this method of practicing medicine will help to solve our present problems. Undoubtedly this form of practice will continue in certain places; it has been carried too far in other localities, and the results are not wholly satisfactory to the patient. A study of this kind necessarily involves a tremendous amount of work and time, and I feel sure that the final report on this problem will be most interesting and valuable.

There has been a tendency in some specialties and in certain communities to turn over certain cases to nurses, midwives or technicians. So far as I can see, there is no way to make the conscientious practice of medicine an easy task. And, furthermore, it has been asserted repeatedly that there are too many physicians. Although I do not believe that there are too many physicians, nevertheless I do think that in order to give the people the best care, the actual practice of medicine must be kept in the hands of physicians.

Without claiming too much, I think we may contend that we are doing very well in our present plan of practice. Progress is evident each year.

2. The second function of the medical profession concerns public health and preventive medicine. The profession may well be proud of the results accomplished in this field of endeavor. Certain infectious diseases have been greatly reduced in prevalence and severity, and others have been almost completely eradicated. Although these excellent accomplishments are largely the result of better knowledge of the exact cause of various diseases and of the application of this knowledge, nevertheless they are also due to a better understanding on the part of the people of the problems confronting medical men, and also are the result of more confidence in the profession. It seems to me, and I hope that I see clearly, that there is a better relationship between the physician and the public than there has ever been before. Undoubtedly, if this is so, it is partly due to the public meetings, and to the realization of the value of giving to the press any medical facts or information that we have. Radio programs and health talks assist in this campaign of organized medicine to keep the people informed.

Promoting public health and preventive medicine is one of the definite functions of the medical profession, and this service must not be divorced from medicine. In certain large communities it is necessary to have health officers who devote all their time to this work and who become specialists in this field. Many of the problems associated with the work must be under government supervision. All general practitioners must become familiar with the problems of public health and preventive medicine and must help in every way that they can to see that these activities are carried out adequately in their communities. At this particular time, preventive medicine is accomplishing a great deal. Organized medicine must do everything possible to escape having this function of the medical profession taken over exclusively by the government.

3. Protecting society from the irregular practices of medicine is one of the most important functions of the Association. No one realizes the tremendous commercial business carried on by these irregular concerns until such an example is offered as the one exposed this last year. It is the duty of organized medicine to expose these practices, so that the regularly constituted government authorities can prosecute the violators. The editorial departments of The Journal and of *H* are well used for this purpose when it is necessary. satisfactory exposure of activities of this kind, it seem me, is one of the real accomplishments of this associa Prosecution must be by the government. Irregular prac cannot be eliminated, but they can be reduced to a minin

GRADUATE TRAINING

The methods of practice are constantly changing, and necessary for each physician to continue to study. The ph cian's life is one of almost constant study. New things being learned each year concerning the cause and the tr ment of disease, and many of the older ideas and meth must be discarded from time to time. It is not possible one to succeed and to progress by employing methods one taught as a student some years ago. In order that the ph cian may keep abreast of the times, he must make trips large centers of medicine, and attend clinics and courses c ducted by experienced teachers where there is great abunda of clinical material. A physician who does not seek th clinics, who does not attend medical meetings, or who d not keep up his reading of medical literature, cannot do best that might be done for his patients, and cannot hope progress.

In former years it was possible in any of the larger citi on certain days, to find a good clinic where there would well chosen material presented in an interesting fashion some well known clinician or surgeon. In the present da most of these old, well established clinics have been allow to go out of existence. I think that these clinics, especial for those who are surgeons, were of great value, and I a sorry that they have not been continued. I wonder wheth it is due to some change in our conception of practice th has allowed this to take place. I wonder also whether scien and research are overshadowing the art and the human si of practice too much. I also wonder whether the full tim teaching plan for clinicians has not been a factor in allowin these important clinical days to disappear. Can a man on full time teaching appointment retain his stimulus and th industry required to make such a clinic successful? I hop that some way may be found of reviving these regular, independent clinics, so that it may again be possible to derive th benefit of a few hours with some well known physician, surgeon or specialist.

SPECIALIZATION

The House of Delegates last year requested the Council on Medical Education and Hospitals to investigate the entire subject of specialization, and to make recommendations looking to the establishment of proper qualifications of physicians who wish to engage in special practice. Specialization has been greatly overdone and not only is responsible for less satisfactory results but also has a tendency to increase the cost. I believe the best specialists will be those who have spent some time in general practice. One of the difficulties seems to be in the medical schools where the students are directed to some special field, and where students say it is difficult at the present time to obtain a well rounded out training such as would equip one for general practice.

Nevertheless there are many fields of medicine in which the general practitioner cannot hope to be sufficiently trained. Special knowledge, special training and an abundance of experience are required to make a specialist. One of the duties of organized medicine is to make it possible for society in general as well as the medical profession to find out who are qualified specialists in the various fields. Furthermore, I believe that there is nothing more important than the regulation of specialization and the proper qualification of specialists at the present time.

Some of the specialties have established qualifying boards and are attempting to further the plan of certifying as to special qualifications. I have been informed that representatives of several clinical specialties have suggested that the National Board of Medical Examiners state its present attitude concerning the part it is willing to take in assisting the qualifying boards in the clinical specialties. The subject of specialization has been discussed in a preliminary manner at several informal conferences by the representatives of certain specialties, and a subcommittee of the National Board of Medical Examiners. The consensus in these conferences has been that it is desirable that some dependable method of certification be devised by each of the special clinical fields, and, further, that there should be some central organization of the several qualifying bodies to insure better coordination. It has been suggested also that the American Medical Association become responsible for the publication of official lists of qualified specialists.

Several sections of the Association have already accomplished a good deal toward determining and regulating the qualifications for specialization in particular fields. It seems to me that it is advisable to do all that we possibly can to promote this activity among the sections. If the American Medical Association, cooperating with the Association of American Medical Colleges, state boards of medical licensure, the National Board of Medical Examiners, the American College of Surgeons, the American Board for Ophthalmic Examinations, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology, and such other specialty boards as may be developed can officially regulate specialization, it will have accomplished much.

### HOSPITAL BEDS FOR VETERANS

One of the most important problems before society and the medical profession is the one dealing with the best plan for care of war veterans. Some of these men are sick and must be cared for. The medical profession is willing and anxious to see that the best medical attention possible is provided for them. It wants them to have exactly the same care that all other orders of society are given. It does not want them to be pauperized and to be placed in hospitals when they are not sick. It seems to me that the federal government has built enough hospitals. There are many unoccupied beds in civilian hospitals that might well be used in the care of veterans who are sick.

It is fortunate that these affairs are in the hands of an industrious and intelligent committee. The medical profession can feel hopeful and confident that the efforts of its committee, combined with those of the American Legion and the American Hospital Association, will bring forth the proper solution of this problem.

### NEW BUILDING

The thing this Association needs as much as anything else is a new building for its headquarters offices. The Board of Trustees is studying this problem and I hope it will soon find that it is feasible to proceed. More space is needed adequately to house the departments as they are at the present time. Progress is being hampered in many ways by not having sufficient and good space in which to work. Not only would a new building, properly planned and adequately equipped, permit the activities of organized medicine to be more effectual, but the added possibilities for progress and development would help to keep the American Medical Association in its position of the largest and most important medical organization in the world.

## Address of President-Elect Edward H. Cary

The Speaker then presented the President-Elect, Dr. Edward H. Cary, Dallas, Texas, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

*Mr. Speaker and Members of the House of Delegates:*

I come to you after a year of partial observation of the medical activities of our country. There are many questions which will undoubtedly be brought to your attention; hence it will be unnecessary for me to mention more than three or four which I would like to accentuate.

### DUAL RELATIONSHIP OF PHYSICIANS

I have been greatly impressed with the dual responsibility of the doctor. His personal relationship to patients is so vital that it must always be kept in the foreground. To preserve this intimate quality of service embodies human happiness by meeting human needs and should be harmonized with the continued flexible growth of the medical profession. Our civic relations demand that we take part in public health service. We are forced to become interested in the activities of lay organizations which are striving to solve health problems. Many of these problems have arisen from an awakened public health consciousness, which has come from the revelations of medical research. The public is groping for a more widespread application of what it believes to be medical discoveries. We are loath to believe that the enlightened public desires to interfere with the private practice of medicine, but social trends which involve medical practice should be studied, for, after all, medicine is a social function.

### APPOINTMENT OF A COMMITTEE TO COOPERATE WITH BUREAU OF MEDICAL ECONOMICS

The profession must not be deterred from contributing its weight of opinion and battling for leadership in lay organizations which are interested in health matters. In my opinion, the Board of Trustees should be authorized to appoint a committee to cooperate with the Bureau of Medical Economics, this committee to study and aid in reconciling conflicting views related to the practice of medicine. These may include better cooperation on the part of the members of the profession, and a better understanding of the needs of the people as related to the individual practitioners and public health service, developing a formula outlining to what extent public health service will be acceptable and practical. This committee should consider, too, the numerous studies being made by the profession and others of the so-called high cost of medical care, reconciling conflicting views as they may affect the practice of medicine, and making available the plan most adaptable to conditions in communities seeking relief. This study should include methods of handling indigents and those of limited financial resources as a civic responsibility. For the underprivileged, some plan should be developed whereby the family may budget its health needs, an effort being made to eliminate the middleman but to conserve the right of the patient to select his doctor and to preserve the right of the physician to open opportunity on equal terms with his brother practitioner.

This committee should help to develop a plan of cooperative medicine for greater efficiency, applicable to each community, suggesting methods of practice for the purpose of making certain a correct diagnosis, partnerships between doctors being unnecessary. The fee should be commensurate with the ability of the patient to pay. There would be, through the committee, several helpful minds added to the Bureau of Medical Economics.

### DEVELOPMENT OF POSTGRADUATE INSTRUCTION

I am also impressed with the need of a comprehensive effort on the part of the Council on Medical Education and Hospitals to develop postgraduate instruction. There are many component and associated medical societies which are now carrying on intensive postgraduate work. These societies need the active aid of a committee representing the American Medical Association through the Council on Medical Education and Hospitals. This committee can suggest appropriate and nonconflicting dates, can list available instructors, and can suggest subject matter most needed for elucidation. Regional clinical meetings for intensive study should be encouraged in certain geographic localities, to discourage a multiplicity of like endeavors which are apt to lessen professional interest or conflict with the meetings of the state medical societies.

Efforts should be made to cooperate with special societies now doing postgraduate work, and to encourage all such efforts when accomplished through our medical organization. It would seem highly desirable that the House of Delegates suggest to the Board of Trustees that a committee be appointed, and, with the aid of the Council on Medical Education and Hospitals, accomplish these suggestions with nominal cost to the American Medical Association.

### NEED FOR CONSERVING RESOURCES

Though I am sure that the economic trend is strongly for retrenchment throughout the land, we should consider seriously any suggestion that would retard the growth of our organization. We have a tremendous task ahead of us to preserve the rights and privileges that have come through years of endeavor. I fear that the average member of our profession gives little

This committee has done a tremendous amount of work and has accumulated a great deal of material that will need very careful study. In one of its reports, it reviewed an investigation of one community of 38,000 people. As I understand this report, it showed that most of these people had physical defects of one kind or another. The question that arose as I read this report was, first, What is a perfect physical specimen? and Is it necessary or advisable to attempt to correct all of these so-called defects? I believe that this illustrates some of the problems that must be carefully studied by members of the medical profession.

Caring for the sick by contract with business concerns and societies has been suggested and tried. Contract practice is probably one of the most important questions confronting the profession today. A study of the problem is being carried on by the Bureau of Medical Economics at the present time and also by some state societies. I hope that after these studies have been completed it will be possible to make some definite statement; but it is not conceivable to me that this method of practicing medicine will help to solve our present problems. Undoubtedly this form of practice will continue in certain places; it has been carried too far in other localities, and the results are not wholly satisfactory to the patient. A study of this kind necessarily involves a tremendous amount of work and time, and I feel sure that the final report on this problem will be most interesting and valuable.

There has been a tendency in some specialties and in certain communities to turn over certain cases to nurses, midwives or technicians. So far as I can see, there is no way to make the conscientious practice of medicine an easy task. And, furthermore, it has been asserted repeatedly that there are too many physicians. Although I do not believe that there are too many physicians, nevertheless I do think that in order to give the people the best care, the actual practice of medicine must be kept in the hands of physicians.

Without claiming too much, I think we may contend that we are doing very well in our present plan of practice. Progress is evident each year.

2. The second function of the medical profession concerns public health and preventive medicine. The profession may well be proud of the results accomplished in this field of endeavor. Certain infectious diseases have been greatly reduced in prevalence and severity, and others have been almost completely eradicated. Although these excellent accomplishments are largely the result of better knowledge of the exact cause of various diseases and of the application of this knowledge, nevertheless they are also due to a better understanding on the part of the people of the problems confronting medical men, and also are the result of more confidence in the profession. It seems to me, and I hope that I see clearly, that there is a better relationship between the physician and the public than there has ever been before. Undoubtedly, if this is so, it is partly due to the public meetings, and to the realization of the value of giving to the press any medical facts or information that we have. Radio programs and health talks assist in this campaign of organized medicine to keep the people informed.

Promoting public health and preventive medicine is one of the definite functions of the medical profession, and this service must not be divorced from medicine. In certain large communities it is necessary to have health officers who devote all their time to this work and who become specialists in this field. Many of the problems associated with the work must be under government supervision. All general practitioners must become familiar with the problems of public health and preventive medicine and must help in every way that they can to see that these activities are carried out adequately in their communities. At this particular time, preventive medicine is accomplishing a great deal. Organized medicine must do everything possible to escape having this function of the medical profession taken over exclusively by the government.

3. Protecting society from the irregular practices of medicine is one of the most important functions of the Association. No one realizes the tremendous commercial business carried on by these irregular concerns until such an example is offered as the one exposed this last year. It is the duty of organized medicine to expose these practices, so that the regularly constituted government authorities can prosecute the violators. The editorial departments of The Journal and of *Hygeia* are well used for this purpose when it is necessary. The satisfactory exposure of activities of this kind, it seems to me, is one of the real accomplishments of this association. Prosecution must be by the government. Irregular practices cannot be eliminated, but they can be reduced to a minimum.

### GRADUATE TRAINING

The methods of practice are constantly changing, and it is necessary for each physician to continue to study. The physician's life is one of almost constant study. New things are being learned each year concerning the cause and the treatment of disease, and many of the older ideas and methods must be discarded from time to time. It is not possible for one to succeed and to progress by employing methods one was taught as a student some years ago. In order that the physician may keep abreast of the times, he must make trips to large centers of medicine, and attend clinics and courses conducted by experienced teachers where there is great abundance of clinical material. A physician who does not seek these clinics, who does not attend medical meetings, or who does not keep up his reading of medical literature, cannot do the best that might be done for his patients, and cannot hope to progress.

In former years it was possible in any of the larger cities, on certain days, to find a good clinic where there would be well chosen material presented in an interesting fashion by some well known clinician or surgeon. In the present day, most of these old, well established clinics have been allowed to go out of existence. I think that these clinics, especially for those who are surgeons, were of great value, and I am sorry that they have not been continued. I wonder whether it is due to some change in our conception of practice that has allowed this to take place. I wonder also whether science and research are overshadowing the art and the human side of practice too much. I also wonder whether the full time teaching plan for clinicians has not been a factor in allowing these important clinical days to disappear. Can a man on a full time teaching appointment retain his stimulus and the industry required to make such a clinic successful? I hope that some way may be found of reviving these regular, independent clinics, so that it may again be possible to derive the benefit of a few hours with some well known physician, surgeon or specialist.

### SPECIALIZATION

The House of Delegates last year requested the Council on Medical Education and Hospitals to investigate the entire subject of specialization, and to make recommendations looking to the establishment of proper qualifications of physicians who wish to engage in special practice. Specialization has been greatly overdone and not only is responsible for less satisfactory results but also has a tendency to increase the cost. I believe the best specialists will be those who have spent some time in general practice. One of the difficulties seems to be in the medical schools where the students are directed to some special field, and where students say it is difficult at the present time to obtain a well rounded out training such as would equip one for general practice.

Nevertheless there are many fields of medicine in which the general practitioner cannot hope to be sufficiently trained. Special knowledge, special training and an abundance of experience are required to make a specialist. One of the duties of organized medicine is to make it possible for society in general as well as the medical profession to find out who are qualified specialists in the various fields. Furthermore, I believe that there is nothing more important than the regulation of specialization and the proper qualification of specialists at the present time.

Some of the specialties have established qualifying boards and are attempting to further the plan of certifying as to special qualifications. I have been informed that representatives of several clinical specialties have suggested that the National Board of Medical Examiners state its present attitude concerning the part it is willing to take in assisting the qualifying boards in the clinical specialties. The subject of specialization has been discussed in a preliminary manner at several informal conferences by the representatives of certain specialties, and a subcommittee of the National Board of Medical Examiners. The consensus in these conferences has been that it is desirable that some dependable method of certification be devised by each of the special clinical fields, and, further, that there should be some central organization of the several qualifying bodies to insure better coordination. It has been suggested also that the American Medical Association become responsible for the publication of official lists of qualified specialists.

Several sections of the Association have already accomplished a good deal toward determining and regulating the qualifications for specialization in particular fields. It seems to me that it is advisable to do all that we possibly can to promote this activity among the sections. If the American Medical Association, cooperating with the Association of American Medical Colleges, state boards of medical licensure, the National Board of Medical Examiners, the American College of Surgeons, the American Board for Ophthalmic Examinations, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology, and such other specialty boards as may be developed can officially regulate specialization, it will have accomplished much.

### HOSPITAL BEDS FOR VETERANS

One of the most important problems before society and the medical profession is the one dealing with the best plan for care of war veterans. Some of these men are sick and must be cared for. The medical profession is willing and anxious to see that the best medical attention possible is provided for them. It wants them to have exactly the same care that all other orders of society are given. It does not want them to be pauperized and to be placed in hospitals when they are not sick. It seems to me that the federal government has built enough hospitals. There are many unoccupied beds in civilian hospitals that might well be used in the care of veterans who are sick.

It is fortunate that these affairs are in the hands of an industrious and intelligent committee. The medical profession can feel hopeful and confident that the efforts of its committee, combined with those of the American Legion and the American Hospital Association, will bring forth the proper solution of this problem.

### NEW BUILDING

The thing this Association needs as much as anything else is a new building for its headquarters offices. The Board of Trustees is studying this problem and I hope it will soon find that it is feasible to proceed. More space is needed adequately to house the departments as they are at the present time. Progress is being hampered in many ways by not having sufficient and good space in which to work. Not only would a new building, properly planned and adequately equipped, permit the activities of organized medicine to be more effectual, but the added possibilities for progress and development would help to keep the American Medical Association in its position of the largest and most important medical organization in the world.

## Address of President-Elect Edward H. Cary

The Speaker then presented the President-Elect, Dr. Edward H. Cary, Dallas, Texas, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

*Mr. Speaker and Members of the House of Delegates:*

I come to you after a year of partial observation of the medical activities of our country. There are many questions which will undoubtedly be brought to your attention; hence it will be unnecessary for me to mention more than three or four which I would like to accentuate.

### DUAL RELATIONSHIP OF PHYSICIANS

I have been greatly impressed with the dual responsibility of the doctor. His personal relationship to patients is so vital that it must always be kept in the foreground. To preserve this intimate quality of service embodies human happiness by meeting human needs and should be harmonized with the continued flexible growth of the medical profession. Our civic relations demand that we take part in public health service. We are forced to become interested in the activities of lay organizations which are striving to solve health problems. Many of these problems have arisen from an awakened public health consciousness, which has come from the revelations of medical research. The public is groping for a more widespread application of what it believes to be medical discoveries. We are loath to believe that the enlightened public desires to interfere with the private practice of medicine, but social trends which involve medical practice should be studied, for, after all, medicine is a social function.

### APPOINTMENT OF A COMMITTEE TO COOPERATE WITH BUREAU OF MEDICAL ECONOMICS

The profession must not be deterred from contributing its weight of opinion and battling for leadership in lay organizations which are interested in health matters. In my opinion, the Board of Trustees should be authorized to appoint a committee to cooperate with the Bureau of Medical Economics, this committee to study and aid in reconciling conflicting views related to the practice of medicine. These may include better cooperation on the part of the members of the profession, and a better understanding of the needs of the people as related to the individual practitioners and public health service, developing a formula outlining to what extent public health service will be acceptable and practical. This committee should consider, too, the numerous studies being made by the profession and others of the so-called high cost of medical care, reconciling conflicting views as they may affect the practice of medicine, and making available the plan most adaptable to conditions in communities seeking relief. This study should include methods of handling indigents and those of limited financial resources as a civic responsibility. For the underprivileged, some plan should be developed whereby the family may budget its health needs, an effort being made to eliminate the middleman but to conserve the right of the patient to select his doctor and to preserve the right of the physician to open opportunity on equal terms with his brother practitioner.

This committee should help to develop a plan of cooperative medicine for greater efficiency, applicable to each community, suggesting methods of practice for the purpose of making certain a correct diagnosis, partnerships between doctors being unnecessary. The fee should be commensurate with the ability of the patient to pay. There would be, through the committee, several helpful minds added to the Bureau of Medical Economics.

### DEVELOPMENT OF POSTGRADUATE INSTRUCTION

I am also impressed with the need of a comprehensive effort on the part of the Council on Medical Education and Hospitals to develop postgraduate instruction. There are many component and associated medical societies which are now carrying on intensive postgraduate work. These societies need the active aid of a committee representing the American Medical Association through the Council on Medical Education and Hospitals. This committee can suggest appropriate and nonconflicting dates, can list available instructors, and can suggest subject matter most needed for elucidation. Regional clinical meetings for intensive study should be encouraged in certain geographic localities, to discourage a multiplicity of like endeavors which are apt to lessen professional interest or conflict with the meetings of the state medical societies.

Efforts should be made to cooperate with special societies now doing postgraduate work, and to encourage all such efforts when accomplished through our medical organization. It would seem highly desirable that the House of Delegates suggest to the Board of Trustees that a committee be appointed, and, with the aid of the Council on Medical Education and Hospitals, accomplish these suggestions with nominal cost to the American Medical Association.

### NEED FOR CONSERVING RESOURCES

Though I am sure that the economic trend is strongly for retrenchment throughout the land, we should consider seriously any suggestion that would retard the growth of our organization. We have a tremendous task ahead of us to preserve the rights and privileges that have come through years of endeavor. I fear that the average member of our profession gives little thought to the value of this collective effort. I sometimes wonder whether we realize what it means to the individual physician. To make effective this effort to advance the science and practice of medicine and to preserve its endowments, the Association should be made as strong financially as it is numerically. It is true that we have deliberately defended the people from many abuses, and such efforts have been rewarded with suits for large sums of money. Legal defense is always expensive, but the members of the profession in the localities immediately affected are helpless if the American Medical Association does not assume the task of exposure and defense.

No other organization in the world is giving to its members so much. Its scope embraces literature, news and information of all kinds, not to speak of the associational advantages. The *British Medical Journal,* for instance, which in size and importance is next to ours, costs $15 annually. Other foreign journals of less importance cost relatively the same, while the annual income of the average American physician is greater. The new revenue bill will undoubtedly carry increased postal rates which will add greatly to the cost of The Journal. It would seem unwise to jeopardize our progress by reducing the cost of The Journal to our members. Any reduction would be a backward step and would actually amount to very little to the individual member. I hope that any constituent society which has expressed itself in favor of a reduction in the present price of The Journal will reconsider its decision, for the beneficent influence of the organization should not be curtailed. If the medical profession is to meet its obligations and responsibilities successfully in this new commercial age, it must be able in all respects, and fully fortified.

#### NEW HOME FOR THE ASSOCIATION

The American Medical Association should and can be properly housed. An organization as strong as ours in its financial resources might be able now to take advantage of the greatest opportunity it will ever have to acquire the most desirable property suited to its needs, at a cost so low that what would seem an extravagance under normal conditions might be provident now.

#### DELIBERATIONS OF THE HOUSE

The wisdom of the House of Delegates manifested in the past justifies the hope that its deliberations will aid in solving many problems, either during this session or through the orderly procedure of referring to your distinguished Board of Trustees matters for which you are unable to find a ready solution.

It is my earnest desire to cooperate with you, and the profession generally, in advancing our professional prestige and welfare, as well as the science and practice of medicine. I am convinced that professional effort, when carried on in orderly fashion, offers to the people of this country one of the most beneficent influences they have for the common good.

### Remarks of Dr. Paul Wolff

Dr. Morris Fishbein introduced Dr. Paul Wolff of Berlin, who addressed the House as follows:

*Mr. Chairman:*

It is a great privilege for me to convey to you and my esteemed colleagues of America my heartfelt thanks for the honor which you have conferred on me by asking me to come here to lecture to you. And I need hardly say that it is with the greatest enthusiasm that I accepted the invitation; for it has given me the opportunity not only of explaining the world situation of drug addiction as my special subject but, in connection with this, particularly the situation in Germany and the opinions of the German medical corps. At the same time I have been entrusted by the Deutscher Aerztevereinsbund, which is the professional union of all physicians in my country, and is the equivalent in Germany of the American Medical Association, to convey to you all the heartiest greetings as a means of establishing a closer and firmer relationship between your country and mine. And this will lead, I hope, to a furthering of the scientific work and professional interest of both nations.

### Greetings to House

Dr. Olin West, Secretary, read a telegram of greeting from the British Medical Association and from Dr. G. E. de Schweinitz, a Past President.

## REPORTS OF OFFICERS

### Report of the Secretary

Dr. Olin West then presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of the following: The part containing amendments to the Constitution and By-Laws introduced by Dr. D. E. Sullivan, New Hampshire, by Dr. J. Gurney Taylor, Wisconsin, and by Dr. Isaac A. Abt, Section on Diseases of Children, was referred to the Reference Committee on Amendments to the Constitution and By-Laws; the resolution from the Michigan State Medical Society was referred to the Reference Committee on Legislation and Public Relations; the resolution introduced by Dr. G. Henry Mundt, Illinois, was referred to the Reference Committee on Medical Education; the part pertaining to dual membership was referred to the Reference Committee on Constitution and By-Laws, and the resolution introduced by Dr. Albert Soiland, California, and adopted at the Philadelphia Session, was referred to the Reference Committee on Constitution and By-Laws.

### Report of the Board of Trustees

The Secretary presented the report of the Board of Trustees, which was referred to the Reference Committee on Reports of the Board of Trustees and Secretary.

### Report of the Special Committee on Legislative Activities

Hearing no objection, the Speaker ruled that the report of the Special Committee on Legislative Activities would be presented at the executive session, Tuesday afternoon, with the exception of the portion referring to amendment to the By-Laws, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

### Report of the Judicial Council

Dr. George E. Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Rules and Order of Business.

### Report of the Council on Medical Education and Hospitals

General Merritte W. Ireland, Washington, D. C., presented the report of the Council on Medical Education and Hospitals, which was referred to the Reference Committee on Medical Education.

### Report of the Council on Scientific Assembly

Dr. Roger S. Morris, Cincinnati, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

### Good Wishes and Good Cheer to Ill Confrère

Dr. William G. Ricker, Vermont, moved that a telegram of good wishes be sent to Dr. J. Gurney Taylor, Wisconsin, absent because of illness. The motion was seconded by Dr. Arthur C. Morgan, Pennsylvania, and carried.

## NEW BUSINESS

### Resolution on the Care of Veterans

Dr. H. H. Shoulders, Tennessee, presented the following resolution on the Care of Veterans, which was referred to the Reference Committee on Legislation and Public Relations:

*Resolved,* By the House of Delegates of the American Medical Association that, in furtherance of the plan and policy of a resolution with regard to the governmental policy of rendering medical and hospital benefits to veterans with non-service connected disabilities, adopted in Philadelphia, at the 1931 session, the principles of which we hereby reaffirm, the House of Delegates hereby gives its approval to the draft of a proposed amendment to the World War Veterans' Act, 1924, which is as follows:

"An Act to Amend the World War Veterans' Act, 1924

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

"Section 1. That Paragraph 10 of Section 202 of the World War Veterans' Act, 1924, approved June 7, 1924, as amended by Acts approved March 4, 1925, July 2, 1926, and July 3, 1930, is hereby amended by striking therefrom the following: "The director is further authorized, so far as he shall find that existing Government facilities permit, to furnish hospitalization and necessary traveling expenses incident to hospitalization to veterans of any war, military occupation, or military expedition, including those women who served as Army nurses under contracts between April 21, 1898, and February 2, 1901, and including persons who served overseas as contract surgeons of the Army at any time during the Spanish-American War, not dishonorably discharged, without regard to the nature or origin of their disabilities."

"SECTION 2. The World War Veterans' Act, 1924, is further amended by adding thereto the following:

"(1) Each honorably discharged veteran of any war, military expedition, or military occupation with ninety days or more of actual service, shall be entitled to the following disability benefits for disabilities not resulting from injury or disease suffered or contracted in military or navy service:

"A. A cash benefit of $12.50 per week during any period of total disability from disease or injury.

"B. A hospital benefit of $4.00 per day during any period of actual and necessary hospitalization.

"(2) Such benefits shall be payable to the veteran upon satisfactory proof of the disability, furnished by the veteran to the Veterans' Bureau, upon forms and in accord with rules to be prescribed by the Director of the Veterans' Bureau; each such proof to include the supporting statement of an attending physician of good standing and repute, and, in the case of hospital benefit, the certificate of the superintendent or person in charge showing actual confinement in a hospital approved by the Director for service to veterans;

"(3) PROVIDED, no cash benefit shall be payable under this section to a veteran for any condition for which he is paid disability allowance for total permanent disability under the amendment to the World War Veterans' Act of July 3, 1930; and no benefits under this section shall be paid to any veteran for any disability resulting from his own wilful misconduct; nor for any disability for which the veteran is entitled to hospitalization under paragraph 10 of section 202 of the World War Veterans' Act, as amended by this Act, in a hospital under the control of the Veterans' Bureau.

"(4) Whenever malingering or fraudulent collusion on the part of an attending physician is suspected by the Director, any veteran claiming benefits under this section may be ordered by the Bureau to a Veterans' Bureau or to a veterans' hospital for examination, observation and report as to the existence of a condition entitling him to the benefits claimed, pending compliance with which order payment of benefits shall be suspended; and in all cases hospital records of the claimant shall be open to the inspection of the Bureau, and the claimant shall be subject to examination under the provisions of section 203 of the World War Veterans' Act, 1924, as amended.

"(5) The Director of the Veterans' Bureau shall furnish to each living veteran who may be entitled to benefits under this section a "Disability Benefit Certificate," reciting the benefits provided herein and the terms and conditions under which they may be paid and received, together with a blank form on which application and proof for such benefits may be made. The Director shall enforce the provisions of this section through and as a department of the Division of War Risk Insurance of the Veterans' Bureau.

"Section 3. The provisions of Section 1 hereof shall take effect six months from the date of this enactment; and the benefits provided in Section 2 shall accrue and commence six months from the date of enactment."

Be it further

*Resolved*, That the proper officers of this association be instructed to take steps to present this matter properly to every important local Legion post in the United States, with a view to securing their endorsement of the amendment. Be it further

*Resolved*, That the Board of Trustees be authorized and requested to place sufficient funds at the disposal of the Legislative Committee to carry on this activity, and, be it further

*Resolved*, That the Legislative Committee be empowered and directed to employ a full time personnel for the purpose of carrying this work forward. Be it further

*Resolved*, That the Legislative Committee be instructed to present the proposed amendment to the Congress of the United States for consideration, when a reasonable number of local legion posts have endorsed it. Be it further

*Resolved*, That, in the interest of harmony, the Legislative Committee is empowered to make changes in the wording of this proposed amendment except that there shall be no abandonment or compromise of the fundamental and underlying principles; to wit:

1. The cessation of the hospitalization of veterans with non-service connected disabilities, except as set out in the first part of paragraph 202-10 of the World War Veterans Act, and in the proposed amendment.

2. That the veteran himself shall have the right to select his physician and hospital, subject to the reasonable regulations and approval of the Veterans' Bureau.

## Resolution on Increase of Personnel and Budget

Dr. C. S. Gorsline, Michigan, presented the following resolution on Increase of Personnel and Budget, which was referred to the Board of Trustees:

WHEREAS, It appears from the suggestion in the address of the President-Elect and from a careful perusal of the published report of the director of the Bureau of Medical Economics that an economic emergency exists in the affairs of practitioners of medicine in general, and

WHEREAS, It is apparent that substantial progress has been made in the study of medical economic problems and that it appears that certain phases of our economic problems demand the earliest possible consideration in order that the medical profession shall have placed at its disposal the necessary facts for intelligent action, and

WHEREAS, These problems are, in the order of their apparent importance, (1) workmen's compensation, (2) health insurance, and (3) contract practice; and

WHEREAS, The present personnel and finances seem to be inadequate to accomplish speedy results, therefore be it

*Resolved*, That the Board of Trustees of the American Medical Association be requested by this House of Delegates to provide such additional increase in budget and personnel as may be required to secure this important information at the earliest possible date consistent with completeness and accuracy of the data assembled.

## Resolution on the Appointment of a Committee to Study Birth Control

Dr. J. D. Brook, Michigan, presented a resolution on the appointment of a committee to study birth control. On motion of Dr. J. W. Van Derslice, Illinois, seconded and carried, the resolution was laid on the table for consideration at the executive session Tuesday afternoon.

## Resolution Requesting Reduction in the Subscription Rate

Dr. Edgar A. Hines, South Carolina, presented the following resolution requesting reduction in the subscription rate for THE JOURNAL from $7 to $5, which was referred to the Board of Trustees:

WHEREAS, Economic conditions are such that many members of the medical profession find it increasingly difficult to pay $7 subscription for THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, therefore be it

*Resolved*, By the Greenville County Medical Society in Session April 4, 1932, that a request be made of the American Medical Association to reduce the subscription of THE JOURNAL from $7 to $5 as soon as practicable.

E. A. HINES.
J. H. CANNON.

NOTE.—This resolution was submitted to the House of Delegates of the South Carolina Medical Association, April 19, 1932, and the delegates to the American Medical Association are directed to transmit the same to the House of Delegates of the American Medical Association for their consideration.

## Resolution on Hospital and Health Insurance Societies in Cuba

Dr. William R. Molony, California, presented the following resolution on hospital and health insurance societies in Cuba, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The development of so-called "Hospital and Health Insurance Societies" has taken on so great a development in Cuba that the standards of medical practice seemingly have been seriously endangered through such organizations; and

WHEREAS, It is desirable that full and accurate information should be placed at the disposal of the medical profession of the United States concerning these Cuban organizations because in them there is an expression of the dangers which confront medical practice through the establishment of such institutions; now therefore be it

*Resolved*, By the Executive Committee of the California Medical Association that the California Medical Association Council be requested to instruct the delegation from this constituent state association of the American Medical Association to present this resolution to the American Medical Association House of Delegates at its next annual session at New Orleans; and be it further

*Resolved*, That the recommendation be made to the American Medical Association House of Delegates that, through appropriate action, steps be taken by the American Medical Association to secure full information concerning these Cuban so-called "Health and Insurance Societies" and clubs, inasmuch as such information could be of great value to organized medicine as represented by the American Medical Association and its constituent state units.

## Resolution on Publication of a Digest of Major Medicolegal Decisions

Dr. Molony also presented the following resolution on publication of a digest of major medicolegal decisions to be printed in annual volumes, which was referred to the Board of Trustees:

WHEREAS, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION prints in each of its issues a digest of major medicolegal decisions; and

WHEREAS, Such digests, if brought out in booklet form, year by year, with proper index and cross references, could be of very great value to members of the medical and legal profession; now, therefore, be it

*Resolved*, By the House of Delegates of the California Medical Association at its sixty-first annual session, that it requests the House of Delegates of the American Medical Association to consider the advisability of recommending to the Board of Trustees of the American Medical Association the publication, in the form of annual volumes, of these medicolegal digests which are printed in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION; and be it further

*Resolved,* That a copy or copies of such volume, as approved by the House of Delegates and by the Board of Trustees of the American Medical Association, be sent each year to each of the constituent state associations.

### Communication on Appréciation of Auxiliary

The Speaker referred to the Reference Committee on Miscellaneous Business the following communication:

If the House of Delegates would send a letter of appreciation to the Auxiliary it would do more to stimulate interest than anything that you and I and all the Auxiliary leaders put together could do. Their letter after being read at the meeting could probably be placed in the Exhibit.

The meeting adjourned at 12:20 p. m., to reconvene at 9:30 Tuesday morning, May 10.

*(To be continued)*

# *Medical News*

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

## ARIZONA

**State Medical Election.**—Dr. Clarence Gunter, Globe, was installed as president of the Arizona State Medical Association at its recent annual meeting, and Dr. Nelson C. Bledsoe, Tucson, was made president-elect. Dr. Delamere F. Harbridge, Phoenix, was reelected secretary. The next annual session will be held at Tucson in April, 1933.

## CALIFORNIA

**Licenses Revoked and Restored.**—*California and Western Medicine* reports the following changes in the status of licentiates made at the regular meeting of the state board of medical examiners in Los Angeles, February 1-4: Dr. George H. Bland, Fresno, license revoked, February 2, for violation of probation based on narcotic charges; Dr. William B. Hamilton, license revoked, February 2, based on revocation of his Utah license on which he obtained his California reciprocity license; Dr. Alfred G. R. Castles, Los Angeles, placed on probation for five years, February 2, based on advertising contrary to law; Dr. Cary A. Snoddy, Vallejo, and Dr. Aubrey H. Staples, Oakland, placed on probation for five years without narcotic privileges, having been found guilty, February 2, of narcotic indiscretions; Dr. Roy L. Buffum, Long Beach, whose license was restored, February 2, was placed on probation for a period of five years without alcohol or narcotic privileges; Dr. John H. Seifert, San Diego, whose license was restored, February 1, was placed on probation.

**New State Medical Library.** — The new state medical library, authorized by the 1931 legislature for the purpose of aiding physicians, particularly in rural districts, to keep up to date in their practice, was started, May 1, with the cooperation of the University of California Medical School. The library will be maintained in two branches, one at the medical school in San Francisco, and one at the medical department in Los Angeles. From these centers medical journals and books will be sent to practicing physicians in any part of the state on request. Funds for the support of the project will come from the surplus account of the state board of medical examiners which is made up from medical license fees and taxes. An advisory committee has been appointed to supervise the work of the "packet library." Members of the committee are President Robert Gordon Sproul of the university; Dr. John H. Graves, president, state board of health; Dr. Percy T. Phillips, president, state board of medical examiners; Dr. Langley Porter, dean of the medical school in San Francisco, and Dr. George H. Kress, dean of the medical department in Los Angeles. Miss Francis Van Zandt will be the librarian.

## ILLINOIS

**Society News.**—Dr. Edward S. Murphy, Dixon, was elected president of the Illinois Tuberculosis Association at its recent annual meeting in Danville.——The Livingston County Medical Society was recently addressed at Pontiac, among others, by Drs. William H. Holbrock and William A. Malcolm, both of Peoria, on urologic and obstetric subjects, respectively.

### Chicago

**Rongetti's License Revoked.** — The state department of registration and education revoked the license of Amante Rongetti, May 4, on the ground of his conviction of manslaughter (The Journal, Aug. 30, 1930, p. 668).

**Society News.**—At the meeting of the Chicago Pediatric Society, May 17, the speakers included Drs. Charles A. Aldrich, Winnetka, on "An Anomaly of the Brain," and Bert I. Beverly on "Congenital Atresia of the Duodenum."——The Chicago Society of Internal Medicine will be addressed, May 23, among others, by Drs. Chauncey C. Maher on "Effects of Intravenous Quinidine Sulphate on the Fibrillating Auricle," and Harry A. Singer, "Valvular Pneumoperitoneum."——The Chicago Gynecological Society was addressed, May 20, among others, by Dr. George F. Hibbert on "Significance of the Streptococcus in Trichomonas Vaginalis Vaginitis."

## INDIANA

**Course at City Hospital.**—Indiana University School of Medicine and the graduate committee of the Indiana State Medical Association are making arrangements for a series of courses, June 16-17, at Indianapolis City Hospital. The study will be arranged especially for the general practitioner so that he may have a review in the fundamentals and a knowledge of new technic in treatment.

**Society News.**—Dr. John R. Hurley, Muncie, addressed the Delaware-Blackford County Medical Society, April 19, on "Scarlet Fever Problem with Emphasis on Prevention."——At the meeting of the LaPorte County Medical Society, April 21, Drs. Alois B. Graham and Joseph W. Ricketts, Indianapolis, discussed "Anorectal Diseases."——Dr. Goethe Link, Indianapolis, talked on "Disturbances of the Thyroid Gland," April 11, before the Randolph County Medical Society.——"Chronic Constipation" was the subject of Dr. Arthur G. Funkhouser, Indianapolis, before the Grant County Medical Society, Marion, April 26.——Dr. Roy Lyman Sexton, Washington, D. C., addressed the Tippecanoe County Medical Society at Lafayette, May 5, on "Colon Disturbances and Involvements Including Endocrine Aspects."——The Indianapolis Medical Society will be addressed, May 24, by Dr. Ralph M. Waters, Madison, Wis., on "Carbon Dioxide Absorption from Anesthetic Atmospheres"; the society will be addressed, May 31, by Drs. Cleon A. Nafe and Homer G. Hamer on "Surgical Treatment of Acute Empyema" and "Various Causes of Perineal Swellings."——Dr. Will J. Martin, Kokomo, was elected president of the Indiana Tuberculosis Association at its twenty-first annual meeting in Indianapolis.——The Parke-Vermillion Counties Medical Society was reorganized, April 20.

## KANSAS

**State Medical Election.**—Officers of the Kansas Medical Society are Drs. Paul S. Mitchell, Iola, president, whose term expires December 31; James D. Colt, Sr., Manhattan, president-elect, whose term expires Dec. 31, 1933; Jacob F. Gesell, Wichita, vice president; George M. Gray, Kansas City, treasurer, and John F. Hassig, Kansas City, secretary. The society will hold its seventy-fifth annual meeting in Lawrence, May 2-4, 1933.

## LOUISIANA

**State Medical Election.**—Dr. Roy B. Harrison, New Orleans, was installed as president of the Louisiana State Medical Society at its fifty-third annual meeting, in New Orleans, May 9-10. Dr. Carl A. Weiss, Baton Rouge, was made president-elect. Other officers of the society are Drs. James T. Nix, Jr., New Orleans, Charles M. Horton, Franklin, and Willis P. Butler, Shreveport, vice presidents. Dr. Paul T. Talbot, New Orleans, was reelected secretary. The next annual meeting of the association will be held in Lake Charles.

## MARYLAND

**Dinner to Dr. Gardner.** — Dr. William Sisson Gardner, professor of gynecology, University of Maryland Medical School, Baltimore, and chief of the gynecological staff of Mercy and University Hospitals, Baltimore, was guest of honor at a dinner, May 5, given in recognition of his many years' service in the medical school. Dr. Frank D. Sanger was toastmaster and Dr. Thomas K. Galvin was in charge of the dinner. Speakers included Drs. James Douglas Crane, Ishpeming, Mich.; James M. H. Rowland, dean, University of Maryland Medical School; John Ruhräh, professor of pediatrics; Charles F. Blake and Julius Friedenwald. Dr. Gardner in 1885 graduated from the College of Physicians and Surgeons, Baltimore, now a part of the University of Maryland.

**Stillbirths in Maryland.**—Recent statistics indicate that of the total of 31,271 births reported in Maryland during 1931, 1,966, or 6.3 per cent of the infants, were born dead. One source of information stated that this number probably represents but a fraction of the actual number of infants still-born in a year, as some cases probably are not reported. Figures for the state last year show one stillbirth for every fifteen live births, or a rate of 67.1 per thousand live births. The infant mortality for Maryland for 1931 shows that one of every twelve children born alive died during its first year of life, or a rate of 79.6 per thousand live births. The ratio of stillbirths to live births is higher among the Negro population than among the white, the 1931 rates being 100.4 per thousand live births for Negro infants and 57.9 for white. The stillbirth rates for the individual counties range from 140.9 per thousand live births in Talbot County to 30.5 in Garrett County, with a median rate of 70.8. Maryland is the only state that requires the registration of "all products of conception."

## MASSACHUSETTS

**License Restored.**—At a meeting of the state board of registration in medicine, April 14, it was voted to restore to Dr. Charles Grapek his license to practice medicine in Massachusetts. The license had been revoked, April 2, 1931 (The Journal, May 23, 1931, p. 1804).

**Dr. Hubbard Honored.**—Dr. Frank A. Hubbard, for more than fifty-two years a practicing physician of Taunton, was given a dinner, April 6, on the occasion of his eightieth birthday. A silver pitcher and tray were presented to Dr. Hubbard by William H. Reed, editor of the Taunton Gazette. Dr. Arthur R. Crandell, Taunton, presided. The speakers were Hon. Andrew J. McGraw, mayor of Taunton; Mr. Reed, and Drs. William M. Conant, Charles G. Mixter, Philemon E. Truesdale, Ralph C. Larrabee, Zabdiel B. Adams and John W. Bartol.

**State Medical Meeting in Boston.**—The one hundred and fifty-first meeting of the Massachusetts Medical Society will be held in Boston, June 8-10, with headquarters at the Hotel Statler, under the presidency of Dr. Halbert G. Stetson, Greenfield. The Shattuck lecture will be delivered, Wednesday evening, by Dr. Frank B. Mallory, professor of pathology, Harvard University Medical School, on "Cirrhosis of the Liver." Dr. Samuel B. Woodward, Worcester, will give the annual discourse on "The Story of Smallpox in Massachusetts." Guest speakers on the program will include Drs. Frank H. Krusen, Philadelphia, on "Physical Therapy, An Aid to Routine Medical and Surgical Practice"; George A. Wyeth, New York, "Treatment of Growths by Electro-Surgery"; Irving W. Potter, Buffalo, "Elective Version, with Lantern Slide Demonstration"; Edward J. Rogers, Pittsford, Vt., "Silicosis in Vermont Granite Cutters and Slate Workers," and George P. Muller, Philadelphia, "Mortality of Acute Appendicitis." Medical and surgical clinics will be held at the Boston City Hospital.

## MINNESOTA

**Society News.**—Dr. Harry F. Bayard, Minneapolis, addressed the Hennepin County Medical Society, April 13, on "Diagnosis of Chronic Ulcerative Colitis," and Dr. Morris H. Nathanson, "Pericarditis with Effusion: Treatment with Pneumopericardium."——Dr. Owen H. Wangensteen, Minneapolis, among others, read a paper before the Minnesota Academy of Medicine, May 18, on "Therapeutic Considerations in the Management of Acute Intestinal Obstruction."——The Red River Valley Medical Society was addressed at its April meeting in Crookston by Drs. Henry O. Ruud, Grand Forks, on "Diagnosis and Treatment of Lateral Sinus Thrombosis," and Russell Gates, Minot, "Case Histories and X-Ray Diagnosis."

## MISSOURI

**Tanned with Identical Numerals.**—The use of artificial light rays to tan new-born babies and their mothers with identical numerals was adopted at the General Hospital, Kansas City, April 9. The tanning of baby and mother is done before the mother or child is taken from the delivery room, thus eliminating any chance of error in infant identification. The numerals remain visible for about ten days.

**State Medical Meeting in Jefferson City.**—The seventy-fifth annual meeting of the Missouri State Medical Association will be held in Jefferson City, May 23-26, with headquarters at Junior College, under the presidency of Dr. John F. Harrison, Mexico. The program will include symposiums on diseases of the kidney, carcinoma of the breast, syphilis, diseases of the ear, nose and throat. Guest speakers will include Drs. Edward H. Cary, Dallas, Texas, President, American Medical Association, on "Relation of the Modern Doctor to the Public"; Burton J. Lee, New York, "Indications for Surgery and the Indication for Irradiation in the Treatment of Cancer"; Elexious T. Bell, Minneapolis, "A Clinical and Pathological Study of Primary Hypertension"; William S. Middleton, Madison, Wis., "Syphilis of the Circulatory System." Other speakers on the program include Drs. Martin Hayward Post, Jr., St. Louis, "Incipient Cataract: Its Incidence and Care"; Arthur L. Anderson, Springfield, "Value of Routine Basal Metabolism in the Examination of Patients"; Benjamin Landis Elliott, Kansas City, "Diagnosis of Cerebellar Disease"; Edward Sanborn Smith, Kirksville, "Problem of the Narcoleptic"; Lloyd B. Clinton, Carthage, "Pediatric Surgery," and John F. Chandler, Oregon, "Dispensing as an Art." The twenty-fourth annual meeting of the Missouri Society of Medical Secretaries will be held, Wednesday. Among others on the program will be Dr. Edward J. Goodwin, secretary, state medical association, who will present a report on legislation.

## NEBRASKA

**Study of Intestinal Allergy.**—The University of Nebraska College of Medicine was recently given a research fund of $1,500 by Merrell and Company of Cincinnati for a special study of the flora of the intestine of individuals suffering with allergy. The work is being carried out by Dr. Charles P. Baker, under the supervision of Dr. John T. Myers, professor of bacteriology and public health, and Dr. Ernest L. MacQuiddy, who is in charge of the allergy work of the university.

**Fifty Years in Practice.**—The Thayer County Medical Society gave a dinner in honor of Dr. Charles C. Snowden, Davenport, April 21, in recognition of his completion of fifty years in the practice of medicine, all of which time has been spent in Davenport. Dr. Harry J. Newell, Alexandria, spoke in behalf of the medical society; Dr. Harry E. Potter, Fairbury, in behalf of friends, and Dr. Edward W. Rowe, Lincoln, on the advances in medicine during the last fifty years. Dr. Miles J. Breuer, Lincoln, spoke on "Types of Anemia That Do Not Respond to Standard Methods of Treatment."

## NEW JERSEY

**Illegal Practitioners Prosecuted.**—The following persons were recently prosecuted by the state board of medical examiners for practicing medicine without a license:

Sarah E. Wilson of Pitman.

Carmelo Cerina, a bone setter of Glassboro.

Ernest Palmaffy, naturopath of Newark.

Maria Capra, midwife of Union City.

Robert C. Bieri, electrotherapist, Union City.

Michael Palazzi, chiropractor, Netcong.

Albert R. Korhnack, electrotherapist of Gloucester.

Anna Fazekas of Franklin.

Voorhees G. Cheathem, licensed chiropractor of Plainfield, was convicted of practicing medicine without a license. He exceeded his chiropractic license by giving electrical treatments.

Abraham E. Sandman, electrotherapist, Atlantic City.

John F. Johnson, Atlantic City.

Frederick S. Fennel, licensed chiropractor, Morristown. He exceeded his chiropractic license by giving electrical treatments and drugs.

Mary Miller, licensed chiropractor, Paterson. She exceeded her chiropractic license by giving electrical treatments and drugs.

Nancy Kehoe. She gave electrical treatments under direction of Mary Miller, D.C., by whom she was employed as a nurse.

Wilbur Leib, druggist of Cape May.

Beverly R. McPhail, druggist, Maywood.

Dr. Krakor Tekian, Newark.

## NEW YORK

**Health at Utica.**—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended May 7, indicate that the highest mortality rate (23.4) appears for Utica, and the rate for the group of cities as a whole, 11.8. The mortality rate for Utica for the corresponding period last year was 21.9, and for the group of cities, 12.1. The annual rate for eighty-five cities for the eighteen weeks of 1932 was 12.5, as against a rate of 13.6 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits, or that they have a large Negro population, may tend to increase the death rate.

### New York City

**Society News.**—Dr. Jacques W. Maliniak was elected president of the recently organized Society of Plastic and Reconstructive Surgery.——A symposium on the common cold constituted the meeting of the Medical Society of the County of

New York, April 25; the speakers were Drs. Alphonse R. Dochez, Anna W. Williams, Harlow Brooks, Marcus A. Rothschild, Joseph Harkavy and Samuel J. Kopetzky.

**Medical Center to Open September 1.**—The New York Hospital-Cornell University Medical Center, covering three entire blocks along the East River between Sixty-eighth and Seventieth streets, which has been under construction since the autumn of 1929, will open September 1. The present New York Hospital, the Lying-In Hospital and the Manhattan Maternity and Dispensary will close their present plants about August 1 to move into the new center. Cornell University Medical College will begin to move at the end of the present school term in June and will open the fall term in the new buildings, September 29. More than half of the 1,000 beds in the hospital will be ready for occupancy at the outset.

**Personal.**—In recognition of forty years of service to the University and Bellevue Hospital Medical College, colleagues of Dr. William J. Pulley, clinical professor of medicine, gave a dinner in his honor, April 23.——Dr. Richard T. Atkins was appointed professor of otolaryngology at University and Bellevue Hospital Medical College, it was announced, April 25; Dr. Lee M. Hurd was appointed emeritus professor of laryngology, and Dr. John McCoy, emeritus clinical professor of laryngology.——Dr. Phoebus A. Levene, member of the Rockefeller Institute for Medical Research, has been elected a member of the Deutsche Akademie der Naturforscher in Halle, on the occasion of the celebration of the centenary of the death of Goethe.

**Public Psychiatric Service.**—Results of the first year of the psychiatric service of the city department of health in the Bellevue-Yorkville Health Demonstration are disclosed in the 1931 report of the demonstration. This is the first complete mental hygiene unit established by the department; it was opened in November, 1930; last year 141 patients were treated. The objectives are to carry out an educational mental hygiene program and to be of service to patients referred by physicians or nurses in the health center clinics. The educational work has been carried on by means of group discussion meetings every two weeks and by individual conferences with nurses. The direct service to the patients has necessitated cooperation with a large number of social agencies and with district schools.

## OHIO

**Personal.**—Dr. James H. Park has been appointed health officer of Ashtabula, succeeding Dr. Azro J. Pardee, resigned. ——Dr. Floyd S. Meck, Cleveland, was appointed a member of the state board of medical examiners, April 21, to succeed Dr. Thomas H. George.

**State Medical Election.**—Dr. Herbert M. Platter, Columbus, was installed as president of the Ohio State Medical Association at its recent annual meeting; Dr. Clyde L. Cummer, Cleveland, was made president-elect; Dr. James A. Beer, Columbus, treasurer. Don K. Martin, Columbus, is the secretary.

**Medical Alumni Reunion.**—The alumni of the University of Cincinnati College of Medicine will hold its annual medical reunion, June 10. Friday and Saturday mornings, June 10-11, the hospitals of Cincinnati will provide clinics to demonstrate technic, unusual cases and methods of diagnosis. The golf tournament will be held Friday afternoon. A feature of the annual banquet this year will be the silver anniversary reunion of the class of '07, and the golden anniversary of the class of '82. Dr. Dudley W. Palmer is president of the Alumni Association, and Dr. Robert H. Kotte, secretary.

## PENNSYLVANIA

**Hospital News.**—The new $100,000 nurses' home and training school of the Delaware County Hospital was dedicated, April 24. The three-story brick building is the gift of Mrs. May F. Fitzgerald, Lansdowne, in memory of her husband, the late Thomas M. Fitzgerald.

**Health Survey in Delaware County.**—A resolution was adopted at the March meeting of the Delaware County Medical Society requesting the U. S. Public Health Service to conduct a health survey of the county. As set forth in the resolution, this survey would better provide for the present and future health of the citizens of Delaware County, create and build effective methods of combating and preventing epidemics of disease, obtain the maximum of coordination and efficiency from individuals and the voluntary health agencies, obtain accurate information on all matters pertaining to the public health, and prevent and correct overlapping of individual and organized effort.

**Society News.**—The Pennsylvania Safety Conference was held at the Penn-Harris Hotel, May 12-13, in Harrisburg. Included among the speakers were Dr. Alice Hamilton, Boston, on "Industrial Poisonings in Pennsylvania," and John B. Andrews, Ph.D., New York, "Legislation for the Prevention of Occupational Disease." "A Year of Safety" and "Occupational Diseases" were topics for discussion at this meeting also. ——Dr. George G. Ornstein, New York, addressed the Cambria County Medical Society in Cresson, May 12, among others, on "Diagnosis and Treatment of Pulmonary Tuberculosis."—— Dr. Willis F. Manges, Philadelphia, addressed the Eleventh Councilor District Medical Society, May 19, on "Relation of Sinus Infection to Pulmonary Diseases."——The Delaware County Medical Society was addressed, May 12, by Drs. Ezra A. Whitney and Horace H. Hunsicker, Elwyn, on "Studies in Epilepsy with Emphasis on Dehydration."—— Mental hygiene and child health was the general topic for discussion before the Allegheny County Medical Society, May 17, in Pittsburgh; the speakers were Drs. Charles H. Henninger and Theodore O. Elterich.——Dr. Charles Howard Marcy addressed the Erie County Medical Society in Erie, May 3, on "Collapse Therapy in the Treatment of Pulmonary Tuberculosis."——The Crawford County Medical Society was addressed in Meadville, May 9, by Dr. Joseph H. Barach, on "Focal Infection."

### Philadelphia

**Society News.**—Dr. Robert Tilden Frank, New York, will address the Philadelphia County Medical Society, May 25, on "The Hormones Controlling the Sex Functions in Women."

**Hospital News.**—The Woman's Hospital of Philadelphia opened the first unit of its new building, April 13. It contains the laboratories and also private and ward floors. The second unit will be completed in June, at which time the hospital will be able to accommodate 160 patients. This hospital is a result of the merger of the Woman's Hospital of Philadelphia, established in 1861, and the West Philadelphia Hospital for Women, established in 1889. Both institutions were managed by women, and had staffs of women physicians. Their services are available for women and children only and the institution will be carried on along the same lines.——A new surgical ward was opened at St. Luke's and Children's Homeopathic Hospital, April 4, the gift of the junior auxiliary of the hospital association.

## SOUTH CAROLINA

**State Medical Election.**—Dr. James R. Young, Anderson, was installed as president of the South Carolina Medical Association at its recent annual meeting in Columbia. Dr. Robert E. Abell, Chester, was made president-elect, and Dr. Edgar A. Hines, Seneca, was reelected secretary. The next annual session of the association will be held in Spartanburg.

**Society News.**—Drs. Paul H. Ringer and William Pinkney Herbert, Asheville, N. C., addressed the Columbia Medical Society, recently, on treatment of tuberculosis.——Dr. Charles H. Young, Anderson, addressed the February meeting of the Anderson County Medical Society on diseases of the thyroid gland.——Dr. George R. O'Daniel has been appointed health officer of Dorchester County.——The South Carolina-Savannah Valley Medical Society, comprising the counties of Allendale, Hampton and Barnwell, was recently formed. Dr. G. W. I. Loadholt, Fairfax, was made president, and Dr. Herbert A. Gross, Barnwell, secretary.——Dr. John B. Setzler, Columbia, health officer of Richland County, was elected president of the South Carolina Public Health Association, April 19, succeeding Dr. Hugh B. Senn, Beaufort.

## UTAH

**Personal.**—Dr. Louis E. Viko was recently appointed health officer of Salt Lake City, succeeding Dr. Willard Christopherson, who has returned to private practice. Extension of departmental activities in the board of health is being planned, especially in the fields of tuberculosis and child hygiene. The department is also preparing a revised sanitary code and a revised foods code for submission to the city commission.

**Joint Program to Limit Tuberculosis.**—Plans announced at the annual meeting of the Utah Tuberculosis Association, April 28, indicate that the association and health department of Salt Lake City will cooperate with other agencies in a program to improve the care and limit the incidence of tuberculosis. The plans, as outlined in an address by Dr. Louis E. Viko, health commissioner of Salt Lake City, provide that the tuberculosis association will furnish part of the time of its nurses to the city health department for the purpose of doing tuberculosis follow-up nursing in the city. It is understood that this is a demonstration by the tuberculosis association, rather than a permanent arrangement. Necessary records will be kept in the health department by the tuberculosis nurse. Cases of tuberculosis reported to the health department will be referred to the tuberculosis nurse, who will contact the reporting physician to secure his permission and instructions for aiding in the isolation and proper care of the cases.

## GENERAL

**Courses in "Sight-Saving."**—To prepare teachers and supervisors of children having seriously defective vision, summer courses will be offered by four universities, in cooperation with the National Society for the Prevention of Blindness, as follows:

University [illegible] June 18-July 26.
University [illegible] ıgo, Chicago, June 27-August 5.
Teachers [illegible] New York, July 5-August 12.
State Tea [illegible] 5-August 12.

Information concerning these courses may be secured from the respective universities or from the National Society for the Prevention of Blindness, 450 Seventh Avenue, New York.

**American Association for the Study of Goiter.**—The annual meeting of the American Association for the Study of Goiter will be held in Hamilton, Ont., June 14-16. Dr. Marcus O. Shivers, Colorado Springs, Colo., will give the presidential address on "Prophylaxis in Diseases of the Thyroid Gland." Speakers on the program will include Drs. Charles H. Mayo, Rochester, Minn., on "The Past and Possible Future of the Thyroid Gland"; Andre Crotti, Columbus, Ohio, "Etiology of Endemic Goiter—Rabbit Experimentation"; James B. Collip, Montreal, Que., "Physiology of the Parathyroid Gland"; Lewellys Barker, Baltimore, "Relationship of the Sympathetic System to Thyroid Disease," and Gordon S. Fahrni, Winnipeg, Manit., "Management of Hyperthyroidism Associated with Other Diseases." Announcement of the winner of the annual prize award essay contest will be made at this meeting.

**Health Authorities of North America.**—The State and Provincial Health Authorities of North America will hold its forty-seventh annual conference at the Willard Hotel, Washington, D. C., June 2-6. Dr. Theodore B. Beatty, state health commissioner of Utah, is president of the conference. Among the speakers at this meeting will be Dr. Wilson G. Smillie, professor of public health administration, Harvard School of Public Health, Boston, on "Field Studies in Common Colds"; Dr. Malcolm R. Bow, deputy minister of health of Alberta, Canada, "Health Work in Alberta"; Dr. Theodore B. Appel, secretary of health, state department of health, Pennsylvania, "Stream Pollution Control and Water Conservation"; Drs. Polk Richards and Len L. Culp, Minneapolis, "Trachoma," and W. F. Walker, D.P.H., of the American Public Health Association, "Appraisal of Rural Health Work." Meeting simultaneously with this group will be the health officers with the U. S. Public Health Service.

**Revised Standard for Clinical Thermometers.**—A recommended revision of the commercial standard for clinical thermometers was circulated, February 24, for acceptance by those participating in the conferences, chiefly representatives of manufacturing interests. Acceptances have been received representing a satisfactory percentage of production, an announcement states. The bureau of standards, U. S. Department of Commerce, has indicated that, in accordance with the recommendation of the standing committee, this revision of the commercial standard, to be known as CSI-32, will become effective June 1. The bureau states further: those who were active in drafting this specification believe that although it is not an excessively high standard, in that manufacturers should experience no great hardship in meeting its requirements, it does insure thermometers that meet the ordinary demands of accuracy and reliability. Furthermore, they believe that thermometers which fail to pass the required tests are inferior and unsuitable for clinical use. It is expected, the announcement continues, that these standards will be followed as far as circumstances permit.

**Medical Bills in Congress.**—*Changes in Status:* H. R. 4724 has been vetoed by the President, proposing to extend the benefits of hospitalization and the privileges of the soldiers' homes on certain persons who served in the Quartermaster Corps or under the jurisdiction of the Quartermaster General during the war with Spain, the Philippine insurrection, or the China relief expedition. President Hoover said, in part: "I cannot concur in a proposal to single out one class of civilian employees who served during certain periods of hostilities and confer upon them a right to the benefits of hospitalization and domiciliary care provided by law for veterans of our wars. Such proposal would be establishing a precedent which, in all justice, would call for similar legislation in behalf of other civilians. It would ultimately involve the government in hundreds of millions of expenditures by the usual accretions of wider spread inclusions of new and borderland groups." Hearings were begun, May 12, by a subcommittee of the Senate Committee on the Judiciary, on S. 4436, a bill introduced by Senator Hatfield to amend the existing law relating to the dissemination of information and devices for the prevention of conception. *Bill Introduced:* S. 4547, by Senator Copeland, New York, to extend to June 30, 1933, the period within which application may be made for retirement under the Disabled Emergency Officers' Retirement Act.

**Biologists Thank Mayor and City Council.**—More than 500 members of the Federation of American Societies for Experimental Biology meeting in Philadelphia signed a letter of thanks, which was presented to Mayor Cermak of Chicago, in person, May 4, by Prof. Anton J. Carlson of the University of Chicago. The members of the society expressed their appreciation of the services of the mayor and city council of Chicago in insuring a continuance of medical research in the reputable medical schools and laboratories of that city, which scientific work had been seriously handicapped last July by the efforts of certain individuals and societies opposed to animal experimentation. About that time an ordinance was passed without the knowledge of the universities and laboratories which provided that unclaimed dogs should be disposed of on the premises, thus making it impossible for the laboratories to obtain unclaimed dogs. More recently, however, an amendment was introduced by Alderman Arvey and almost unanimously passed by the city council, which provided that reputable medical schools and laboratories might apply to the president of the city board of health for a certain number of dogs which on his recommendation would be turned over to these laboratories by the chief of police. Although it has been made more difficult, the universities have been enabled thus to continue experimentation. It was for invaluable service in bringing this amendment about that the foregoing letter of thanks was presented to the mayor of Chicago.

**Society News.**—At the annual meeting of the American Physiological Society, April 29, Dr. Arno B. Luckhardt, Chicago, was elected president, and Dr. Frank C. Mann, Rochester, Minn., secretary. The next annual session will be held at Cincinnati, probably in April, 1933.——The officers for the ensuing year of the American Association of Pathologists and Bacteriologists are Drs. Elexious T. Bell, Minneapolis, president; Oswald T. Avery, New York, president-elect, and Howard T. Karsner, Cleveland, secretary. The next annual session will be held at Washington, D. C., May 2-3.——Dr. G. Canby Robinson, New York, was elected president of the Association of American Physicians at its recent annual meeting, and Dr. James H. Means, Boston, reelected secretary. The next annual session will be held at Washington, D. C., May 2-3.——At the annual meeting of the American Gastro-Enterological Association, May 2, Dr. Burrill B. Crohn, New York, was made president, and Dr. Charles G. Lucas, Louisville, Ky., reelected secretary.——Harold C. Bradley, Ph.D., Madison, Wis., was elected president of the American Society of Biological Chemistry, and Howard B. Lewis, Ph.D., Ann Arbor, Mich., secretary, at the society's annual meeting, April 29. The next annual session will be held in Cincinnati.——Dr. Arthur L. Bloomfield, San Francisco, was elected president of the American Society for Clinical Investigation, May 2, and Dr. Herrmann L. Blumgart, Boston, elected secretary. The next annual session will be held in Washington, D. C. in May.

## FOREIGN

**Dr. Mellanby Given Prize.**—The Cameron Prize of the faculty of medicine of the University of Edinburgh has been awarded to Dr. Edward Mellanby, professor of pharmacology, University of Sheffield. The prize is given for additions to practical therapeutics.

**Society News.**—The annual congress and exhibition of the Royal Sanitary Institute of England will be held at Brighton, July 9-16.——The International Congress Against Rheumatism, which was to have been held in Rome in May, has been postponed indefinitely in view of the present economic condition.——Lord Moynihan, London, will deliver the Romanes lecture for 1932 at the University of Oxford, June 1. His subject will be "The Advance of Medicine."——The Royal Institute of Public Health held its annual congress in Belfast, May 10-16. Discussions were grouped under state medicine and municipal hygiene; industrial hygiene, women and children and the public health; tuberculosis, and pathology, bacteriology and biochemistry.

*(From Our Regular Correspondent)*

April 23, 1932.

### The Menace of Complete Medical Socialism Passes

The growth of medical socialism in England, in the form of the various free clinics for maternity and child welfare, tuberculosis and venereal diseases and in the National Health Insurance Acts, has often been commented on in previous letters to The Journal. Finally came, two years ago, the scheme of the British Medical Association of a medical service to be provided by the state for all. This scheme was produced not because of any desire of the profession or of the Association for complete medical socialism but as a lesser evil than some scheme which might be foisted on the profession by the socialist government then in office. With the crushing defeat of the socialist party when the country began to realize the ruin threatened by their prodigal expenditure, the menace of complete medical socialism has passed for the time, but it remains a possibility of the future. At the Paddington Medical Society an interesting debate took place on "A State Medical Service," which means complete medical socialism. The protagonists of all parties took part. Mr. Somerville Hastings, laryngologist and member of parliament, who may be regarded as the leader of the socialist party in the medical profession, opened the debate. He desired that everybody, without consideration of ability to pay, should receive in illness the best attention which medical science could give. He also wanted more preventive medicine. He regarded the scheme of the British Medical Association as a useful step in the right direction, but he wanted to go further—to have a complete state service, complete, unified and free. He did not want compulsion for either patient or physician, but a service so good that people would readily avail themselves of it. He thought that such a scheme should appeal to the medical profession, for it was the most socialistic of all the professions. Physicians' discoveries were by tradition broadcast to the world, and their charges were made according to the means of their patients. A desirable extension of the latter principle was that people should pay for medical services not in hard cash but in rates and taxes based on individual means. During the last fifty years the general practitioner had been continuously robbed of clinical material and of interest in his work. One group of diseases after another had been taken from him. He might diagnose an infectious disease, but its treatment was carried out in a fever hospital. Venereal diseases were treated largely in clinics, and the treatment of school children has been taken from him. In 1927 the *British Medical Journal* said: "There are no fewer than seventeen departments of clinical activity for which provision is made in this sectional way under the auspices of the local authorities." Further, as soon as a patient entered the hospital the general practitioner lost all contact with him, and the complexity of the modern treatment of disease necessitated that patients would increasingly go to the hospital. Municipal hospitals were developing side by side with the voluntary hospitals and, because of the financial backing of the state, were becoming formidable rivals. It was the spirit of the age to provide for the needs of the community by cooperative means. There was a strong case for the treatment of all sorts of disease in special clinics—rheumatism, orthopedic conditions, heart disease in children and even cancer. But more coordination was needed so as to insure that the patient fell into the right compartment. In his view the general practitioner was needed for every family, and for him to be excluded from many of the medical schemes was a disaster. Medical research was now confined to the big hospitals. If the profession were unified it could take part in it and produce better results.

Sir Ernest Graham Little (dermatologist and member of parliament) led the individualist opposition. Mr. Hastings had not described what sort of general practitioner the socialist scheme envisaged. Did it contemplate the sort of practice now known as insurance or panel? Under it the choice of physician and place to go for treatment were taken from the patient, but the British public could not be forced to go where they did not want to go. A state medical service would not be conducive to the progress of medicine but to standardization, for a state possessed neither soul nor mind. Loss of independence and of competition were serious drawbacks. Moreover, the cost would be prohibitive. What was the great advantage of the voluntary hospital system? Mr. Hastings admitted that most of the research had been done there. What distinguished it from state-controlled institutions? First, individual management. How much better was their status than that of the municipally managed hospitals? Economy would certainly not be secured by handing them over to government management.

Dr. G. C. Anderson, deputy-medical secretary of the British Medical Association, did not agree with either of the previous speakers, but he went further with the socialistic idea, because now that the state had provided a medical service for the country, he felt sure that it would be extended. The British Medical Association had sketched out a complete scheme, not because it imagined that the socialist government (in power at the time) would introduce a whole-time state medical service, but because it feared that the developments which were going on might proceed on wrong lines, by an extension of the "clinic" rather than of the "panel" system. What was wrong with the insurance system was its limitations; but it was out of the question to revert to the previous order of things. He wanted the insurance physician to have further opportunities for extending his knowledge by contact with the hospitals in his area. In all its negotiations with the government the association had tried to make insurance practice approximate as closely as possible to private practice.

### Proposal to Abolish the Patenting of Discoveries

The council finds that the present state of the law with regard to patenting discoveries is unsatisfactory. The view generally held in this country is that discoveries for the treatment of disease should not be patented but available to every one to use for the benefit of humanity. But this voluntary abstention from patenting has the result that British medical research may be exploited in other countries and patented in this country. This has occurred in the case of vitamin D. By means of British research it was produced in a potent form by ultraviolet irradiation of ergosterol. But when our manufacturers wanted to apply the discovery, a British patent, granted to Professor Steenbock of Wisconsin, was found to be an obstacle. The council says that this patent is founded on the earlier and unpatented discoveries of other workers, particularly British, and holds that it is unreasonable that Professor Steenbock should be able to control the results of so much previous and subsequent work. It seems that he has transferred his rights to the University of Wisconsin and that these rights are granted in respect of a somewhat vague process for the irradiation of any foodstuffs. The council's remedy is to abolish the patenting of therapeutic discoveries entirely, as has been done in some countries. A previous attempt was made to get over the difficulty by a proposal for the compulsory dedication in the public interest and under state administration of all therapeutic discoveries. But a committee appointed by the board of trade to consider the matter would not agree to this. They found that medical opinion was not unanimous on the undesirability of patenting. It was suggested that it was not ethically worse to reward research that reduced human suffering than to pay a surgeon a fee. Moreover, some manufacturing chemists urged that the proposed restriction would discourage research and encourage secrecy as a method monopoly. In the end, the committee decided against compulsory dedication because it would operate adversely on British industry and discriminate against British research workers.

### Irish Hospitals and Sweepstakes

The immense sum, mostly from other countries, derived by the Irish hospitals from sweepstakes has aroused attention in England to this method of raising money, which at present would be illegal. In the House of Commons the home secretary, Mr. Samuel, stated that there had been five of these sweepstakes between November, 1930, and March, 1932, and the public in the United Kingdom and throughout the world had subscribed to them no less than $69,000,000, of which they had received back in prizes $38,500,000. The expenses and commissions of the sweepstakes involved an expenditure of $16,500,000, and out of the total sum subscribed the Irish hospitals received $14,000,000. As far as Great Britain was concerned, calculation showed that her people had subscribed $47,500,000 and received back in prizes $25,000,000. The commission of sellers of tickets in Great Britain amounted to $8,000,000, and thus there had been transferred from Great Britain to Ireland about $13,750,000. The view has already been expressed that if the British public is willing to supply such a large sum for being allowed to gamble it should be retained for the benefit of the country. The difficulty is the strong feeling against the legalizing of gambling and the obtaining of money for hospitals in this way. However, the sum involved is so large that the home secretary announced in the House of Commons that he was about to appoint a commission to inquire into the subject.

### The Heart and Athletic Training

Professor Vaquez, heart specialist, considered the question as to the effects of intense physical training and of sport activities on the functioning of the heart. He made experiments on the mean arterial pressure, at the special school at Joinville, for the training of athletic instructors in the army, and studied the effects of various forms of exercise on the heart of subjects who had received systematic training. After the 300 meter dash, he measured in many subjects the acceleration of the pulse, the maximum and the mean arterial pressure, and the time required for a return to normal circulatory conditions. He made the following observations:

1. Subjects who have received systematic training have, after a severe test, about the same acceleration of the pulse as subjects who have not had such training. The pulse cannot, therefore, be considered as a sign of aptitude or inaptitude for sport activities. It should be, however, regarded as a suspicious sign if the pulse requires more than five minutes to return to its normal rhythm.

2. The maximum arterial pressure must not exceed 150 mm. of mercury. But one need not consider as a dangerous sign the instability of the pulse after an effort, nor the time required to regain normal frequency. Likewise, one need not be disturbed if the maximum pressure declines for from ten to fifteen minutes after the effort.

3. The mean pressure, which is so important in Vaquez's opinion, must not exceed 110 mm., after the effort, irrespective of the age of the subject. If it is higher than that, radioscopy of the heart should be applied. As for the variations, they must not be more than 30 mm. above normal or from 10 to 20 mm. below normal, whatever the departures from the maximum pressure may be. Undue slowness of the return of the mean pressure to normal is also a bad sign. To sum up, the best characteristic of a good training in subjects with a good constitution is the stability of the mean pressure. Its return to equilibrium after the effort should be immediate, or, in any event, should not require more than two minutes.

### Typhoid Infection from Oysters in Paris

The fear of typhoid still prevents many persons from eating oysters. However, the strict regulations adopted, during the past ten years, with regard to the supervision of the oyster beds of France, and the mode of conservation and the method of marketing these mollusks, appear to have had a good effect. Cases of typhoid derived from oysters are now rarely observed, and, if they do occur, the fault lies with the merchants and not with the management of the oyster beds. Professor Tanon and Mr. Neveu examined, between November, 1931, and March, 1932, 550 samples of oysters taken at random from lots offered for sale in the markets of Paris. In none of the various kinds of oysters examined did they find pathogenic organisms. The shells were, however, contaminated with Bacillus coli. Mr. Tanon recommends avoiding a common source of infection that arises from impurities existing on the outside of the shell. It is advisable to wash and to brush the shell carefully, holding it in pure water, before opening the oyster, in order that possible germs may not be carried within the shell by the knife used in opening the oysters. This precaution is always neglected by the small oyster merchants, and by the restaurants of the populous sections of the city, which often have the habit, in order to keep their baskets of oysters fresh, of placing them in running water at the side of the streets, in spite of administrative orders to the contrary. This water, which is designed only for street cleaning purposes, is always contaminated.

### Decisions of Council of the Federation of Medical Syndicates

Although the ethical order of physicians has not yet been legally established, the council of the Fédération des syndicats médicaux endeavors to assume such a rôle under all circumstances in which it is possible to intervene. The imposition of indirect penalties has become possible owing to the law pertaining to social insurance. This cannot function except as a result of agreements entered into between the regional health insurance societies and the medical syndicates. It is sufficient, therefore, for the syndicate to declare that a given physician, found guilty of misdemeanors affecting the medical profession, may not be permitted to participate in the care of the socially insured, on pain of revocation of the entire agreement, in which case the syndicate would refuse to care for any of the members insured in the health insurance societies. The latter have tacitly accepted this procedure because they consider that this mode of control exercised by the syndicates over the members constitutes a certain guaranty as regards the character of the physician they employ. The recent meeting of the council of the Fédération des syndicats médicaux furnished several examples of this. The council denied to three physicians, who it declared had failed to conduct themselves in accordance with the duties imposed on them by the ethics of their profession, the right to participate in the care to be given to the socially insured. One of them, the director of a clinic, allowed himself to be assisted by a foreigner who not only had no French diploma but had falsely assumed the title of "doctor." A second physician was connected with a chiropractic institute where all he did was to sign the prescriptions of a person who treated all the patients by a peculiar method, although he held no medical diploma. The third physician was found guilty of having, for some undetermined disorder of no significance, during two consecutive months, applied ultraviolet rays and daily subcutaneous injections to a patient. During the past three months, 116 complaints against physicians were addressed to the council, but only 46 of these appeared well founded; the others were manifestly without foundation. As a result of this inquiry, fourteen formal complaints against these confrères were sent to the prefect of the Seine, and in addition fourteen reproofs or warnings were addressed to the physicians in question. Fifteen further cases are being inquired into. The present active control exercised by the council over the members of the federation is sure to have a favorable effect on parliament and will serve to hasten the enactment of the law establishing the ethical order of physicians. The physicians are not obliged to become affiliated with the syndicates, and, in spite of the various advantages that they derive from such affiliation, about one fourth of the physicians of the department of the Seine are not enrolled.

### Creation of a Blood Transfusion Center

Under the influence of a committee of women of the old aristocracy and of the newer, rich bourgeoisie, a permanent service has been created at Paris, in the Hôpital St. Antoine, where persons ready to furnish blood for emergency transfusions are at the disposal of patients at any hour of the day and night. The service has developed from 220 transfusions in 1929 to 779 in 1930 and to 2,038 in 1931, the transfusions having been given in the 178 different services of the 31 hospitals of the Assistance publique. The chief event of the past year has been the creation of a permanent center at the Hôpital St. Antoine. The services of the center are available at any hour of the day or night. The secretary assures prompt service with the aid of a list of immediately available physicians ready to do blood transfusion, and a complete list of blood donors. Furthermore, there is always a donor present for extremely urgent cases. In response to a telephone call, the physician and the donor will arrive in a few minutes in an automobile, which makes it possible to save many a life menaced by a sudden hemorrhage. Also small repeated transfusions are given, and, as Professor Gosset explained in his address delivered at the opening of the center, this movement includes also a center for scientific research. Owing to recent research, immunotransfusion has been used in the treatment of such diseases as typhoid and septicemias.

### Observations on Bromine in the Blood of Mental Patients

Prof. H. Zondek announced in an address delivered before the Berliner Medizinische Gesellschaft that he believes that he has found new and promising ways of treating certain mental diseases. Through skilful combination of chemical, physiologic, anatomic and clinical observations, Zondek became convinced that changes in the bromine content of human blood play a part in cyclic insanity or in manic-depressive conditions. In such cases, he found a considerable diminution of the bromine content of the blood. He successfully treated forty cases of melancholia with small quantities of bromine. This remarkable announcement awakened great interest. Zondek stated that he discovered in the hypophysis a bromine-containing hormone, from which he produced a preparation soluble in water. In experiments on the dog, one can reduce the motor power with this hormone and induce fatigue and apathy. The manner in which this hormone acts on mental patients must be carefully investigated. But even at this stage Zondek feels that he is justified, on the basis of his observations, in advancing a new theory of sleep. In the course of his experiments, he, in collaboration with Arthur Bier, found that with the onset of sleep a shifting of the minute quantities of bromine within certain parts of the brain takes place; for example, in the medulla oblongata, bromine is activated. It develops again in the hypophysis, which with the onset of sleep throws its bromine into the brain fluids. When the sleep is ended and the waking condition is restored, this transference of bromine ceases. The gland begins again to produce and to store up bromine, in order to pour out its hormone again when sleep is renewed. This is certainly a masterful idea. What measure of truth it contains will require long and thorough experiments. Unfortunately, as so often happens, the daily press obtained a report of the lecture and is publishing the statements of Zondek with varying degrees of accuracy, depending on its attitude, and with or without a picture of the speaker. Sensational presentation is not compatible with scientific research.

### Professor Sauerbruch on Traumatic Surgery

At the invitation of the Verein der Berliner Vertrauensärzte, Professor Sauerbruch delivered in his clinic in the Charité Hospital an address on the surgery of accidental injuries and the determination of the degree of disability. At the universities, advances in abdominal and thoracic surgery have forced surgery of the extremities somewhat into the background. A baneful effect on the surgery of accidents is brought about by roentgenologic surgery, because it leads to a neglect of clinical surgery. The trained physician can diagnose every typical luxation or fracture with the aid of his senses. The roentgenogram should serve only purposes of control. As a basis of diagnosis and treatment the roentgenogram easily leads to serious errors, since important secondary injuries, such as paralysis of the nerves, may be overlooked. The physician must be so trained in the clinic that he can diagnose with eye and hand and does not need to rely on the roentgenogram.

For the outcome of accidents, importance attaches to the psychic influence of the physician who first treats the injured person. Sauerbruch's many years of experience in Zurich, where he formerly held the chair of surgery, proved to him that the results following accidental injuries are better in Zurich than in Berlin; not that it is to be assumed that the physicians there are better but that it is better for the injured person to receive a single lump sum in the adjustment of compensation than an annuity. The physician, the patient and the central government have a common interest in freeing social insurance from the influence of the bureaucracy. To concentrate the treatment of accidents in a few special "accident hospitals," Sauerbruch regards as dangerous, because the treatment of accidents loses through such concentration all touch with general surgery. The adjustment of compensation claims is an art and not a bureaucratic affair. It requires an extensive experience with all classes of patients, which can be acquired only in general hospitals. For that reason, the general practitioner should not be eliminated in the treatment of injuries due to accidents, or in the determination of the amount of compensation to which the injured are entitled.

### When Should the Tonsils Be Removed?

The question as to whether diseased tonsils should be removed is a common one; especially patients who suffer frequently from sore throat ask to have the tonsils removed. The relatively simple intervention causes certain eventualities to be forgotten that should not be lost sight of, but which are often ignored owing to the influence of modish tendencies in medicine. Frequently, disorders of remote organs or even general diseases have their origin in the tonsils, which complicates the question considerably. Prof. O. Bruhns, director of the Medizinische Universitäts-Poliklinik in Königsberg, in the *Deutsche medizinische Wochenschrift,* states his opinions on the subject.

The routine removal of the tonsils solely on account of chronic inflammation is contraindicated. This operative intervention is advisable only when the tonsils show a predisposition to disease, which leads to ever recurring attacks, or when internal disorders appear in association with inflammation of the tonsils. In any event, one should wait from four to six weeks with the intervention after disappearance of the acute pathologic manifestations, for then the danger of immediate recurrences is slight. The danger is much greater if one operates immediately or during the acute febrile stage. Then, too, recurrences are more easily avoided with late than with early operations. An early operation should be undertaken only when the disease of internal organs, which originated in the tonsils, is continually flaring up anew or when there is danger that a septic condition may result. It is unquestionably true that complications sometimes arise in association with the removal of tonsils. Pneumonia, sepsis, suppurations of the throat, and still more threatening conditions have been observed. Hence every case must be judged on its own merits.

## ITALY

*(From Our Regular Correspondent)*

March 15, 1932.

### Professor Pianese, the New Academician

Prof. Giuseppe Pianese, professor of anatomy and pathologic histology at the University of Naples, was recently appointed academician of Italy. Pianese was born at Civitanova del Sannio in 1864, and his teaching and scientific career has been confined to the Istituto di anatomia patologica at Naples, where he became professor extraordinarius in 1903 and director in 1917. He is passionately fond of microscopic technic. During his forty years of activity, he has devoted himself to the solution of problems of general biology, normal histology and pathology. In the field of bacteriology may be mentioned his research on Bacillus anthracis. He studied the development of Coccidium oviforme. In the opinion of the Boston Commission, these last researches have thrown light on the question of the biology of the coccidium and on the lesions that this parasite causes in the liver. From 1894 to 1899, Pianese stood almost alone in contending that the so-called cancer bodies were not coccidia but products resulting from changes in the protoplasm, the nucleus and the plasmosome. He demonstrated that blastomycetes do not produce cancer or sarcoma but granuloma. His research found universal confirmation. Pianese was the first to support the infectious nature of Sydenham's chorea, and his name is connected particularly with the discovery that infantile splenic anemia, a disease that is widespread in southern Italy, is produced by a protozoan.

### Nonvenereal Ulcers of the Female Genitalia

Addressing recently the Associazione medica Triestina, Professor Freund discussed the various forms of nonvenereal ulcers of the female genitalia. He considered recent research on certain cutaneous manifestations that not infrequently are associated with ulcus vulvae acutum; for example, erythema nodosum. This research led to the discovery by Samek, of the Clinica Kreibich in Prague, that Bacillus crassus, which is the etiologic agent of ulcus vulvae acutum, is found not only in ulcers of the genitalia but also in cutaneous lesions and even in the circulating blood.

Dr. De Grisogono referred to several tuberculous ulcers: herpes genitalis menstrualis, which may appear other than during the menstrual period; vulvar furunculosis, which, while it is not a pyodermitis peculiar to the external genitalia, nevertheless may assume peculiar characteristics when it occurs on that part of the body. He mentioned ulcers that may appear in the course of such diseases as diphtheria, dysentery and typhoid. Although rare, vulvar diphtheria may appear also in children immune to diphtheria of the throat. Ulcus vulvae acutum of Lipschütz, aside from the presence of B. crassus and its typical location on the inner surface of the labia minora, is characterized by a grayish yellow color at the base, which presents also numerous minute nodules, and which is bordered by undermined and arcuate edges. The inguinal glands, different from all other ulcerative processes, are rarely swollen. Schugt, however, from an accurate study of a case complicated with ulcers of the mouth and tongue, is inclined to question the specificity of B. crassus and thinks that an angioneurotic gangrenous process, with secondary invasion of B. crassus, is involved. As to ulcus vulvae chronicum and its etiology, there are many theories. In addition to syphilis and tuberculosis, constitutional factors have been incriminated; also local circulatory disorders and chronic inflammatory processes. Histologic research reveals only chronic inflammatory conditions and parvicellular infiltrations, sometimes with giant cells of unknown or doubtful origin.

Professor Gacchia remarked that from the case cited by Professor Freund, in which B. crassus was cultivated from ulcers of the female genitalia and from tissue excised from a simultaneous erythema nodosum, one cannot deduce an analogous etiology for the frequent cases of nodular erythemas in persons of the two sexes, since nonvenereal ulcers due to B. crassus are rare and found only in women. Professor Freund replied that the erythema nodosum was observed not only in several cases of ulcus vulvae acutum (Lipschütz) but also in many other infectious disorders, the most peculiar observation being an erythema nodosum containing the Ducrey bacillus following an infection with soft ulcers.

### The Novara Medical Society

The Società di cultura medica of Novara met recently in that city, under the chairmanship of Professor Pietra. Dr. Borrella spoke on subserous cholecystectomy, which he regards as the best method of intervention on the gallbladder. During 1931, in the department of surgery, under the direction of Professor Ferrero, of nineteen cases, seventeen were subjected to intervention by the subserous route, with 85 per cent of favorable results. The method presents advantages over the ordinary transperitoneal method.

### The Inaugural Address of Professor Bastai

Professor Bastai, recently appointed to a chair of pathology at the University of Florence, delivered recently the inaugural lecture of his course, taking as his subject "Anemia Due to Lack of Hormones." He discussed the pathogenesis of pernicious anemia and of chlorosis, considering the latter to be due to ovarian insufficiency and the former to be in relation to changes in endocrine functioning affecting the stomach. The treatment of this subject awakened particular interest, since the pathogenesis of pernicious anemia, as outlined by Professor Bastai, was based on the observation of the efficacy in this disorder of liver and stomach extracts.

### In Honor of Professor Economo

At a recent session of the Associazione medica Triestina, memorial exercises were held in honor of Prof. Costantino Economo. Professor Sai, director of the Istituto provinciale neuropsichiatrico, spoke of the scientific work of Economo, particularly his studies on the cyto-architectonic arrangement of the cortex in man. These studies, which cost Economo thirteen years of continuous research, culminated in the publication of the atlas containing 112 large photographic plates, a unique work in this field. The speaker projected the designs of the five fundamental types of cortex as established by Economo and explained the arrangement in the cortex. Economo brought out the conception of progressive cerebration; namely, of the progressive development of the brain in the phylogenetic series and in the individual species, not only in man but also in dogs and horses. Since the dawn of history there has been a progression in cerebration, as is shown by the development in music through the centuries. The ancient Greeks, though having a high artistic sense, had primitive musical conceptions. Modern music, as understood today, is a recent acquisition of the human cortex.

A study that brought fame to Professor Economo was the discovery, in 1917, of epidemic encephalitis. In the very first cases that came under his observation, he succeeded in pointing out the peculiar clinical, anatomic and biologic characteristics of the disease. The symptomatology of the disease, which is accompanied by peculiar psychic disturbances and disorders of sleep, which range from lethargy to incoercible insomnia, induced Economo to study thoroughly the problems of physiologic sleep and the localization of mental functions. He advanced the theory of the regulatory center of sleep, locating it in the walls of the third ventricle. This theory has the support of clinical, pharmacologic and experimental evidence. The great scientist refused many offers of directorships of neuropsychiatric clinics, preferring to devote all his energy to research. Death overtook Professor Economo suddenly at the age of 56, apparently as the result of thrombosis of the coronary arteries, a few days after the last International Neurologic Congress, held at Berne in 1931, at which he presented a paper.

### Ambulatorium for Diabetic Patients

An ambulatorium for diabetic patients has begun to function in Milan. It will serve as a diagnostic center for the various clinical forms of diabetes, its complications and concomitant diseases, and will constitute a therapeutic guide for the patient. It will also furnish financial aid to the diabetic patient in modest circumstances. In every case, after taking the personal history and the clinical examination, laboratory examinations are carried out: glycemia, basal metabolism, azotemia, tolerance for carbohydrates, and the like. In the matter of diet, two principles that experience has shown to be useful are emphasized: a sparse diet but sufficient for the maintenance of the body weight in relation to height, age and constitution; and avoidance of an excess of proteins, which diminishes the tolerance for carbohydrates and gives rise to the formation of toxic waste material.

## JAPAN

*(From Our Regular Correspondent)*

March 26, 1932.

### Lepers Win over Politics

The largest lepers' sanatorium in Japan is in Kumamoto city. It can accommodate over 500 lepers, men and women, and is under the charge of the local government. In this city Miss Helen Riddel, the celebrated American missionary, who died last month, worked among lepers all through her life. When the principal of this sanatorium was to be dismissed, for political reasons, about 500 lepers undertook to march through that city, March 12. They broke the gate and walked out toward the city, to be halted on the outskirts by police and ex-service men who had been hastily mobilized. There was a deadlock for two hours. The police would not let the lepers march on, and the lepers would not go back. In the end, officials from the prefectural office promised to see that the principal should keep his job. The principal is much loved by the lepers, and they were indignant when told that he was to be dismissed.

### Eight Physicians Obtain Seats in the House

In the general election, February 20, sixteen practitioners ran for the diet, and just half of them were elected, a decrease of five compared with the general election in 1929. The tendency toward a decrease in the number of medical candidates for the diet is inevitable, because the members are obliged to stay in Tokyo during the session for three months, which is inconvenient for medical practitioners. On the other hand, in the election for the prefectural assembly last winter, medical candidates were more successful, increasing their number by about 40 per cent, because it is much more convenient and suitable for them.

### Celebration of Discovery of Tubercle Bacillus

Under the auspices of the Japanese Society for Tuberculosis, the fiftieth anniversary of the discovery of the tubercle bacillus was celebrated, March 24, in Tokyo. The Japanese friends of Koch, knowing that the "Koch-Stiftung" had suffered in the economic crisis in Germany and has nothing left, are anxious to make contributions. The effort has been supported by many philanthropic persons and societies in Japan. Many prominent persons were present on this occasion, including Mr. Inukai, prime mimister, who gave an address. Prince Tokugawa, president of the house of peers, presented the sums raised for the Koch-Stiftung to Dr. Foreztch, the German ambassador to Japan.

### Airplane Ambulance

The Japanese Association of Physicians is planning to construct an airplane ambulance, which will be given to the Imperial Japanese Army. The sum of 100,000 yen needed will be raised soon by contributions from members. Dr. Terashi, the well known army surgeon for aeronautics, is said to be making the plan for the ambulance.

## VIENNA

*(From Our Regular Correspondent)*

March 15, 1932.

### The Crusade Against Alcoholism

At the seventh Oesterreichischer Alcoholgegner-Tag, the chairman of the "abstinent teachers in Austria" explained the importance of the training of youth in the crusade that is being waged against alcoholism. He pointed out that, according to the large majority of psychiatrists, alcoholism is to be regarded as a mental disease. In this disease, as in all diseases, prophylaxis is the most practical and serviceable measure, because young people trained from early youth to oppose and to reject alcoholic beverages constitute the best weapon in the crusade against alcoholism. What is needed is: (*a*) the training of the oncoming generations of teachers to abstain from alcoholic beverages; (*b*) course on the alcohol question and instruction in abstinence for the teachers of all grades of schools; (*c*) migratory teachers to give instruction in temperance; (*d*) elimination of alcoholic beverages from school festivities and outings—also in the schools of higher learning; (*e*) prohibition of alcoholic beverages in all schools and educational institutions; (*f*) winning over of the schools of domestic science and economy for the prohibition movement.

### Sudden Death of Professor Saxl

Dr. Paul Saxl, an eminent authority in internal medicine, died suddenly, a few days ago, during a ski outing, apparently from a heart attack brought on by overexertion, at the age of 52. As a young physician he attracted the attention of Professor von Noorden, who recognized his unusual qualities. Under von Noorden's successor, Professor Wenckebach, he continued at the clinic as first assistant and up to the time of his death was still serving in that capacity. His scientific articles on septic disorders, on the action of metals and on rheumatism served to make his name still further known, but still more his method for the dehydration of the body by means of mercury salts. This is a highly effective method in grave cases of hydrops. The strength of the deceased scientist lay in his stupendous grasp on experimental technic and his unusual powers of observation. His standing was such that he was about to be called to a German university.

### Vacant Chairs at the University of Vienna

There are a number of vacant chairs at the University of Vienna that must be filled before the beginning of the winter semester. A worthy successor to the deceased roentgenologist Holzknecht must be found. It is planned to transform his laboratory, which has functioned heretofore only as a "Zentral-Röntgen-Institut" for the General Hospital, into a research and pedagogic institute connected with the university. No proposals as to a successor have yet been made. Furthermore, new directors for the surgical clinic, the clinic for internal medicine (as Professor Chvostek has resigned), and the gynecologic clinic, must be appointed. Professor Halban was chosen to fill the last mentioned position, but a religiopolitical intrigue has prevented him, thus far, from assuming the duties of the post. At the end of this academic year, two other chairs will become vacant. Professor Hochstätter, of the chair of anatomy, and Dr. Schaffer, professor of histology, will retire in accordance with the law, by reason of having attained the age of 70. These vacant chairs will doubtless all be filled by Austrians. In view of the severe retrenchments necessitated by Austria's financial position, it is not likely that foreign scientists would care to accept a call to Vienna.

### Dr. Gerson's Address on Diet Therapy

At a special meeting of the Vienna Medizinisches Doktoren Kollegium, Dr. Gerson delivered an instructive address on his salt-free diet. By means of roentgenograms he showed that also in cases of pulmonary tuberculosis satisfactory results may be obtained, although many investigators do not share his opinion. The progressive contraction of the lung foci could be plainly shown. Dr. Gerson showed how he succeeded, without injuring the organism, in reducing the daily chlorine elimination to from 1.5 to 2.0 Gm., thus bringing about decisive changes in the organism. His absolutely salt-free diet he was able to apply for years to himself, his family and to more than a thousand persons without noting any disadvantages. The most difficult part of his diet therapy is connected with the protein intake. At the beginning of his research he observed that by drastic reduction of the protein intake many chronic dermatoses (eczemas), and also asthma and migraine, clear up. By adding again animal proteins to the diet they can, however, be brought out again. He uses now the following method: He gives, the first week, no protein at all, then slowly increases the amount up to from six to eight egg yolks. Afterward, he allows the patient a little liver for breakfast, and after from four to six hours another small amount. Later soft cheeses are given, for breakfast, from 3 to 10 Gm., and afternoons, from 10 to 30 Gm. Finally, he goes over to kefir and buttermilk. Potatoes with unsalted butter, and also oatmeal, are allowed. A little later, fish and meat may be given once or twice a week. Dr. Gerson explains his success as due chiefly to the "antiphlogistic" factors that his diet produces. A diet rich in potassium, but salt-free and poor in proteins, acts favorably, according to his experience, in lupus and in the presence of keloids; also in about 45 per cent of the cases of migraine. In about 55 per cent, however, there remains a hypersensitiveness to salt or protein. The action of the new diet therapy in migraine is based, in his opinion, on an overcoming of the spasm of the blood vessels and thus of the central nervous system. In itching eruptions, associated with high blood pressure (angina pectoris), the ingestion of large quantities of vegetable juices is especially important. Also in mental diseases excellent results have been recorded, so that Gerson urged his audience to experiment in that direction, stating that he would give written advice on the subject to any one requesting it. During the discussion that followed Dr. Gerson's address, Professor von Noorden (who now resides in Vienna) stated that, in his opinion, limitation of sodium chloride intake suffices (without elimination of protein) to secure therapeutic results. Professor Neumann pointed out that, in spite of the pulmonary cases in which cures had been effected by Gerson's diet, new foci sometimes appeared during the dietary treatment, so that the treatment could hardly be regarded as an absolutely reliable therapeutic method.

---

## *Marriages*

William S. Dininger, Winchester, Ind., to Miss Lela Green of Cincinnati, at Hamilton, Ohio, April 25.

Francis J. Quinlan, New York, to Mrs. Elizabeth Maurer at Kitchawan, N. Y., April 17.

Cecil E. Johnson to Miss Mary May, both of Rensselaer, Ind., at Hammond, April 27.

Robert Reagles, Arlington, Wis., to Miss Nellie M. Chase, April 21.

## *Deaths*

**John Alden Lichty** ⊕ Clifton Springs, N. Y.; University of Pennsylvania School of Medicine, Philadelphia, 1893; member of the American Gastro-Enterological Association, American College of Physicians, American Climatological and Clinical Association and the American Psychiatric Association; past president of the Ontario County Medical Society; at one time associate professor of medicine, University of Pittsburgh School of Medicine; for many years on the staffs of the Columbia Hospital, Wilkinsburg, and the Mercy Hospital, Pittsburgh; since 1923 superintendent of the Clifton Springs Sanitarium and Clinic; trustee of the Mount Union College, Alliance, Ohio, and the Colgate-Rochester Divinity School, Rochester; aged 66; died, May 2.

**Walter John Kremer** ⊕ Minneapolis; University of Minnesota Medical School, Minneapolis, 1911; fellow of the American College of Surgeons; formerly instructor in urology at his alma mater; served during the World War; associate urologist to the Minneapolis General Hospital and on the urological staff of the Asbury, St. Mary's and St. Barnabas hospitals; consulting urologist to the U. S. Veterans' Bureau; aged 53; died, April 2, in the Veterans' Administration Hospital, Fort Snelling, of heart disease.

**Merlin Chauncey Johnston** ⊕ Aberdeen, S. D.; Rush Medical College, Chicago, 1896; formerly assistant professor of pathology, Minneapolis College of Physicians and Surgeons; councilor of the first district of the South Dakota State Medical Association; city and county health officer; past president of the city board of health; aged 59; on the staff of St. Luke's Hospital, where he died, April 2, of valvular heart disease and embolism.

**Otto Tiger Freer** ⊕ Chicago; Rush Medical College, Chicago, 1879; secretary of the Section on Laryngology and Otology, American Medical Association, 1903-1905, chairman, 1905-1906, and delegate, 1907-1908; formerly associate professor of laryngology and otology at his alma mater; aged 74; for many years on the staff of the Henrotin Hospital, where he died, April 21, of heart disease, chronic myocarditis and paralytic ileus.

**Charles Lybrand Bonifield** ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1886; professor of gynecology, University of Cincinnati College of Medicine; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, and the Southern Surgical Association; on the staffs of the Cincinnati General Hospital and the Christ Hospital; aged 69; died, April 23, of cerebral hemorrhage.

**Frank Spencer Pomeroy,** Chardon, Ohio; University of Wooster Medical Department, Cleveland, 1881; University of the City of New York Medical Department, 1885; member of the Ohio State Medical Association; past president of the Geauga County Medical Society; for many years county coroner; aged 76; died, April 12, of pneumonia and cerebral hemorrhage.

**Marc Ray Hughes,** St. Louis; Barnes Medical College, St. Louis, 1898; member of the Missouri State Medical Association; at one time professor of nervous diseases and psychology at his alma mater; formerly member of the state board of health; served during the World War; aged 54; died, April 5, in the Evangelical Home and Deaconess Hospital, of pneumonia.

**William G. Kemper** ⊕ Manitowoc, Wis.; Rush Medical College, Chicago, 1882; past president of the Manitowoc County Medical Society; for many years county coroner; formerly mayor and city health officer of Manitowoc; aged 72; on the staff of the Holy Family Hospital, where he died, April 8, of septicemia.

**John Ernest Watson,** Anderson, S. C.; University of Georgia Medical Department, Augusta, 1899; member of the South Carolina Medical Association; past president of the Anderson County Medical Society; on the staff of the Anderson County Hospital; aged 54; died, April 13, of heart disease.

**Jay B. Brewer,** Jefferson, Wis.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1893; member of the state board of medical examiners; for ten years mayor of Jefferson; aged 72; died, April 13, in a hospital at Milwaukee, of hypostatic pneumonia, myocarditis and cerebral thrombosis.

**Searle Bewley Gillespie,** Johnson City, Tenn.; University of Tennessee Medical Department, Nashville, 1905; member of the Tennessee State Medical Association; on the staff of the Jones Eye, Ear, Nose and Throat Hospital; aged 47; died suddenly, April 7, of acute dilatation of the heart.

**Benjamin Franklin Shuttleworth** ⊕ Clarksburg, W. Va.; Jefferson Medical College of Philadelphia, 1905; formerly member of the Public Health Council; fellow of the American College of Physicians; on the staff of St. Mary's Hospital; aged 54; died suddenly, March 31, of heart disease.

**Eugene A. Crouse**, Grundy Center, Iowa; University of Pennsylvania School of Medicine, Philadelphia, 1870; member of the Iowa State Medical Society; past president of the Grundy County Medical Society; aged 85; died suddenly, April 8, of cerebral hemorrhage.

**Jefferson D. Kiser** ⊕ Bartlesville, Okla.; Kentucky School of Medicine, Louisville, 1894; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Washington County Memorial Hospital; aged 63; died, April 14, of heart disease.

**John William Landgraf** ⊕ Seneca, Ill.; Northwestern University Medical School, Chicago, 1909; aged 45; died, April 18, in the Ryburn-King Hospital, Ottawa, of injuries received when his car, which he was having greased, overturned on him from a hydraulic lift.

**William E. Connor** ⊕ Cumby, Texas; University of Louisville (Ky.) School of Medicine, 1894; past president of the Hopkins County Medical Society; bank president; aged 59; died, April 7, in a hospital at Dallas, of heart disease, following an operation.

**Earl Lester Hall**, Princeton, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1902; aged 54; died, April 8, in the Veterans' Administration Hospital, Fort Snelling, of bronchopneumonia.

**Martin Van Buren Dunham**, Greenfield Hill, Conn.; Harvard University Medical School, Boston, 1867; member of the Connecticut State Medical Society; Civil War veteran; aged 91; was found dead in bed, April 21, of heart disease.

**John William Hopkins**, Maryville, Mo.; Rush Medical College, Chicago, 1931; member of the faculty of the Northwest Missouri State Teachers' College; aged 28; died, April 8, in a local hospital, of a self-inflicted bullet wound.

**Cyrus Monroe Easton**, Davenport, Neb.; Rush Medical College, Chicago, 1872; formerly member of the board of education of Hebron; aged 89; died, February 21, of cerebral hemorrhage while on a visit in Oklahoma.

**George T. Hannah**, Toledo, Ohio; Ohio Medical University, Columbus, 1906; member of the Ohio State Medical Association; aged 51; died, April 15, in the Mercy Hospital of cholelithiasis and intestinal obstruction.

**Jacob T. Cramer**, Muskegon, Mich.; Rush Medical College, Chicago, 1904; member of the Michigan State Medical Society; formerly city and county physician; aged 50; died, April 5, of cerebral hemorrhage.

**Oliver R. Eylar**, Waverly, Ohio; Starling Medical College, Columbus, 1900; member of the Ohio State Medical Association; county health officer; aged 71; died, April 17, in Circleville, of cerebral hemorrhage.

**Henry Schell Kimmell**, Somerset, Pa.; Jefferson Medical College of Philadelphia, 1880; for many years county coroner; formerly member of the school board; aged 74; died suddenly, March 31, of heart disease.

**Elliott R. Hatfield**, Charleston, W. Va.; Hospital College of Medicine, Louisville, Ky., 1898; member of the West Virginia State Medical Association; aged 59; was found dead, April 20, of heart disease.

**Partee Harris Mangrem**, Columbia, Tenn.; University of Tennessee Medical Department, Nashville, 1894; member of the Tennessee State Medical Association; aged 65; died, April 12, of angina pectoris.

**Charles Leopold Barewald**, Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1891; formerly mayor of Davenport; aged 61; died suddenly, April 14, of heart disease.

**William R. Reves** ⊕ Alma, Ark.; University of Tennessee Medical Department, Nashville, Tenn., 1892; aged 72; died, February 7, in Fort Smith, of angina pectoris, cholelithiasis and myocarditis.

**Robert H. Wicker**, Rome, Ga.; University of Georgia Medical Department, Augusta, 1878; member of the Medical Association of the State of Georgia; aged 74; died, April 10, of pneumonia.

**Franklin Henry Staley**, Vienna, S. D.; Rush Medical College, Chicago, 1886; member of the South Dakota State Medical Association; aged 72; died, April 2, of carcinoma of the stomach.

**C. K. Tillison**, Ramona, Okla.; Northwestern Medical College, St. Joseph, Mo., 1893; member of the Oklahoma State Medical Association; aged 62; died, April 13, of cerebral hemorrhage.

**Albert Lee Yocom**, Chariton, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1886; city health officer; aged 76; died, in March, at the Yocom Hospital, following an operation.

**Elmer F. Brown** ⊕ Groveton, N. H.; Baltimore Medical College, 1897; aged 63; died, April 10, in the Lancaster (N. H.) Hospital, of strangulated ventral hernia and paralytic ileus.

**James Claude Fortenberry**, Zavalla, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907); aged 53; died, April 6, in a sanatorium at San Antonio.

**Ezra Dwight Chase** ⊕ Chicago; Northwestern University Medical School, Chicago, 1905; on the staff of the Garfield Park Hospital; aged 50; died, May 2, of chronic myocarditis.

**Louis A. Mehler**, Louisville, Ky.; University of Louisville School of Medicine, 1908; member of the Kentucky State Medical Association; aged 60; died, March 30, of heart block.

**Joseph William Pecony** ⊕ Denver; John A. Creighton Medical College, Omaha, 1914; aged 43; was found dead, April 7, of strychnine and morphine poisoning, self-administered.

**Carlton Monroe McGuire**, Humeston, Iowa; Rush Medical College, Chicago, 1891; formerly coroner of Huerfano County, Colo.; aged 69; died, March 27, of cerebral hemorrhage.

**Joseph Ernest Maunders**, Detroit; Detroit College of Medicine, 1911; member of the Michigan State Medical Society; aged 52; died suddenly, April 13, of cerebral hemorrhage.

**John C. Hayward** ⊕ Marshfield, Wis.; Chicago Medical College, 1882; past president of the Wood County Medical Society; aged 74; died, April 11, of chronic myocarditis.

**David Napoleon Haydon**, Mount Dora, N. M. (licensed, Indiana, 1897); also a druggist; aged 78; died, in February, at a hospital in Las Vegas, of cerebral hemorrhage.

**Louis Henry Fleck** ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1896; on the staff of St. Catherine's Hospital; aged 56; died, April 18, of heart disease.

**Benjamin W. Tilford**, Martinsville, Ind.; Butler University Medical Department, Indianapolis, 1881; formerly a druggist; aged 72; died, in April, of heart disease.

**George M. Galley**, Cincinnati; Medical College of Ohio, Cincinnati, 1905; aged 60; died, April 10, in St. Mary's Hospital, of acute dilatation of the heart.

**Merrit B. Hook**, Denver; Rush Medical College, Chicago, 1900; member of the Colorado State Medical Society; aged 57; died, April 12, of heart disease.

**Carol Skinner Cole** ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1922; aged 43; was killed, March 21, in an airplane accident.

**John William Dobson**, Moweaqua, Ill.; University of Michigan Medical School, Ann Arbor, 1892; aged 67; died, April 15, of coronary thrombosis.

**Burr Hamilton Emerson**, Stockton, Mo.; Kansas City Medical College, 1899; aged 56; died, April 10, of injuries received when he fell downstairs.

**William Edward Reller**, Twin Falls, Idaho; Hahnemann Medical College and Hospital, Chicago, 1885; aged 68; died, March 27, of heart disease.

**John B. Wear**, Poteau, Okla.; University of Arkansas School of Medicine, Little Rock, 1888; aged 76; died, March 10, of cerebral hemorrhage.

**Joseph Cooper Densten**, Scranton, Pa. (licensed, Pennsylvania, 1869); aged 83; died, April 8, of pneumonia, following burns received in a fire.

**Hermon C. Hill**, Benton Harbor, Mich.; Rush Medical College, Chicago, 1892; aged 65; died, April 17, of a self-inflicted bullet wound.

**John Anderson Burris**, Riverside, Ky.; University of Louisville School of Medicine, 1907; aged 54; died, April 17, of cardiac asthma.

**Mary E. Barnes Ray**, Ponca City, Okla.; Homeopathic Hospital College, Cleveland, 1887; aged 68; died, April 12, of heart disease.

**Brock E. Brush** ⊕ Port Huron, Mich.; Detroit College of Medicine, 1896; aged 66; was found dead, April 15, of cerebral hemorrhage.

**Thomas J. Walsh**, Chicago; Rush Medical College, Chicago, 1896; aged 55; died, April 21, of coronary thrombosis.

## VEIN LIGATION IN THE TREATMENT OF ARTERIOSCLEROTIC AND DIABETIC GANGRENE

*To the Editor:*—In THE JOURNAL, March 12, Herman E. Pearse, Jr., gives a comprehensive discussion of vein ligations in the treatment of arteriosclerotic and diabetic gangrene. Since the publication of my first case (THE JOURNAL, April 13, 1929, p. 1264), vein ligation was performed in two patients. The indications in all three cases were the same: an impending gangrene, but no break in the continuity of the skin, absence of peripheral pulses below the popliteal artery, excruciating pain both after exercise and at rest. These patients would more or less fit into group 3 of Dr. Pearse's classification.

The immediate results (two popliteal veins and one femoral vein were ligated) were very gratifying, in that there was relief from pain and marked increase in surface temperature. Nevertheless, all three cases came to amputation within six months. Edema, which according to Dr. Pearse occurred only once in thirty cases, was present in all three patients. It did not come on immediately after the operation or when the patient first got out of bed, but weeks or months later. Thus, the first patient, when examined four months after the operation, was still free from edema. The appearance and intensity of the edema due to vein ligation depends on the extension of the clot into tributaries and not so much on the venous obstruction at one point (Zimmermann and de Takáts, *Arch. Surg.* **23**:937-953 [Dec.] 1931). It is just possible that such vein ligations favor the production of massive thromboses that may occur with arterial occlusions. In the first case, in which I performed amputation six months later, there was an extensive thrombosis distal to the ligature extending into smaller tributaries. The other two patients had amputation done elsewhere.

While the immediate relief in these cases is obvious, the late results have not encouraged me to continue this procedure. Conservative treatment in this group has arrested the disease in at least as large a proportion (60 per cent) as vein ligation in Dr. Pearse's series.

GÉZA DE TAKÁTS, M.D., Chicago.

## THALLIUM PREPARATIONS DANGEROUS TO WILD BIRDS AND ANIMALS

*To the Editor:*—So much has appeared in THE JOURNAL during the past year regarding thallium poisoning, principally from the use of depilatory creams, that it may be of interest to note that probably the largest users of thallium are the state and federal governments in an effort to control wild rodents.

In California, during 1928, 7,739,070 acres of land was treated for ground squirrels. More than 2,000,000 pounds of poisoned grain was used, of which 602,728 pounds was thallium treated (Linsdale, Jean M.: Facts Concerning the Use of Thallium in California to Poison Rodents—Its Destructiveness to Game Birds, Song Birds and Other Valuable Wild Life, *Condor* **33**:95 [May] 1931). The amount of thallium in this large amount of grain is not stated but it must be considerable. The other poison used is strychnine.

As may be inferred from the title of Linsdale's article, naturalists are gravely concerned over this wholesale distribution of poison, as many other forms of wild life besides the ground squirrels apparently are killed. Joseph Grinnell in an editorial in the *Condor* (**33**:131) makes the statement that "in the last four years not less than 50 *million* animals *other than* ground squirrels have been killed in California through these operations." Most of the members of national societies interested in birds and mammals (American Ornithologists' Union, National Association of Audubon Societies for the Protection of Wild Birds and Animals, American Society of Mammalogists) are rather strongly opposed to this wholesale use of poisons and view with alarm further destruction of our fast vanishing wild life.

M. W. LYON, JR., M.D., South Bend, Ind.

## HYSTERECTOMY AND PANHYSTERECTOMY

*To the Editor:*—THE JOURNAL for April 2 contains a specimen of faulty orthography that it seems to me should not be allowed to go entirely unchallenged. In the article on "Chorionepithelioma of the Uterus," by Lackner and Leventhal, on page 1138, first column, ninth line from the top, the statement is made that "a panhysterectomy was rapidly performed." On page 1139, beginning at the fourteenth line, the following occurs: "When the vaginal metastases occurred, the question arose as to whether the cervix should be removed. We had not performed a total hysterectomy . . ."

Now, to my mind, the word "panhysterectomy" means one thing, and only one thing, the complete removal of the uterus, body and cervix, and has nothing to do with the adnexa or other structures. Used thus, properly, the two statements are of course incompatible. Unfortunately, I find that among nurses and others there is an unfortunate tendency to misuse the term "panhysterectomy" to refer to the removal of the corpus uteri with the adnexa, but it seems strange to find it thus totally misapplied in a scientific article appearing in a publication of the standing of THE JOURNAL.

GEORGE W. OUTERBRIDGE, M.D., Philadelphia.

### TEMPERATURE OF THE LIVER

*To the Editor:*—For some time I have been carrying on clinical researches in the thermic treatment of the liver, produced by means of high frequency currents. 1. I am anxious to know whether the temperature of the liver itself or the temperature of the blood leaving the liver is higher than that of the other tissues, the brain perhaps, excepted. I am aware of the metabolic rise that takes place during the digestive phase of the liver. I know that Dr. Crile believes that the tissues of the brain and liver are of higher temperature. 2. Do you know of any experiments or investigations along this line that would give me the information I desire? 3. Is the circulation in the liver of such volume that practically the entire blood of the body would pass through the hepatic circulation in a few minutes? Please omit name.

M.D., Kentucky.

ANSWER.—1. The liver is by no means the hottest organ of the body. Ito (*Ztschr. f. Biol.* **38,** 1899) found the duodenum the hottest organ—higher than the liver—in a large series of readings on various organs (both in normal animals and in animals after heat puncture). It is generally conceded that the liver and the skeletal musculature contribute most of the heat of the body. The liver, of all organs, is the first to experience an increased temperature when hibernating animals awaken. The liver is hotter than aortic blood. However, into the liver there is poured blood from various internal organs—a venous blood not subjected to cooling before reaching the liver. What is more significant, blood in the hepatic veins has a higher temperature than the blood reaching the liver through the portal vein, indicating an active heat production by the liver. Denervation (or enervation) of the liver results in a marked diminution in the ability of the animal to regulate body temperature in the absence of shivering (destruction of the plexus hepaticum in dogs, described by Plaut: *Ztschr. f. Biol.* **76,** *1922*).

2. Cloetta and Waser (*Arch. f. exper. Path. u. Pharmakol.* **79,** 1915) made extensive thermo-electric measurements of various parts of the body during the action of intravenously *injected* epinephrine.

3. The experiments of K. Hürthle on two dogs and two rats demonstrate the significant capacity changes which the liver is

capable of showing. This organ, perfused with blood through the portal vein under a pressure of from 20 to 50 cm. of water, can hold from 15 to 50 per cent of its weight in blood, which amounts to a fifth or a sixth of the total blood of the animal, exclusive of the blood coming to the liver by way of the hepatic artery (*Handb. d. normal. u. path. Physiol.* **7**:1486, 1927). On the basis of observations made independently by three different observers, the rate of blood flow through the liver amounts to from 85 to 100 cc. per hundred grams of liver a minute. Only Burton-Opitz measured directly the rate of flow through the hepatic artery and portal vein (*Quart. J. Exper. Physiol.* **4**:113, 1911). From this it would appear that the entire blood of the body can theoretically pass through the liver in a short time even if not "in a few minutes."

## BLOOD GROUPS AND GROUP TESTING

*To the Editor:*—Will you please give me information on the following: Is the blood of children always of the same group as that of the father? Suppose the mother belongs to a different group from the father, will the children still have the same group as the father? If not, how does it work out? How much blood is needed for group testing? What is the best vehicle: Test tube, clot on slide or smear? Please omit name.

M.D , New York.

Answer.—The blood of children is not always of the same group as that of the father. Ottenberg and Beres, who have been much interested in the question of inheritance of blood groups, write as follows in Jordan and Falk's "Newer Knowledge of Bacteriology and Immunology," pages 911 and 912: "It is clear that not the groups as such are inherited but the presence or absence of the agglutinogens A and B (Landsteiner International Classification). Von Dungern and Hirschfeld in 1910 observed that: (1) A or B never occurs in the red cells of a child if not present in one of the parents. (2) When one of these substances is present in both parents it occurs in most of the children. (3) When only one parent has one of these particular substances some of the children inherit it. (4) When a particular substance is absent from both parents no child ever has it." Although a number of workers have repeatedly confirmed the statements of Ottenberg and Beres, the subject is still one of controversy.

Although the determination of the blood group can be made with only a few drops of red blood cells, it is preferable to have at least 0.5 cc. of whole blood and 0.25 cc. of blood in sodium citrate (2 per cent) or in some other anticoagulant.

It is convenient to have a test tube for the whole blood and another test tube containing the anticoagulant for the red blood cells.

## UNDULANT FEVER

*To the Editor:*—I have under treatment a case of undulant fever. The patient is a married woman, aged 21. She has been acutely ill since Oct. 17, 1931, when I first saw her, and has been hospitalized since that time. It took several weeks to make a definite diagnosis, but a positive blood culture for Brucella abortus, bovine type, was obtained the latter part of November. Positive cultures have never been obtained from the stools or urine. Early in December she had very acute gallbladder symptoms; these did not abate and cholecystectomy was done. This was followed by a two weeks' remission of fever, but the temperature went up again. Early in January she had acute symptoms referable to the left ovary (the right ovary had been removed several years before). Left oophorectomy was done and smears from the ovary showed the organisms in great abundance. This operation was also followed by a ten day remission of fever, but since then the temperature has ranged from 101 to 105 F. every day. The treatment at present is almost entirely symptomatic. She is getting ultraviolet radiation daily. I have given various tonics, hematinics and protein injections. I also tried methyl violet as recommended in an article by Leavell, Poston and Amoss in The Journal, Sept. 20, 1930, but with no benefit. In spite of the long illness, her general condition appears good. Hemoglobin is 79 at this time. Recent textbooks do not offer anything helpful, nor have I found much help in the literature. It seems that there is no vaccine or serum available and intravenous medication is not advised. Can you offer any suggestions? I will watch The Journal with interest. Please omit name.

M.D., Virginia.

Answer.—Several observers (Simpson, Harbinson, Angle, Helwig, Bassett-Smith, Auricchio, Cumston, de Finis, Giuffrè, Khaled and Prausnitz in the articles listed below) have reported favorable therapeutic results with specific Brucella melitensis (abortus) vaccine therapy. The intravenous administration of mercurochrome-220 soluble or acriflavine hydrochloride has been advocated by a few physicians, while others have reported that such therapy was ineffective. The transfusion of whole blood of a person who has made a satisfactory recovery from undulant fever has been employed in a few instances with apparently satisfactory results. Two Brucella melitensis variety abortus vaccines have been accepted for New and Nonofficial Remedies (The Journal, February 6, p. 480, and May 14, p. 1744).

## PULMONARY ANTHRAX

*To the Editor:*—A white girl, aged 18, with pulmonary anthrax, has been under my care since Sept. 14, 1931. Her temperature continues to range between 97 and 103 F., usually between 97 and 100.3. She has chills occasionally. She has had 650 cc. of antianthrax serum intravenously, the last injection, October 6, causing an anaphylactic reaction. The right lung had to be drained seven times between September and November but has not needed attention since. The constant fever and occasional chill with a higher fever are very discouraging and it is thought that another course of serum might be beneficial. Would this be possible and if so how would one go about desensitizing the patient? She is getting salicylates, iodides and sodium cacodylate. Would you recommend any other course of treatment? Please omit name.

M.D., Nebraska.

Answer.—No special recommendations for treatment will be made, but it may be suggested that special efforts be put forth to determine whether any secondary infection has developed. It is possible that the case no longer is one of pure anthrax infection. It is difficult to prescribe exactly how desensitization should be carried out. Assuming that the antianthrax serum to be used has been developed in the horse, desensitization would better be begun with not more than 0.01 cc. of the serum subcutaneously and if no symptoms appear this dose might be doubled every half hour or so until 1 cc. has been given; then in another half hour 0.1 cc. should be given intravenously and this doubled every fifteen to twenty minutes until the required amount of serum has been injected. The serum given intravenously should be diluted with an equal amount of physiologic solution of sodium chloride and injected as slowly as possible. Dyspnea, cyanosis, coughing, restlessness, swelling of the face, erythema and urticaria are the symptoms to be watched for. Needless to say, before desensitization is begun, preparation should be made for the prompt administration of epinephrine if necessary. The symptoms may come on immediately on introduction of the serum, or soon after.

## VERTIGO AND INTERNAL EAR

*To the Editor.*—A man is struck on the point of the jaw and develops dizziness, which lasts for more than three years. Tests show impaired hearing on the left side of nerve deafness type and impaired labyrinthine function, as evidenced by a response to a caloric test on the right side after thirty seconds' douching, and no response on the left side after three minutes' douching. As the blow seemed hardly violent enough to produce such severe symptoms, some other possible cause is being looked for. Do you think that a focus of infection in the teeth could explain his affliction? Disregarding this accident, would you consider that a vertigo which improved after a generous dosage of sodium salicylate was most likely due to toxins of bacterial origin? In other words, would sodium salicylate dosage be a therapeutic test to determine whether vertigo was due to a focus of infection? Please omit name.

M.D., New York.

Answer.—A blow on the head may cause severe injury to the inner ear, so that impairment of the inner ear with disturbance of the vestibular function may result. Everything else being equal, the cochlea, or hearing portion, is the more likely to be damaged and, if acute hemorrhage occurs, both the hearing and the vestibular mechanism may entirely lose their function. This is what probably happened in the case cited. It is doubtful whether any infection of the teeth could suddenly produce such a lesion. In some instances an apical abscess may produce a toxemia, which in turn causes a temporary change in the cochlear function with tinnitus or noises in the head or, on the other hand, disturbance of the vestibular mechanism may occur with resulting vertigo. After the removal of the infected tooth, these symptoms usually subside. It is doubtful whether sodium salicylate will eliminate a vertigo or that it could be used as a therapeutic test when the vertigo is due to a focus of infection.

### PARESIS OF ORBICULARIS PALPEBRAE MUSCLE THROUGH INJECTION OF PROCAINE

*To the Editor:*—A dentist recites an experience in which the injection of a few cubic centimeters of 1 per cent procaine into the lingual canal caused a marked dilatation of the palpebral fissure of the left eye. This occurred five minutes after injection. He kept the patient in the office thirty-five minutes, at the end of which time the fissure returned to normal. There were no other signs or symptoms of shock or idiosyncrasy or complaints that would make one think it was due to the type of fluid injected. I would be pleased to receive an explanation of this. Mac. D. Campbell, M.D., Detroit.

Answer.—The widening of the palpebral fissure was undoubtedly due to a temporary paresis of the orbicularis palpebrae muscle by nerve block by the procaine, with subsequent drooping of the lower lid from gravity. The lower part of the muscle is innervated by the zygomatic branch of the facial nerve, which ordinarily is given off immediately after emergence of the nerve from the stylomastoid foramen. But in some instances the zygomatic or second branch of the facial nerve accompanies the cervicofacial or third branch for a short distance along its course, and probably in the case referred to the somewhat abnormally located second branch was blocked by procaine that must have escaped into the tissues around the "lingual canal." Any drug used for nerve blocking would have produced the same results under identical circumstances.

### "GLUCOSIN"

*To the Editor:*—Please advise me as to whether the product "Glucosin" is a recognized one. One of my patients, with a blood sugar of 350 mg., has been promised a "sure cure" in six months with this product by this Dr. A. Casagrande, the distributor of the product. Is Dr. Casagrande a doctor of proper standing and qualified to practice medicine in this country? M. F. Lehman, M.D., Little Neck, L. I.

Answer.—The advertising circular referred to is a typical example of pseudoscientific polyglandular therapeusis. The name of the promoter is not a familiar one to those in authority in the field of diabetes in America, and it is doubtful whether his Italian colleagues regard him as an authority. It should be evident that any one promising a "sure cure" of diabetes in six months must be a charlatan.

### BORIC ACID HARMFUL INTERNALLY

*To the Editor:*—One of my patients is interested in knowing whether boric acid taken in pill or capsule form, 20 grains daily, for reducing purposes would be harmful. Please omit name. M.D., Wisconsin.

Answer.—Boric acid, 1.3 Gm. (20 grains), taken internally for reducing purposes, would be decidedly harmful. A number of deaths from boric acid have been reported. A few years ago The Journal discussed editorially the deaths of six infants in a hospital resulting from the nurses having inadvertently mistaken a bottle containing boric acid for one containing water (The Journal, March 12, 1927, p. 841).

### OBSESSION FOR EGGS IN DIET

*To the Editor:*—I have had under observation a man who suffers from cerebral arteriosclerosis and who has an obsession for eggs, eating from six to eight daily. As a result of this he has had a foul sulphide breath, which I have been unable to eliminate. The family of my patient can hardly put up with this odor and the patient refuses to eat anything except milk and eggs. He is not troubled with constipation. He takes acidophilus milk twice a day, but this had not helped him. The teeth and throat are normal. Please advise me whether you know what can benefit this man. Kindly omit name. M.D., New York.

Answer.—It is difficult to see what can benefit the patient if he persists in limiting his food intake to milk and eggs. This procedure results not only in the excess of eggs but naturally produces a marked disturbance of the nutritional balance. This, of course, cannot be rectified except by an entire change in the diet. However, it might be of some avail to add milk sugar to his milk so that there is an excess of available lactose in the gastro-intestinal canal. Also, some form of alkali, such as sodium bicarbonate or magnesia magma, might be of help. These suggestions are, of course, merely palliative.

## COMING EXAMINATIONS

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

Arizona: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave., Phoenix.

California: *Reciprocity.* Los Angeles and San Francisco, June 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Basic Science.* New Haven, June 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

Delaware: Wilmington, June 14-16. Sec., Dr. Harold L. Springer, 1013 Washington St., Wilmington.

District of Columbia: *Basic Science.* Washington, June 29-30. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Florida: Tampa, June 13-14. Sec., Dr. W. M. Rowlett, 812 Citizens Bank Bldg., Tampa.

Georgia: Atlanta, June 15-16. Joint Sec., Mr. R. C. Coleman, 111 State Capitol Bldg., Atlanta.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Indiana: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

Iowa: Iowa City, June 7-9. Dir., Mr. H. W. Grefe, Capitol Building, Des Moines.

Kansas: Kansas City, June 21-22. Sec., Dr. C. H. Ewing, Larned.

Kentucky: Louisville, June 8-10. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.

Louisiana: New Orleans, June 9-11. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Maryland: *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore. *Regular.* Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

Michigan: Ann Arbor and Detroit, June 7-9. Sec., Dr. Nelson McLaughlin, 1010 Maccabee Bldg., Detroit.

Minnesota: *Basic Science.* Minneapolis, June 7-8. Sec., Dr. J. Charmley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Regular.* Minneapolis, June 21-23. Sec., Dr. E. J. Engberg, 524 Lowry Medical Arts Bldg., St. Paul.

Missouri: St. Louis, June 14-16. Sec., Dr. James Stewart, Capitol Bldg., Jefferson City.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

Nebraska: *Regular.* Omaha, June 9-11. Dir., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315, State Education Bldg., Albany.

North Carolina: Raleigh, June 20. Sec., Dr. John W. MacConnell, Davidson.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, June 7-10. Sec., Dr. H. M. Platter, 85 E. Gay St., Columbus.

Oklahoma: Oklahoma City, June 8-10. Sec., Dr. J. M. Byrum, Shawnee.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Texas: Marlin, June 21-23. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Vermont: Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 15-18. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

Wyoming: Cheyenne, June 6. Sec., Dr. W. H. Hassed, Capitol Bldg., Cheyenne.

## Washington January Report

Mr. George L. Berger, assistant director, Washington Department of Licenses, reports the written examination held at Seattle, Jan. 18-19, 1932. The examination covered 8 subjects. A grade of 60 per cent was required in each subject. Twenty-one candidates were examined, all of whom passed. Seven physicians were licensed by reciprocity with other states and 2 physicians were licensed by endorsement. The following colleges were represented:

PASSED

| College | Year Grad. | Per Cent |
|---|---|---|

† The M.D. degrees and certificates are being withheld pending completion of internship.

## North Dakota January Report

Dr. G. M. Williamson, secretary, North Dakota State Board of Medical Examiners, reports the oral, written and practical examination held at Grand Forks, Jan. 5-8, 1932. The examination covered 13 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. One physician was licensed by reciprocity and 1 by endorsement. The following colleges were represented:

| College — PASSED | Year Grad. | Per Cent |
|---|---|---|
| Northwestern University Medical School | (1929) 83, (1931) | 84, 84.3 |

# *Book Notices*

**Laboratory Technique.** By R. B. H. Gradwohl, M.D., Director, Gradwohl School of Laboratory Technique. With the collaboration of I. E. Gradwohl, B.A., Associate Director, and A. S. Gradwohl, Assistant Director, Gradwohl School of Laboratory Technique, St. Louis, Mo. Cloth. Price, $8. Pp. 462, with 148 illustrations. St. Louis: Gradwohl School of Laboratory Technique, 1932.

The authors have compiled a manual of laboratory tests used in medical and surgical diagnoses. The tests are described clearly and concisely, and the directions are explicit. The chapters of the book cover the usual range of subjects discussed in the more comprehensive books on laboratory methods, with added features of chapters on photomicrography, mycology and parasitology. The methods given in the last mentioned chapter are those in vogue at the Hamburg Institute of Tropical Medicine. In the chapter on hematology, special stress is given to the methods and interpretations of blood examination sponsored by Schilling. The illustrations are grouped in the back of the book as a concise atlas of common microscopic subjects encountered in routine laboratory examinations. Instead of the conventional diagrammatic sketches, the authors present photomicrographs in an effort to picture the natural appearance under a microscope. The purpose of the authors is excellent, but unfortunately the ideal has not been accomplished in the pictures of some of the leukocytes where nuclear detail is of paramount importance in successful identification. A chapter on basal metabolism is of great value, containing explicit directions and various tables on different standards and data sheets. Bacteriology and serology are unusually complete for a manual of laboratory technic. The bulk of the book might have been sacrificed for one of more convenient size, especially where methods are presented and it is important to follow the text closely. The authors have made no attempt to offer any interpretative conclusions but desire merely to develop a working manual of standard methods now in use. While they present a comprehensive treatise of medical laboratory methods intended for the profession, the book will serve those best who are actually engaged in laboratory work.

**Die theoretischen Grundlagen und die praktische Verwendbarkeit der gerichtlich-medizinischen Alkoholbestimmung.** Von Prof. Dr. E. M. P. Widmark, Mediz.-chem. Institut der Universität Lund, Schweden. Neue Folge, Heft 11. Fortschritte der naturwissenschaftlichen Forschung. Herausgegeben von Prof. Dr. Emil Abderhalden. Paper. Price, 14 marks. Pp. 140, with 59 illustrations. Berlin: Urban & Schwarzenberg, 1932.

This monograph deals with the methods and results of recent work by the author on the determination of alcohol in the blood for medicolegal purposes. The work is based on the demonstration by the author that the concentration and conversion of alcohol in the organism may be followed as closely and accurately as the course of a reaction in vitro. The organism simply acts as a solvent of the ingested alcohol. First there is described a micromethod for the determination of ethyl alcohol in the blood, which does not require more than 100 mg. of blood, that is, no more than can easily be obtained in a capillary glass tube from the puncture of a finger tip. The principle of the micromethod is that of the commonly used bichromate method. Next come chapters on the diffusion of alcohol in the tissues, into the fluids of the body and the expired air, and on the kinetics of the conversion of alcohol and acetone in the organism. Then is described the Swedish official system of determining alcohol in the blood for medicolegal purposes on an extended scale. Police stations everywhere have at hand boxes with glass capillary tubes for the use of physicians in taking blood from persons suspected of being under undue alcoholic influence, as in motor traffic accidents. Boxes with blood-filled tubes and the data required are sent to the central laboratory. From the middle of May, 1930, to March, 1931, about 700 samples of blood were obtained in this way from the routine investigation of traffic accidents. The results of the general examinations and the alcohol determinations in these cases are presented in detail. Thus the proportion of the coarser symptoms of alcoholic intoxication to varying concentration of alcohol in the blood has been worked out: when the alcohol in the blood reached 1 per cent by weight, a considerable proportion of the cases showed definite symptoms of intoxication. In about three fourths of the cases the blood contained more than 1.4 per cent of alcohol. Full reports of especially interesting cases are given. The value of alcohol determination of the blood and urine in necropsies is considered on the basis of experiments and of results in medicolegal necropsies. In the presence of decomposition the determination of alcohol is not worth while—alcohol is broken down by decomposition. If the amount of alcohol in the urine is about the same as that in whole blood, the indications are that the consumption took place shortly before death; but if the amount in the urine exceeds that in the blood by 30 or 40 per cent, the indications point to little or no consumption since two hours before death. More has been said than necessary to show that Widmark's book is a contribution of fundamental importance in the work on the medicolegal problems of alcohol. The presentation is a model of clearness and order. Again a small country has demonstrated how practical progress may be made through well organized cooperation between officials, physicians and the scientific expert.

**Methods in Physical Education.** By Jesse Feiring Williams, M.D., Professor of Physical Education at Teachers College, Columbia University, John I. Dambach, M.A., Professor of Physical Education at the University of Pittsburgh, and Norma Schwendener, M.A., Associate in Physical Education at Teachers College, Columbia University. Cloth. Price, $2.25. Pp. 222. Philadelphia: W. B. Saunders Company, 1932.

This book seems to be designed for students who are preparing to be teachers of physical education and presents considerable material that has appeared in other works by Dr. Williams, together with new material having to do more specifically with methods of presenting and supervising physical activities. Neither material nor subject is of as much importance as in most of the other Williams books, and one suspects that its appeal will be much more limited. The bases of method in physical education teaching, anatomic, physiologic, psychologic and sociological, are presented; the principles of Dewey and Thorndike are applied again to this field of education; the essentials of learning and the stimuli for learning are discussed; and then applications of general principles are made to various phases of the physical education program, such as programs for young children, class efficiency, discipline, swimming, dancing and athletics. Many persons who are working with children would be glad if they could accept in toto this optimistic quotation from the chapter on discipline: "Children should wish to do those activities in which they engage. The teacher who studies the problem can control and direct the drives within his pupils; for him there are no disciplinary problems." A later statement in the same chapter presents a timely qualification, however: "Interest is a personal matter and one can never be assured that all the pupils in a class have been touched by the activity." On the whole, the book does not appear to be of great significance even to students of physical education.

**Leitfaden der Pathologie und Therapie der Kampfgaserkrankungen.** Von Dr. med. Otto Muntsch, Stabsarzt im Reichsheere, komdt. zum Reichsgesundheitsamt. Paper. Price, 10.50 marks. Pp. 94, with 28 illustrations. Leipzig: Georg Theme, 1932.

This monograph on the pathology and therapy of gas poisoning has as its objective the awakening of a wider interest on the part of the general medical profession toward the treatment of gas poisoning. The author seeks to bring this subject to the attention of the general practitioner, because, as he sadly admits, the probability not only of military but also of civilian exposure to war gases becomes ever greater. Under a pall of diplomatic pleasantries and assurances, every war department of the great military powers has systematically developed its gas service; the technic of the next war will merely magnify the lethal effects of a weapon which was just in its developmental strides at the end of the last one. The Chinese population of Shanghai has had a foretaste of military regard for civilian populations. Muntsch takes up in detail the effects of the commoner gases used in warfare and develops the rationale of therapy so far available. The book will be of some interest to members of the medical corps, but fortunately in our country there is no particular reason why the practitioner should devote time to this field. The subject matter is handled in a concise and clear fashion, the therapeutic suggestions are logical and practical, and the illustrations, many of which are in color, are excellent. There is a bibliography covering some of the pertinent literature.

**Psychological Racketeers.** By Dorothy Hazeltine Yates. Cloth. Price, $2. Pp. 232. Boston: Richard G. Badger, 1932.

Each new discovery in the field of science is likely to be adapted by quacks and exploiters for personal gain. One of the most recent developments has been the manner in which the new psychology of Freud and the practical psychology of many American teachers is being exploited by charlatans of one type or another. Obviously, the sexual side of the freudian psychology makes for the charlatan a special appeal. The quacks who work in this borderland include all sorts of psychologists, psychoanalysts, astrologers, phrenologists, spiritualists, graphologists, hypnotists, mental mystics, mind readers, mediums and mental scientists. Many of these charlatans have been described by the Bureau of Investigation of the American Medical Association. The usual "come on" is the free lecture with a special appeal to women. Frequently much is made of Hindu mysticism and magic. The great prizes offered are success in love and in business. A special appeal promises superiority to those who feel themselves inferior. In the book here under discussion, the author seems to be concerned with methods rather than with individuals, since most of the charlatans considered are not mentioned by name. One, Orlando Edgar Miller, has been repeatedly exposed in THE JOURNAL, and the author adapts this exposé to her presentation. The book contains much that is of interest, although amateurish in form and poorly published.

**Handbuch der normalen und pathologischen Physiologie mit Berücksichtigung der experimentellen Pharmakologie.** Herausgegeben von A. Bethe, G. v. Bergmann, G. Embden und A. Ellinger. Band XV, Hälfte 2: Correlationen 1/2. Arbeitsphysiologie II, Orientierung, Plastizität, Stimme und Sprache. Bearbeit von A. Bethe, W. v. Buddenbrock und anderen. Paper. Price, 80 marks. Pp. 835-1545, with 188 illustrations. Berlin: Julius Springer, 1931.

The last half of volume XV completes (except for the general index) this marvelous working tool in the field of normal and pathologic physiology. Twenty-three stout books make up this encyclopedic textbook of physiology in seventeen volumes. The entire set costs in the neighborhood of $460, a formidable price. However, no institution engaged in biologic research can well afford to be without it, if it is solicitous about conserving the time of its researchers. For many years to come this encyclopedia will be the standard set for rapid and authoritative references (especially of European literature). The present volume contains sections on respiration and circulation during muscular work; orientation in space among invertebrates, vertebrates and man; the sensory and motor apparatus of man as a whole; plasticity of the nervous system; plasticity of the organism on the basis of experiences in man with nervous lesions; plasticity and the doctrine of nervous centers; speech and the musical apparatus of animals and their mode of functioning; the vocal apparatus of man; the physical analysis of the voice and speech sounds; aphasia. All institutions are urged on this final occasion to favor themselves and their workers by having the entire "Handbuch" on their shelves. Its individual volumes may, however, be bought separately.

**Elementary Bacteriology.** By Joseph E. Greaves, M.S., Ph.D., Professor of Bacteriology, Utah Agricultural College, Logan, and Ethelyn O. Greaves, M.S. Second edition. Cloth. Price, $3.50. Pp. 535, with 138 illustrations. Philadelphia: W. B. Saunders Company, 1932.

This is essentially a reprinting of the first edition, since the changes are of minor importance. These include the mention of the electrophoretic method for determining relative virulence of certain organisms, the introduction of Bergey's classification of bacteria, a paragraph on diphtheria toxoid, and a few additions to the chapters on applied bacteriology. The book is truly a "general" bacteriology. The authors are particularly happy in their presentation of the relation of bacteria to the cycles of the various chemical elements.

**Leçons cliniques sur les maladies du sang et des organes hématopoïétiques.** Par Ch. Achard, professeur de clinique médicale à la Faculté de médecine de Paris. Paper. Price, 34 francs. Pp. 271, with 15 illustrations. Paris: Masson & Cie, 1931.

The interest among the profession in diseases of the blood-forming organs is reflected in the numerous works on this subject in the past few years. Many of these have dealt particularly with laboratory diagnosis and relatively few have stressed the clinical aspect. With the more accurate classification afforded by the improved methods of diagnosis, clinical observations and treatment have undergone changes. This book treats particularly the clinical phases of blood dyscrasias. The first two chapters are devoted to the hemorrhagic diseases. While the author presents a few departures in accepted methods of treatment, the pathogenesis is so incompletely understood that little advance has been made in this field. Pernicious anemia is considered with particular emphasis on some of the newer advances in therapy. Leukemia, agranulocytic angina and other blood dyscrasias are next considered. The organization of the book is essentially clinical. The author illustrates his discussion by presenting typical case histories with physical and laboratory observations. The work, while not exhaustive, is a comprehensive treatise on the clinical aspect of blood dyscrasias.

**Surgical Errors and Safeguards.** By Max Thorek, M.D., Surgeon-in-Chief, the American Hospital, Chicago. With a foreword by Arthur Dean Bevan, M.D., Professor and Head of the Department of Surgery, Rush Medical College of the University of Chicago. Cloth. Price, $10. Pp. 696, with 668 illustrations. Philadelphia: J. B. Lippincott Company, 1932.

The human being who is unable to learn from his mistakes is obviously little above the animal in intelligence. Indeed, this is probably the chief feature in differentiating between the human and the animal. It is quite human, however, to hide one's mistakes so that only the one who has erred benefits by the knowledge. Dr. Thorek has been exceedingly bold in the presentation of common surgical errors and analysis of their causation. He begins with a consideration of errors and safeguards in connection with surgical operations in general, including under this heading wound infections, acidosis, pulmonary complications and similar subjects. He points out the dangers of spinal anesthesia and the indications for its use and deprecates particularly snapshot diagnosis. The second chapter considers one of the most frequent alibis in medical work; namely, the bad risk patient. After a brief consideration of blood transfusion, the author discusses operations on the various parts of the body, concluding with a special chapter on defective instruments and foreign bodies left in the body during surgical procedures.

The volume is didactic, the sentences sharp and the pages frequently interspersed with heavy type, emphasizing significant points in anatomy or procedure. The illustrations are profuse, some of them borrowed but many taken from the author's own experience. A good bibliography supplements each chapter, and two excellent indexes make reference easy. Certainly every young surgeon should benefit by the experience here set forth.

## Medicolegal

### Civil Liability for Results of Criminal Abortion

*(Andrews v. Coulter (Wash.), 1 P. (2d) 320)*

Gene Raligh died after having been operated on with a view to procuring an abortion. The plaintiff, as administratrix of her estate, sued the physician who operated, to recover the expenses of the last illness and the burial of her intestate. A general demurrer, interposed by the physician, was sustained by the trial court. The plaintiff then appealed to the Supreme Court of Washington.

In the state of Washington, any one who unlawfully produces a miscarriage of a woman is guilty of abortion and may be punished by imprisonment in the penitentiary. The law provides, too, that a woman who submits to her own criminal miscarriage may be punished by imprisonment in like manner. Relying on these laws and on the general rule that courts will not aid either party in litigation growing out of criminal acts, the defendant physician contended for judgment in his favor, because the cause of action was founded on an illegal act on the part of the decedent.

There is a conflict of authority, said the Supreme Court, as to whether the rule that courts will not aid either party in litigation growing out of criminal acts shall be applied in favor of one who performs an abortion, when the woman consents and participates in the act. The court held, however, that in the state of Washington the rule is applicable. But, said the court, the complaint in this case does not charge simply an abortion and the consequent death of the woman. It contains further allegations that will permit proof that, on becoming aware that the patient on whom the abortion was performed was suffering from septicemia and peritonitis, the defendant physician wholly failed and neglected to prescribe for or treat her, and that, knowing that she was so suffering and that her life was in danger, and without letting her family know of her true condition, he wholly abandoned her. It was alleged, too, that had the defendant physician made known her true physical condition at the time it became known to him and had he given her proper attention, her death would not have occurred. Proof of the facts thus alleged would establish a cause of action. A physician and surgeon has no more right to abandon his patient under the circumstances of this case than he would had she become his patient under ordinary circumstances and in the best of faith.

The facts stated in the complaint were held to be sufficient to constitute a cause of action, and the cause was therefore reversed and remanded, with directions to the trial court to overrule the demurrer of the defendant physician.

### Buerger's Disease Aggravated by Trauma

*(Hall v. State Compensation Com'r. (W. Va.), 159 S. E. 516)*

Hall injured the great toe of his right foot. Two amputations followed, the second removing the entire toe. The wound did not heal, but Hall undertook to work, favoring his injured foot. While doing so, he rubbed the great toe on his left foot. Infection followed, which resulted in several progressive amputations, the last just below the left knee. In the meantime, the condition of his right foot became aggravated, necessitating a series of amputations, ending just below the right knee.

After his first injury and the consequent removal of the great toe of his right foot, Hall claimed and received compensation on a 10 per cent partial disability rating. Later, after the several amputations to which he had to submit, he sought supplementary compensation for the loss of both legs. Such compensation was refused, but on appeal the Supreme Court of Appeals of West Virginia remanded the case for a further hearing. The hearing was given, but a supplemental award was again denied, on the ground that the amputations to which Hall had been subjected were due to Buerger's disease, and not to the injury that he had suffered. The case was again appealed to the Supreme Court of Appeals of West Virginia.

The physicians were in agreement, said the Supreme Court, that Hall was suffering from Buerger's disease, or thromboangiitis obliterans, an inflammatory disease of unknown origin, affecting all the coats of the arteries and the veins. Practically all the medical witnesses expressed the opinion that the disease is not caused by trauma. They admitted, however, that such an injury as the claimant suffered might excite the condition and result in a loss of parts of the body several years earlier than they would be lost if no injury occurred. If the loss of Hall's legs were due to disease, and that disease was not aggravated nor accelerated by anything that might be denominated an accident, the loss would not be compensable under the workmen's compensation act of West Virginia. On the other hand, if the injury to Hall's great toe lighted up the disease from which he was suffering and incapacitated him for the performance of his duties, he was entitled to compensation. The several amputations to which Hall was subjected were, in the opinion of the Supreme Court, due primarily to the accident. The case was therefore remanded to the state compensation commissioner, with directions to fix the percentage of disability in accordance with the statute, based on the loss of both legs.

## Society Proceedings

### COMING MEETINGS

American Association for the Study of Goiter, Hamilton, Ontario, June 14-16. Dr. J. R. Yung, 670 Cherry St., Terre Haute, Ind., Secretary.

American Association for the Study of the Feeble-Minded, Philadelphia, May 26-29. Dr. Groves B. Smith, Godfrey, Illinois, Secretary.

American Association of Genito-Urinary Surgeons, Niagara Falls, Ontario, Canada, May 26-28. Dr. Henry L. Sanford, 1621 Euclid Avenue, Cleveland, Secretary.

American Gynecological Society, Quebec, May 30-June 1. Dr. Otto H. Schwarz, 630 South Kingshighway, St. Louis, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, May 23-25. Dr. Robert L. Loughran, 33 East 63d Street, New York, Secretary.

American Neurological Association, Atlantic City, June 6-8. Dr. Henry Alsop Riley, 117 East 72d Street, New York, Secretary.

American Ophthalmological Society, New London, Conn., June 27-29. Dr. Emory Hill, 501 East Franklin Street, Richmond, Va., Secretary.

American Orthopedic Association, Toronto, Canada, June 15-18. Dr. DeForest P. Willard, 1916 Spruce Street, Philadelphia, Secretary.

American Pediatric Society, Rochester, Minnesota, May 26-28. Dr. Hugh McCulloch, 500 South Kingshighway, St. Louis, Secretary.

American Psychiatric Association, Philadelphia, May 30-June 3. Dr. Clarence O. Cheney, 722 West 168th Street, New York, Secretary.

American Urological Association, Toronto, May 30-June 2. Dr. Gilbert J. Thomas, 1009 Nicollet Avenue, Minneapolis, Secretary.

Conference of State and Provincial Health Authorities of North America, Washington, D. C., June 2-6. Dr. A. J. Chesley, State Board of Health, St. Paul, Minnesota, Secretary.

Connecticut State Medical Society, New Haven, May 25-26. Dr. Charles W. Comfort, Jr, 27 Elm Street, New Haven, Secretary.

Maine Medical Association, Rangeley, June 16-18. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.

Massachusetts Medical Society, Boston, June 8-10. Dr. Walter L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.

Minnesota State Medical Association, St. Paul, May 23-25. Dr. E. A. Meyerding, 11 West Summit Avenue, St. Paul, Secretary.

Missouri State Medical Association, Jefferson City, May 23-26. Dr. E. J. Goodwin, 634 North Grand Boulevard, St. Louis, Secretary.

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

National Tuberculosis Association, Colorado Springs, June 6-9. Dr. Charles J. Hatfield, 7th and Lombard Streets, Philadelphia, Secretary.

Nebraska State Medical Association, Lincoln, May 24-26. Dr. R. B. Adams, Center McKinley Building, Lincoln, Secretary.

New Jersey, Medical Society of, Atlantic City, June 15-17. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.

New York, Medical Society of the State of, Buffalo, May 23-25. Dr. Daniel S. Dougherty, 2 East 103d Street, New York, Secretary.

North Dakota State Medical Association, Grand Forks, June 1-2. Dr. Albert W. Skelsey, 18 Broadway, Fargo, Secretary.

Oklahoma State Medical Association, Tulsa, May 24-26. Dr. Claude A. Thompson, Manhattan Building, Muskogee, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

Rhode Island Medical Society, Providence, June 2. Dr. J. W. Leech, 369 Broad Street, Providence, Secretary.

South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.

# *Current Medical Literature*

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Journal of Surgery, New York

**15:** 435-638 (March) 1932

Prostate at Crossroad. J. F. McCarthy, New York.—p. 435.
*Bone Sarcoma: Intramedullary Injections of Virus of Filtrable Fowl Endothelioma Tumor. R. F. Berg, Portland, Ore., with Foreword by W. B. Coley, New York.—p. 441.
Combined Roentgenologic and Clinical Differential Diagnosis of Benign and Malignant Lesions of Stomach. B. R. Kirklin and G. B. Eusterman, Rochester, Minn.—p. 462.
*Factors Influencing Prognosis in Medical Treatment of Duodenal Ulcer. Sara M. Jordan and E. D. Kiefer, Boston.—p. 472.
Diarrhea of Unknown Origin. P. W. Brown, Rochester, Minn.—p. 483.
Diagnosis of Jaundice: Value of Clinical and Laboratory Data. J. F. Weir, Rochester, Minn.—p. 494.
Psychiatric Aspects of Gastro-Enterology. A. Meyer, Baltimore —p. 504.
Acute Pancreatitis: Acute Hemorrhagic Pancreatic Necrosis. C. R. Jones, Pittsburgh.—p. 510.
*Unusual and Common Forms of Bacterial Dysentery Observed in the South. D. N. Silverman and W. H. Harris, New Orleans.—p. 515.
Studies in Gastric Secretion: Preliminary Note on New Method of Therapy for Peptic Ulcer. A. Winkelstein, New York.—p. 523.
*Combined Oral and Intravenous Cholecystography. P. B. Davidson, F. Biguria and J. Rosenthal, Boston.—p. 525.
A Urinary Antiseptic: Clinical Report. C. Rusche, Hollywood, Calif. —p. 545.
Tidal Irrigation and Suction Apparatus for Empyema. R. H. Overholt, Boston.—p. 548.
Unusual Case of Tuberculosis of Trochanteric Region: Bone Infection Near the Joint. E. D. W. Hauser, Chicago.—p. 551.

**Bone Sarcoma.**—In summarizing the results of his experiments, Berg calls attention to his artificial production of malignant tumors derived from filtrates of dried tumor tissue. From the artificially produced tumor tissue filtrates, other malignant tumors were produced which were dissimilar in respect to morphology, histology and dissemination of metastatic nodules. Culture of dried tissue, and filtrate on usual mediums showed no growth, but on special mediums positive cultures were obtained in all tubes with the dried tumor tissue, and one showed growth with the filtrate. The tumors produced were classified from roentgen, gross, histologic and clinical examinations in the following types: (1) endotheliomas, (2) endothelial myeloma, (3) osteogenic sarcoma, (4) giant cell tumor and (5) epithelial tumor.

**Prognosis in Medical Treatment of Duodenal Ulcer.**—Jordan and Kiefer report that nearly half of all cases of duodenal ulcer treated medically have one or more recurrences within a period of five years after treatment. About one fifth of the recurrences can be ascribed to carelessness on the part of the patient. A little over one fourth of the remaining recurrences are characterized by gross hemorrhage, which is not associated with pain or other important symptoms. Among the clinical features that are manifest in the examination and treatment of cases of duodenal ulcer, there are some with important prognostic significance, others with suggestive but inconclusive prognostic value, and others which give no aid whatever in estimating the probability of success or failure of medical treatment. The two features that are important enough to be useful in planning treatment for the individual patient are, first, the history of two or more gross hemorrhages, and, second, the demonstration of a marked intolerance to alkali therapy. Among the features characteristically more common in cases that are ultimate failures on medical treatment but are not sufficiently important to make them conclusive indication for or against medical management are failure of the duodenal cap to show improvement in outline after treatment, the six-hour retention of barium in the stomach particularly if still present at the end of three weeks' hospital treatment, a history of one gross hemorrhage, a marked resistance to neutralization of the gastric contents with alkali therapy, occult blood in the stools particularly if there is a tendency to persist on treatment, and the physical observations of hypertension and epigastric tenderness. The features that have little or no prognostic value are age, sex, age at the onset of symptoms; duration of the disease, severity of pain, degree of deformity of the duodenal cap at the first examination if there is no six-hour residue, and the degree of hyperacidity after an Ewald meal. Improvement in the roentgen appearance of the duodenal cap was found to be the most reliable single objective test as a guide to medical management. Alkalosis was found to be associated in a large proportion of cases with hypertension, other evidences of chronic vascular nephritis, and obstructive surgical lesions in the urinary tract.

**Bacterial Dysentery Observed in the South.**—Silverman and Harris have encountered several varieties of bacterial dysentery in a survey of approximately 100 cases of this disease. The bacillary types, especially the strains of Flexner, Shiga and Duval, are endemic in the South and appear to be increasing in incidence. Recent reports from northern sections of the country would warrant careful investigation of suspicious cases for the possible determination of a wider dissemination of bacillary dysentery than is at present suspected. Several unusual types of bacterial dysentery, in some instances with few previous clinical or bacteriologic descriptions, are found to exist in the South.

**Combined Oral and Intravenous Cholecystography.**—According to Davidson and his associates, cholecystography by the combined oral and intravenous method presents an accuracy comparable to that of the intravenous method. It produces a higher incidence of filling and denser shadows than the oral method. Reactions are infrequent; those present are apparently due to the dose taken by mouth. It is time saving, requiring but little more than the oral method yet requiring no repeat examinations. Cholecystography by the combined oral and intravenous method is the most satisfactory means of studying ambulatory cases.

### Archives of Ophthalmology, Chicago

**7:** *357-498 (March) 1932*

Ocular Injuries: Their Treatment. G. H. Cross, Chester, Pa.—p. 357.
Prognosis of Certain Eye Injuries. E. S. Sherman, Newark, N. J.—p. 361.
Workmen's Compensation Problems. V. A. Zimmer, New York.—p. 367.
*Ophthalmologic Importance of Focal Infective Prostatitis. P. S. Pelouze, Philadelphia.—p. 372.
Ioskiascopy Test. J. I. Pascal, Boston.—p. 378.
Ways in Which Distance of Test Field Affects Determinations of Retinal Sensitivity. C. E. Ferree and G. Rand, Baltimore.—p. 383.
*Homatropine and Atropine Cycloplegia: Comparative Study. L. Bothman, Chicago.—p. 389.
Correction of High Myopia by Mueller's Contact Glasses. N. Blatt, Targu-Mures, Roumania.—p. 399.
Orbital Metastases from Malignant Tumors of Suprarenal Gland. F. E. Burch, St. Paul.—p. 418.
Eyes of Irradiated Human Embryos: Further Observations. I. Goldstein and D. Wexler, New York.—p. 434.

**Focal Infective Prostatitis.**—Pelouze believes that the general focal infective triad in the male is teeth, tonsils and prostate. In eye conditions the facial sinuses also play a part. Focal infective eye conditions occasionally are due solely to infections of the prostate. They commonly are kept up by prostatic infections after the removal of foci in the teeth, tonsils and sinuses. Such prostatic infections usually are secondary to tonsillar or dental infections and only rarely have any relation to gonococcal infection. At least 35 per cent of all men beyond the age of 35 have a prostatic infection. At least 72 per cent of all men with focal infective symptoms have an infected prostate. These prostatic infections cannot be permanently cured so long as their causal foci in the teeth or tonsils persist. An increase in ocular symptoms usually follows one of the first digital manipulations of the gland. If no such increase occurs, the gland is practically acquitted as a factor in the causation of the eye lesions. This increase in ocular symptoms is analogous to a vaccine reaction with marked specificity for the distant lesion caused by the prostatic infection. Treatment of the gland, therefore, must be viewed from the standpoint of ocular tolerance to toxin. To exceed this threshold of toxin tolerance is to incur great risk. Recovery from such ocular conditions is retarded by severe reactions and hastened by treatment causing the slightest or no reaction. Prostatic massage should not be carried out oftener than twice a week. It should not be repeated within three days of the subsidence of a reaction caused by a previous treatment. If the eye condition improves as the result of prostatic massage and then remains stationary, there probably is a recurrent dental infection, the supposedly normal tonsils are in reality infected ones, or there is further trouble in a facial sinus. If the eye condition becomes worse as the result of prostatic massage of the gentlest type, it is evident that the toxin threshold is so low that the prostatic manipulations should be stopped until the eye condition reaches a stationary stage or definitely improves. Few methods of treatment require more judgment and restraint than does the attack of a prostatic infection in the presence of a focal infective eye lesion.

**Homatropine and Atropine Cycloplegia.** — Bothman describes experiments in which he demonstrated that atropine is a better cycloplegic than homatropine. He believes that it should be used more in refraction, especially in myopia. When persons with good unaided vision accept weak minus corrections under homatropine, refraction should be done under atropine.

Diagnosis and Treatment of Milder Affective Disorders (Depressions and Elations). L. F. Barker, Baltimore.—p. 273.
Relation of Tuber Cinereum to Gastric and Cardiac Functions: Preliminary Note. J. Beattie, Montreal.—p. 278.
*Glycosuria in Pregnancy. Lillian A. Chase, Regina, Sask.—p. 279.
*Pregnancy Glycosuria and Prenatal Care. V. J. Harding and D L. Selby, Toronto.—p. 283.
*Discussion on Etiology and Specific Treatment of Arthritis. F. T. Cadham, Winnipeg, Manit.—p. 287.
Intestinal Erepsin and Phosphatase of Infants with Acute Intestinal Intoxication. G. E. Hall, E. J. King, J. R. Ross and M. M. Shaw, Toronto.—p. 293.
*Effect of Irradiated Foods on Calcium and Phosphorus Metabolism. T. G. H. Drake and F. F. Tisdall, Toronto—p. 296.
Phlyctenular Conjunctivitis in Relation to Tuberculosis in Children. H. I. Kinsey, Toronto.—p. 298.
What Can Be Done in Some Cases of Advanced Malignant Disease? L. J. Carter and R. P. Cromarty, Brandon, Manit.—p. 302.
Tularemia: Report of Case. R. M. Shaw and H. C. Jamieson, Edmonton, Alta.—p. 305.
Chest Radiography and the Practitioner. P. M. Andrus, London, Ont. —p. 308.
Amebic Liver Abscess. Florence J. Murray and P. K. Koh, Ham Heung, Korea, Japan.—p. 312.
Thrombosis of Cerebral Vessels in Infants. R. Simpson, Toronto.—p. 317.
Iodine Poisoning and Iodism from Lipiodol. D. A. Carmichael, Ottawa, Ont.—p. 319.
Modified Tonsillectomy Procedure. C. K. Fuller, Yarmouth, N. S.—p. 321.

**Glycosuria in Pregnancy.**—Chase found sugar in 66 of 100 urinalyses of pregnant patients. One patient who did 100 urinalyses found sugar 47 times. The earliest time in pregnancy that sugar was found was two months. Sugar tolerance curves were done on three pregnant patients and on three patients in whom glycosuria had persisted after delivery; the curves were similar to those found in persons with renal glycosuria. On the basis of her observations, the author concludes that glycosuria in pregnancy is normal. Its frequency depends on how thoroughly it is sought. It does not require dietetic treatment and probably does not predispose to the development of diabetes. It is differentiated from diabetes by the small amount of sugar present, by the absence of thirst, and by the presence of normal blood sugar curves.

**Pregnancy Glycosuria and Prenatal Care.**—Harding and Selby believe that if all pregnancies or a high percentage of pregnancies show glycosuria and are physiologic in character it seems unnecessary from the purely clinical standpoint to distinguish between a glycosuria and a lactosuria, as usually recommended. If the distinction between dextrose and lactose were readily and clearly made, the authors would advise otherwise, on the grounds of completeness of data. In view of the uncertainty of the distinction by the present suggested tests, they think the wiser course is to assume the presence of a glycosuria.

**Etiology and Specific Treatment of Arthritis.**—Cadham has had the opportunity to observe the effects of treatment with autogenous vaccines of some ninety patients suffering from chronic polyarthritis. In over eighty of these patients the use of the vaccine was followed by some amelioration of the symptoms, and in many cases by complete relief; a few patients showed no benefit.

**Effect of Irradiated Foods on Calcium and Phosphorus Metabolism.**—Drake and Tisdall report that the administration of vitamin D in the form of irradiated muffets and farina to children from 9 to 11 years of age on a low calcium diet resulted in an increased efficiency in the utilization of calcium and phosphorus. Also the results furnish further evidence of the importance of vitamin D in human metabolism at periods other than infancy.

Etiologic Relationship of Certain Grain Fungi to Acrodynia, Thrombo-Angiitis Obliterans and Related Conditions. J. Klein, Chicago.—p. 254.
Cervical Phlegmon Following Local Tonsillectomy: Report of Four Cases. J. W. Hayden, Chicago.—p. 257.
Traumatic Lesions of Urogenital Tract. C. M. McKenna, Chicago.—p. 259.
Rôle of Orthopedic Surgery in Infantile Paralysis. J. L. Porter, Evanston.—p. 262.

**Correlation of Clinical Manifestations and Pathologic Changes in Nephritis.**—Simonds believes that for practical purposes, both clinical and pathologic, nephritis can be conveniently divided into two main groups: the cases in which the primary damage is to the secretory portion of the kidneys, and those in which the primary lesion is in the smaller arteries and arterioles. Cases of the first type may be acute, subacute or chronic and have been variously termed parenchymatous nephritis, glomerulonephritis and nephrosis; those of the latter group are practically always chronic and include the so-called chronic interstitial nephritis and arteriosclerotic, primary and genuine contracted kidneys. These two groups are each characterized by definite morphologic changes in the kidneys and each affects the functions of these organs in a different manner. In the first type the secretory portion of the kidneys is primarily damaged. The effect of this on the functions of these organs is to increase the permeability of their filtration apparatus. There is no retention of waste products in the blood or of dye in renal function tests, but a retention of crystalloids in the tissues, perhaps as a sort of compensatory mechanism, with resultant edema. In the second type the secretory portion is not primarily damaged. The alteration in function is due to disturbances in the circulation through the arterioles with reduction in blood volume and blood pressure, and, therefore, of available filtration pressure, within the glomeruli. An increase in systemic blood pressure temporarily compensates for this condition, but sooner or later retention of waste products in the blood occurs. The increased quantity of urine of low specific gravity is the result of inadequate absorption by the tubules because of interference with their nutrition. In the treatment of these two types, quite different methods would appear to be rational. In the first type a high protein diet should aid in restoring the depleted serum albumin. Reduction of water intake and of salt in the diet should aid in relieving the edema. In the second type a high protein diet would add to the nitrogenous waste products, which the kidneys are already unable adequately to excrete. Normal or abundant water intake might aid in flushing out the accumulated waste products.

**Atypical Scarlet Fever.**—Love calls attention to the fact that the character of scarlet fever has changed in recent years and a mild atypical form is very prevalent. Careful examination and prolonged observation is often necessary to diagnose these cases. Early diagnosis and recognition of the mild atypical case is a great factor in preventing the spread of scarlet fever.

**Edema of Larynx.**—According to Sneller, laryngeal edema, producing acute laryngeal obstruction, is caused by or associated with a great variety of conditions and diseases. It is the most frequent cause of acute laryngeal obstruction. An early diagnosis of the cause is essential for the most efficient treatment of the laryngeal obstruction. The degree of acute laryngeal obstruction has no direct relation to the seriousness of the condition or disease. Tracheotomy is preferable, particularly in acute laryngotracheobronchitis, when secretions become tenacious and abundant. Intubation may be preferable if edema is not great, if duration of intubation is short, and if tracheobronchial secretions are not tenacious and abundant. The prognosis is more dependent on the general toxemia than on the laryngeal obstruction itself, provided this is relieved fairly early.

Studies of Calcium and Phosphorus Metabolism: XIV. Relation of Acid-Base Balance to Phosphate Balance Following Ingestion of Phosphates. W. T. Salter, R. F. Farquharson and Dorothy M. Tibbetts, Boston.—p. 391.

*Studies in Parathyroid Physiology: III. Effect of Phosphate Ingestion in Clinical Hyperparathyroidism. F. Albright, W. Bauer, Dorothy Claflin and Jessie Reed Cockrill, Boston.—p. 411.

Specific Dynamic Response to Protein of Individuals Suffering from Disease of the Hypophysis. Margaret Woodwell Johnston, Ann Arbor, Mich.—p. 437.

*Stimulation of Gastric Pepsin by Histamine. W. S. Polland, San Francisco.—p. 449.

**Intravenous Injections.**—Beard and Blalock performed all their experiments on dogs that were deeply anesthetized by sodium barbital. Shock was produced by continuously passing the intestine between the fingers. Blood serum and the fluid that escaped into the peritoneal cavity were collected frequently for the studies. In the first group of experiments, studies were performed on the blood serum and the peritoneal fluid during continuous trauma to the intestine. No fluid was administered. Among the observations were the following: 1. There was a great diminution in the volume of plasma in the circulation. 2. The protein content per unit volume of serum remained approximately the same throughout the experiments. 3. The total protein content of the blood serum and of the peritoneal fluid was approximately the same in all instances. 4. The content in albumin of the peritoneal fluid was usually greater than that of the blood serum and the content in globulin was less. In the second group of experiments, various solutions were injected intravenously at a constant speed while the intestine was being traumatized. Among the observations were the following: 1. The total protein content of the blood serum and of the peritoneal fluid that were collected simultaneously was approximately the same in all experiments. 2. The albumin content of the peritoneal fluid was usually greater than that of the blood serum, while the globulin content was less. 3. The injection of solutions of sodium chloride and dextrose was usually associated with a decrease in the percentage of protein per unit volume of serum, a diminution of the volume of plasma in the circulation and a great decrease in the absolute plasma protein. 4. When solutions of acacia were injected, there was a decrease in the percentage of protein, an increase in the plasma volume and a decrease in the absolute amount of plasma protein. 5. The injection of blood serum was usually associated with comparatively small alterations in the percentage of protein, the volume of plasma and the absolute amount of plasma protein. 6. When whole blood was injected, there was very little alteration in the percentage of protein in the blood serum. Since there was a tremendous increase in concentration of the blood, there was probably a rather large reduction in the plasma volume and in the absolute amount of plasma protein.

**Studies in Metabolism of Sodium r-Lactate: I.**—In seven essentially normal children Hartmann and Senn studied the effects of the intravenous injection of from 4 to 7 cc. of molar solution of sodium r-lactate per kilogram of body weight, with the following results: 1. The racemic mixture is practically completely metabolized in from one to two hours. 2. The conversion of lactate into dextrose is apparent from the uniform rise of the latter in the blood. 3. The liberation of the sodium ion is practically quantitative, the base appearing in the body fluids chiefly as sodium bicarbonate. 4. Excretion of excess base into the urine takes place promptly, and alkalosis is usually of short duration. 5. During the period of alkalosis, no signs of tetany were noted.

**Celluloid Capsule for Measuring Venous Pressures.**—Krogh and his associates describe a celluloid capsule for the determination of venous pressures. This is easily made, and notches can be cut so that it will fit any arrangement of veins. It is cemented to the skin with collodion. When with high venous pressures the necessarily high intracapsular pressure would cause distortion of the skin and erroneous readings, the error can be avoided by the use of a counter-weighting clamp, also described. Such a counterweight is usually needed for the measurement of venous pressures above 30 cm. water pressure.

**Cutaneous Respiration in Man: VI.**—Ernstene and Volk made measurements of the effect of epinephrine, pituitary posterior lobe extract, histamine and pilocarpine on the rate of cutaneous respiration in three normal subjects. None of the drugs significantly altered the rate of carbon dioxide elimination and oxygen absorption through the skin. The failure to affect the rate of cutaneous respiration indicates that the drugs did not significantly alter the metabolic rate of the skin or the tension of the gases in that portion of the blood in equilibrium with the tissues.

**Studies in Parathyroid Physiology.**—Albright and his associates treated three patients with clinical hyperparathyroidism by ingestion of phosphates with beneficial results. The metabolic sequelae of such treatment are: (1) almost complete absorption of phosphates into the blood stream; (2) rapid excretion of the absorbed phosphates by the kidneys; (3) a rise of the previously low serum phosphorus; (4) a fall of the previously elevated serum calcium; (5) a rise at first of the calcium × phosphorus product in the serum; and (6) a fall of the urinary calcium excretion. The net result is an increase in the balances of calcium and phosphorus and a return of the serum levels of both in the direction of normal. The rapidity with which the absorbed phosphorus is excreted in the urine and the resistance which the low serum phosphorus exhibits to being raised suggest that the threshold for phosphorus excretion into the urine is lowered in hyperparathyroidism, and the authors consider this the most fundamental change in the calcium and phosphorus metabolism in this condition. It appears that in long standing hyperparathyroidism there is increased absorption of calcium and phosphorus from the gastro-intestinal tract and that excretion of calcium into the gastro-intestinal tract is not a threshold phenomenon dependent on the level of serum calcium.

**Stimulation of Gastric Pepsin by Histamine.**—Polland presents evidence to show that, in human subjects, histamine stimulates secretion of gastric pepsin. The character of the pepsin curve and the similarity of the response after the second and third injections of histamine can be interpreted satisfactorily only by assuming that histamine stimulates the peptic cells. The effect after the first stimulus is probably best explained by a mechanical lavaging of pepsin which has accumulated in the furrows and tubules of the gastric mucosa plus an actual stimulating effect by the histamine. Therefore it appears that, in studying gastric secretion in human subjects, histamine is suitable for determining the capabilities of the pepsin-secreting glands as well as the acid-secreting glands. Although the two processes are independent, they are influenced by the same stimulus.

**Carbohydrates Adsorbed on Colloids as Antigens.**—Zozaya presents evidence that polysaccharides can be rendered antigenic by haptogenic adsorption on a colloid carrier. The polysaccharides studied were those of Bacillus anthracis, the meningococcus, Streptococcus viridans (Bargen), Bacillus proteus, Bacterium morgani, Bacillus dysenteriae, both the Shiga and Hiss types, and the pneumococci. With the polysaccharide of type III pneumococci, the author was unable in six weeks to produce any detectable protective antibodies, but he was able to produce anticarbohydrate antibodies. All the bacterial carbohydrates were nonantigenic alone when used in the doses indicated, though containing some nitrogen. Dextran, which was free from nitrogen, was also rendered antigenic by the adsorption method.

**Determination of Lung Volume by Respiration of Oxygen Without Forced Breathing.**—Sendroy and his associates describe a method for estimating the volume of air in the lungs by the familiar principle of mixing this air with a measured volume of oxygen, and determining the extent to which the nitrogen of the pulmonary air is diluted. By employing a scrubber to remove carbon dioxide, and by measuring the volume of gas in the extrapulmonary part of the system at the end instead of the beginning of the respiratory period, it is possible to prolong the period to as many minutes as are necessary for complete mixture of the gases, and thereby to carry out the estimation without forced breathing. The determination can be carried out with the Roth-Benedict or Krogh spirometer, described by the authors, assembled from ordinary laboratory equipment. The method gives the same results as the hydrogen method of Van Slyke and Binger, and obviates the use and analysis of hydrogen. The relative advantages of the two methods are discussed.

**Action of Specific Enzyme on Dermal Infection with Type II Pneumococcus.**—The action of the enzyme which specifically decomposes the capsular polysaccharide of type III pneumococcus was tested by Goodner and his associates in type III pneumococcus dermal infections in rabbits. When injected in sufficient amounts, this enzyme is capable of bringing about a favorable and early termination of the experimental disease, which ordinarily is fatal in nearly all instances. The results of the study yield further evidence that the capsular substance is of great importance in pneumococcus infection, since, in so far as known, the only action of which the specific enzyme is capable is that of decomposing the capsular polysaccharide.

**Coryza, Pharyngitis and Sinusitis in Man.**—According to Webster and Clow, persons free of pneumococci, Hemophilus influenzae and Streptococcus hemolyticus are in general free of coryza, sore throat, and influenzal and sinus attacks; persons who are occasional or periodic carriers of these organisms may be negative on tests over long healthy periods but generally become positive during or following attacks and subsequently become negative again; finally, persons who are chronic carriers show during these illnesses increasing numbers of organisms in the throat and extension of the organisms to the nose. The authors made an addition to the knowledge of the mode of spread of these organisms. A focus of growth and dissemination was determined in the nasal passages and throat of individuals with chronic disease of the upper respiratory tract, and increases in numbers of the organisms at the focus and their spread to contacts were related to the winter season and to the occurrence of symptoms in the carrier. The observations suggest that the dosage of these organisms in a community is controlled by the resistance of the carrier and of the contacts. This view is in agreement with the facts derived from studies of native animal infections.

**Appendicitis Under Two Years.**—Kempton emphasizes the fact that the possibility of appendicitis should be kept in mind regardless of age. Appendicitis is a rare disease in the first year of life, somewhat more frequent in the second year, and gradually increases in frequency during the years of early childhood and young adult life. Owing to indefinite symptoms, difficulty of careful abdominal palpation and failure to have the condition in mind, it is likely that many cases go undiagnosed during the first two years of life. Abdominal palpation, together with white and differential blood counts, should be routine in all cases with symptoms of vomiting or abdominal pain. Rectal examination and examination under light anesthesia may be useful aids in making the diagnosis.

***Rehabilitation of Patients with Anterior Poliomyelitis.***—Capener believes that every case of anterior poliomyelitis demands, in its treatment, the cooperation of an orthopedic surgeon at the earliest possible date. Careful anatomic and physiologic studies must be made if adequate measures are to be taken in the prevention of deformities and loss of function.

In the reeducation of paralyzed muscles, the most valuable physical therapeutic measure is the warm brine bath. In the acute stage, irritative physical therapy is to be condemned. The optimum position of joints for the return of muscle function is discussed and apparatus described for the retention of these positions. In the later stages of the disease, operative treatment is used to correct deformities, stabilize joints and reestablish muscle balance.

**Acute Otitis Media and Its Complications.**—Costen states that the red drum without tympanic fluid or bulge is the one that responds to general measures. The bulging drum with tympanic fluid under pressure has the best chance of recovery without incident if incised early under careful aseptic precautions. Frequent irrigation with sterile physiologic solution of sodium chloride is a good localizing and therapeutic agent and can be handled at home, where most ear infections are treated. Simple mastoidectomy is without shock and is promptly to be advised if otitic sepsis is progressive. A residual headache or pain over the eye on the side of the ear infection, even if drainage from the ear has subsided, should be regarded with grave concern, especially in adults or people of advanced age. Frequent, small transfusions of whole blood, used early, continuously and late, are of the greatest value in any case of severe otitic sepsis.

**Hyperpyrexia in Treatment of Dementia Paralytica.**—Robinson and Johnson believe that no one form of treatment should be rigidly adhered to in private practice in dementia paralytica. Hyperpyrexia is the type of treatment that gives the best results in dementia paralytica and should be given early before ganglion cell death has become too widespread. Of all hyperpyrexic methods, diathermy is the most easily controlled, has fewer complications, can be used in cases in which all other forms of treatment are contraindicated, and is as efficient as any other method. A hopeless prognosis in the individual case should never be given; early heroic methods may help in cases that are seemingly hopeless.

**Bacterium of Acute Rheumatism.** — According to Whitaker, investigations both of human subjects and of experimental animals point to the incidence of the streptococcus as the sole organism in acute rheumatism. Different strains of streptococci are responsible. This is evidenced by the results of blood and tissue cultures isolated from rheumatic cases. A case of acute, fulminant rheumatic disease with involvement of the heart, cerebral and spinal meninges, lungs and pleurae, is presented. A diplococcal organism, analogous in cultural reactions and microscopic morphology to the Diplococcus rheumaticus of Poynton and Pain, was isolated from this case. Such observations and past and present studies tend to dispute the nonhemolytic Streptococcus cardioarthritidis as being the sole cause of rheumatic fever.

**Intracistern Serum Treatment of Neurosyphilis.**—Viets believes that there are distinct advantages to the intracisternal serum method of treatment in neurosyphilis over other modes of therapy. The pain and sphincter weakness, often noted after intraspinal treatment, are avoided. By a careful checking of the tests in the cerebrospinal fluid each time an injection is made, the amount of treatment necessary to bring the spinal fluid to normal and the general prognosis of the case can be accurately gaged. The method may be used as an office procedure, thus keeping the patient at his normal occupation. The results obtained are better than with most other forms of treatment, especially in selected cases. Often rapid changes take place in the spinal fluid as the result of intracistern serum and as much is accomplished in a few months as is usually accomplished in a few years of intravenous treatment. The technic is not difficult to learn, but there are distinct dangers from the method in the hands of a careless operator. Treatment should be given not oftener than once in two weeks and should be continued until the spinal fluid has approached normal or is in its normal state.

**Changes in External Secretions of Pancreas and Liver.**—McClure and Huntsinger report that investigation of the literature shows that the great majority of observers have used analytic methods and experimental conditions for the study of the pancreatic fraction of duodenal contents which render problematic the clinical interpretation of the results obtained. However, a system of duodenal analysis has been developed which permits estimations to be made of both the pancreatic and the biliary fraction of duodenal contents, which are sufficiently accurate for reliable clinical interpretation. Using this system, the authors made a study of patients with cirrhosis of the liver, toxic jaundice, cholecystitis, cancer of the pancreas, uncomplicated duodenal ulcer and a smaller number forming a miscellaneous group, together with a series of patients who had undergone cholecystectomy. The observations warrant the following conclusions: Qualitative changes in the bile, interpreted as resulting from hepatic dysfunction, are the rule in organic diseases of the liver and gallbladder. The observations suggest that functional disturbances of the liver cells play an important part in the development of clinical jaundice. They indicate that toxic jaundice results from hepatic dysfunction rather than from occlusion of the common bile duct. In the absence of demonstrable lesions affecting the common bile or pancreatic ducts, mild pancreatic dysfunction occurred in the large majority of patients with hepatic cirrhosis, toxic jaundice and after cholecystectomy. This observation was interpreted as a result of hepatic functional disturbance, affecting interrelated pancreatic function. Hepatic dysfunction occurs in duodenal ulcer in the absence of demonstrable organic biliary lesions, as evidenced by qualitative changes in the bile. Pancreatic dysfunction may be the earliest objective evidence of malignant involvement of retroperitoneal lymph nodes. The observations confirm previous ones and show that abnormal pancreatic and biliary fractions of duodenal contents occur, respectively, when lesions obstruct the pancreatic or biliary ducts, in the presence of destructive lesions of either organ, in circulatory disturbances of them, and in the presence of functional disturbances without demonstrable organic basis.

Communicable Sore Eyes in the New-Born. A. B. Ingels, Providence. —p. *43.*

**Resuscitation.**—Miller states that resuscitation is possibly effective thirty minutes after the heart has ceased to beat. It should be persisted in for another thirty minutes before one loses courage. Infants have been resuscitated and have recovered when there had been no voluntary respiratory movements for two and a half hours. As long as the circulation is maintained, there is hope. When there is need for resuscitation, time must not be wasted in moving the patient or waiting for the arrival of an inhalator. Artificial respiration by one of the manual methods should be instituted as soon as possible and continued while the inhalator is on the way. When the inhalator arrives, it should be used even if respiration has been established by manual methods. In cases treated with carbon dioxide and oxygen, pneumonia does not develop, which was the regular sequence of carbon monoxide poisoning before the introduction of the inhalator. When artificial respiration must be performed for a long period, as in the paralysis of anterior poliomyelitis or in poisoning from morphine or alcohol, the Drinker respirator is invaluable. It produces efficient artifical respiration over periods of days or weeks without strain on the operator or damage to the patient.

**Alleged Impediment in Cystic Duct to Passage of Fluids.**—In experiments on seven dogs, Johnston and Brown could find no impediment to the passage of fluid through the cystic duct at pressures usually found in the biliary tract. At lower pressures there is, in some animals, an impediment to the passage of fluid from the gallbladder through the cystic duct, which is overcome at pressures of from 10 to 80 mm. of water. In three well preserved human cadavers the authors found no resistance offered to the flow of fluid through the cystic duct, nor were they able to demonstrate any in five fresh necropsy specimens.

**Relationship of Carcinoma of Body of Uterus and of Ovaries.**—Offutt reports that, in a series of 520 cases of adenocarcinoma of the body of the uterus, there was associated carcinoma of the ovary in 11.9 per cent, and in 616 cases of papillary cystadenocarcinoma of the ovary there was associated carcinoma of the body of the uterus in 8.6 per cent. The fallopian tube should be considered as one of the means through which transplantation takes place. Because of the similarity of the adenocarcinomatous cells in the embryologically similar tissues, it is often difficult to determine which carcinoma is primary and which is secondary and whether or not there may originally have been two independent carcinomas. In cases of carcinoma of the ovaries, the possibility of metastasis to the uterine endometrium, even when there is no gross peritoneal evidence of extension of the malignant growth, must be borne in mind. Because of this possibility, hysterectomy at the time of removal of the ovaries must be seriously considered.

**Abdominal and Pelvic Fascias with Surgical Applications.**—According to Davies, two systems of fascia are found in the abdominal and pelvic regions, the one a thick fibrous sheet which ensheathes voluntary muscle, and the other a fibro-areolar layer which surrounds involuntary muscle and organs. Organs and structures related to the skin develop in the subcutaneous layer, while organs and structures related to the abdominal and pelvic cavities develop in the subperitoneal layer. Areas subjected to pressure by distention of the organ or structure are protected by an increased deposit of adipose tissue in the areolar layer. Vessels traversing the fibro-areolar layer are surrounded by an increase of the fibrous tissue. The mesenteroid to each muellerian duct forms the lateral support of the adult uterus and vagina. The vagina, like the rectum, is a muscular tube composed of an inner circular and an outer longitudinal layer of involuntary muscular fibers. It is covered by fibro-areolar tissue. A delicate areolar tissue connects the vagina to the bladder and to the rectum, except in the region of the hemorrhoidal mesenteroid of the vagina. The lateral ligament of the uterus is thinner and wider than the corresponding lateral ligament or mesenteroid of the vagina. The lateral mesenteroid of the vagina is a trapezoid support formed by the vaginal vessels as they traverse the fibro-areolar tissue lateral to the vagina. The anteroposterior flattening of the uterus and the vagina is due to the lateral attachments. The cylindric shape of the cervix is due to the absence of a lateral attachment and the preponderance of circular fibers. The round and uterosacral ligaments are fibromuscular bundles in which the muscular tissue predominates. Side-to-side closure of the vaginal vault following complete hysterectomy will increase the efficiency of the lateral attachments. Plastic operations increase the general pelvic tone by increasing the tone of the lateral mesenteroid of the vagina. The passage of the middle hemorrhoidal vessels from the anterior surface of the rectum to the posterior wall of the vagina forms a distinct mesenteroid, which divides the rectovaginal area into a proximal four fifths and a lower one fifth. Postpartum cervical inspections are facilitated by traction, which is exerted laterally rather than anteriorly and posteriorly. Sulcus tears are often serious, because of a laceration of the vaginal plexus.

**Retroperitoneal Syndrome and Relation Between Kidney and Gastro-Intestinal Reflexes.**—From the point of view of their gastro-intestinal effects, renal reflexes are classified by Tixier and Clavel according to the organ in which they predominate, thus: 1. Renogastric reflexes. They are motor, secretory and vasomotor. Sometimes they are phenomena of stimulation, sometimes of inhibition. The pyloric sphincter is particularly sensitive to these stimuli. 2. Reno-intestinal reflexes. Some reflexes are secretory and vasomotor, others motor. Sometimes spasm is produced, sometimes paralysis. The large intestine is particularly sensitive to these reflexes; the rectum may be the site of similar phenomena, particularly in the course of violent ureteral irritation. 3. Peritonism of renal origin. These different reno-intestinal reflexes may be associated with one another or combined with cardiac, respiratory or vasomotor reflexes to cause a group of symptoms resembling those of peritonitis. The clinical picture is then made up of pain, contracture of the wall, distention, vomiting, arrest of feces and gas, and rapid pulse without fever. This, in the authors' opinion, is the pathogenesis of the retroperitoneal syndrome.

**Studies on Injected Varicose Veins.**—Lufkin and McPheeters state that thrombus formation in varicose veins treated by injection of even "mild" solutions depends on an injury to the endothelial lining of the vessel. Deposition thrombus usually forms the smaller portion of the total occluding mass developed after treatment. The larger mass consists of simple clot. Recurrence probably results from retraction of the clotted portion of the mass from the vessel wall between tributaries of the main channel, with reestablishment of circulation through the new channel.

**Epilepsy.**—Swift believes that the periodic convulsive seizures associated with so-called idiopathic epilepsy begin with a gradual accumulation of cerebrospinal fluid over the cortex and in the cisterns of the brain, causing a constant irritation to the cortex, particularly to the motor areas. The blocking of the cerebrospinal fluid may be due to inflammatory conditions of the arachnoid or pacchionian bodies, or be produced by pressure on any of the venous channels from the superior longitudinal sinus to the heart itself. A general state of hydration is essential for the convulsive seizure in all instances. Anomalous development of the venous dural sinuses is an important factor in epilepsy. Of these sinuses, the transverse sinus is of the most importance. In those cases of anomalous development it is possible, by mobilization of the transverse sinus, to restore a sufficient venous return to prevent, under normal conditions, an accumulation of cerebrospinal fluid in the subarachnoid spaces. The only complication that may arise during the course of this operation is postoperative hemorrhage. This can be avoided by careful attention to all vessels at the time of operation. Indications for this operation are the presence of anomalous venous sinuses in true epileptic patients with otherwise normal physical conditions. Contraindications for this operation are the presence of disturbances due to inflammatory conditions, resulting in obliteration of the openings into the superior longitudinal sinus (pacchionian bodies). Localized accumulations of cerebrospinal fluid over the cortex are, of course, not benefited by this operation. The results of this mobilization bring about a marked improvement in the mental condition of the patient, as well as a decrease to a large proportion of the grand mal attacks and, to a less degree, the petit mal attacks. The operation is applicable in only 20 per cent of cases.

**Marching Fractures of Metatarsal Bones.**—Straus calls attention to the fact that insidious fractures of metatarsal bones may occur after exhaustion of the normal muscle and tendon support to the foot. Such fractures occur without obvious trauma, and without sufficient immediate pain to notify the patient of the injury. Weeks later the developing callus becomes painful and calls attention to the lesion, but by this time the swelling is apt to be considered a neoplasm unless the observer is familiar with the picture of a marching fracture. Search of the literature shows that the problem has engaged several European authors, but no American and only one English article refers to it. The author reports a characteristic case of the lesion. The patient had been previously seen by good surgeons and roentgenologists, who had said she was suffering from a sarcoma, and she had been sent to the hospital to have an amputation of the leg. The author suggests that some cases of Deutschlander's disease may belong in this group of fractures of metatarsal bones.

**Total Rupture of Kidney.**—According to Stirling, traumatic injuries of the kidney are relatively infrequent as compared with injuries in other parts of the body. The relative proportion is approximately 1 to 1,000. A prompt and thorough examination, including cystoscopy, should be done in all cases in which injury to the kidney is suspected, in order to lower the mortality and reduce complications to a minimum. Hematuria is the sign seen oftenest, though one or more of the classic signs may be absent. The amount of trauma may bear no relationship to the extent of the injury, as complete rupture of the kidney has been known to follow simple injuries. Complications include injury to the peritoneum, with rupture of the liver, spleen and, in many instances, fracture of one or more ribs. In cases in which one or both poles of the kidney are torn off, nephrectomy should be done to prevent exsanguination. General supportive treatment, including blood transfusion, is of much help in combating the shock. Early exploration, with conservative surgery, offers the patient the best chance of recovery. This includes suture of the torn kidney and packing, if needed, for hemorrhage, together with drainage. The mortality when this has been done is low.

**Association of Angina Pectoris and Anemia.**—Porter studied two cases of megaloblastic anemia and angina pectoris. In each instance, relief was obtained by restoring the normal qualitative state of the blood by liver feeding. In the study of angina pectoris the possibility of an associated anemia as a possible precipitating factor must be considered; or a valuable therapeutic approach to the situation may be omitted. The author's study adds additional evidence to the "myocardial ischemia" conception of the pathogenesis of angina pectoris as opposed to the aortic theory.

**Clinical Study of Achlorhydria.**—For more than ten years Moore has been interested clinically in achlorhydria, and about five years ago his interest in this connection became acute when some peculiar cases of anemia in middle-aged women presented themselves. The anemia in these patients appeared at first sight to be pernicious in type, since there was atrophy of the lingual papillae associated with superficial glossitis and achlorhydria, and the patients had a sallow or subicteroid complexion. The blood examination, however, showed an anemia with a color index well below unity; megalocytosis was absent, and, although there was anisocytosis and poikilocytosis, the average size of the erythrocytes was not greater than normal; the anemia, therefore, was not addisonian in type. As the standard textbooks did not give any information about this syndrome, and as a superficial search of the journals furnished but little, it was evident that it was a form of anemia not generally recognized. During the following years the author endeavored to collect, and when possible to study, cases of this form of anemia —that is, cases of nonmegalocytic anemia presenting a low color index and achlorhydria; he succeeded in collecting thirty-three such cases, in each of which the hemoglobin content of the blood was under 70 per cent. During the same period he did fractional test-meal analyses on as many other patients as was possible, with the idea of obtaining some information relative to the incidence of achlorhydria in other diseases. Out of forty-seven cases of so-called secondary, hypochromic, or nonmegalocytic anemia, thirty-three, or 70 per cent, presented achlorhydria. Therefore this particular form of anemia is probably one of the commonest types of anemia encountered; it is certainly surprising that so little attention has been paid to it in the literature and that it has been so seldom recognized in practice. Out of eighty-three patients with diabetes mellitus, thirty-three, or over 39 per cent, had achlorhydria, and out of forty-seven patients with hyperthyroidism, thirty-seven, or over 78 per cent, had achlorhydria. There were 100 gastro-intestinal cases and 74 miscellaneous cases showing achlorhydria. Out of a total of 1,228 patients tested by the fractional test-meal method during three and a half years, 272, or 22 per cent, had achlorhydria, as judged by this technic. On the basis of his observations the author concludes that achlorhydria, besides being found in a certain proportion of apparently healthy persons, in many cases of gastro-intestinal disease, and in odd cases of miscellaneous disorders, is a frequent observation in diabetes mellitus and a still more frequent occurrence in hyperthyroidism and in the nonmegalocytic "hypochromic" anemia described. In the latter disease it seems to have caused relationship, direct or indirect, but in the light of recent work on pernicious anemia even this surmised causal relationship may ultimately prove to be incorrect. At any rate, this form of anemia is of frequent occurrence, and its adequate treatment with iron in the ferrous form, by mouth, gives satisfactory results.

**Clinical Aspects of Coronary Disease.**—Cotton emphasizes the fact that the indications for treatment of coronary thrombosis and angina pectoris are essentially different. Coronary thrombosis is an acute illness, sudden in its onset, and there may be rapidly developing symptoms of a grave heart condition. Morphine should be given in doses large enough to relieve the pain, which is an early and conspicuous feature of the occlusion syndrome. Rest in bed for at least a month is essential, preferably for six weeks; and every unnecessary movement should be avoided for two weeks, or longer if there are symptoms of shock, signs of embolism, or congestive failure. Good nursing and mild sedatives are more important than circulatory stimulants: mild purgatives and enemas are usually required if morphine is continued for any length of time. Digitalis is indicated when there are signs of congestive failure and the auricles are fibrillating or in a flutter; epinephrine should be reserved for patients with signs of heart block, and quinidine restricted to rare cases of paroxysmal tachycardia of unusual length. A convalescence of two months is always necessary *before allowing the patient gradually* to resume a part time or full time active life. Angina pectoris, on the other hand, is a chronic malady, and the treatment is ambulatory in most cases. When the attacks recur at frequent intervals or reach a stage of status anginosus, and the pain is not easily controlled by nitrites, a long rest in bed is indicated. Such patients are sometimes helped by chloral hydrate, or morphine given in sufficient doses to raise their pain threshold and keep them free from pain for a week or two. The therapeutic measures on which one must rely are based on restricting their activities, both physical and mental, and regulating their lives so that the extracardiac contributory factors aggravating the anginal syndrome may be eliminated or controlled; a suitable diet, a change of environment, and the treatment of focal sepsis form part of this regimen. It is doubtful whether drugs which are supposed to have a dilating action on the coronary vessels materially alter the course of the disease. For patients with cardio-aortic syphilis, iodides and mercury should always be prescribed; intravenous injections of arsenic are indicated in the early stages of the disease and can be given under conditions of rest in moderately large doses.

**Use of Vitamin B in Cases of Edema.**—Carmalt-Jones states that in 1918 Wenckebach described "the beriberi heart." In beriberi, right heart failure often occurs, in which there is grave edema, resisting cardiac drugs but disappearing at once on the administration of vitamin B. Profound edema is always of serious significance in heart failure with congestion in cases of rheumatic origin. Every hospital physician is familiar with rheumatic heart cases which are constantly in and out of the hospital, the intervals between the attacks progressively diminishing until the patients are admitted with extensive edema; this admission is generally the last. There are occasional exceptions, but extensive edema is often of the gravest prognosis in congestive heart failure. In the light of Wenckebach's paper, the author thought it would be wise to try the effect of vitamin B in such cases, to see if by this means any principle, the absence of which was causing the fatal result, could be supplied. He used it first in two or three moribund cases, in which its effect, if any, was quite insufficient to postpone death. A few less grave cardiac cases showed some improvement and afforded encouragement to proceed, but death was not prevented. In the edema of pernicious anemia, however, two striking results were obtained, and in some edemas of other origin the results were satisfactory.

### Indian Medical Gazette, Calcutta

**67**: 61-120 (Feb.) 1932

Result of Forecast of Cholera, Smallpox and Plague in India in 1931 and Forecast for 1932. L. Rogers.—p. 61.

**Mutation of Cholera Vibrios.**—Pasricha and his associates report that by subjecting to repeated cultivation on ordinary bile salt medium a freshly isolated cholera strain which is resistant to one or more types of choleraphage, and by selection of those colonies which behave differently from the parent colony, one can obtain colonies which differ in their morphologic, cultural and serologic characters. In an experiment which they performed, inagglutinable colonies and partially agglutinable colonies were derived from a good agglutinating colony. Some of the dissociated colonies lost not only the property of agglutinability with cholera serum but also the agglutinogenic power of the cholera vibrio. The serum prepared with the original strain possessed no appreciable amount of agglutinins for the serologic variants derived from the original strain. There is no definite order or stability of the serologic variants obtained. The evidence in the literature for the transformation of an agglutinating vibrio to a nonagglutinating vibrio is so slender and contradictory that no definite conclusions can be arrived at, and one cannot as yet establish a definite relationship between the vibrio of the disease and the vibrio found in nature.

**Nupercaine in Spinal Anesthesia.**—According to Dikshit and Rao, nupercaine is a drug of fairly high toxicity and its toxicity is increased in toxemic conditions. It has a powerful action on the cardiovascular system and produces a slowing and irregularity of the heart in small doses. Blood pressure is lowered and the splanchnic vessels are dilated. It markedly depresses the respiratory center and this action is manifested when the drug is injected intravenously or applied locally by injecting it into the cisterna magna. On the central nervous system it acts as a convulsant. Its action on the sensory nerves is marked, analgesia being produced in low concentrations. Clinically it has been found to be a drug of high potency and toxicity, and great care is necessary in its administration. Proper technic makes for success. Blood pressure is better controlled by giving ephedrine ten minutes after the spinal injection. Respiratory embarrassment is more to be dreaded than circulatory disturbances but is much less in frequency. Headache is the only important undesirable sequela and is amenable to treatment. The duration of analgesia and the degree of muscular relaxation are the distinctive features of the drug when given by the spinal method.

**Factors in Causation of Hydronephrosis.** — Hosford divides the causes of hydronephrosis into congenital and acquired. The term congenital hydronephrosis at once raises a difficulty in nomenclature, because there is a type commonly called congenital in which the dilatation affects mainly the pelvis of the kidney. In that the dilatation is probably not present at birth it is not really congenital, although the factors which cause it may be congenital. It is best to confine the term congenital to those types of hydronephrosis which are present in the new-born or are discovered after birth. It is found that they fall into two main groups: (1) those in which there is some discoverable mechanical cause obstructing either the ureter or urethra, and (2) cases of megalo-ureter combined with hydronephrosis in which there is no discoverable obstruction. In the first group the ureter may show a definite stricture, narrowing or fold, or it may present as an impervious cord. In quite a number of those cases showing distention of the bladder, as well as distention of the ureters and kidneys, some congenital mechanical obstruction can be found in the posterior urethra. The commonest is a valve, so arranged that it obstructs the downward passage of urine but does not prevent the upward passage of a bougie. In the second group, in which no obstruction can be found, the ureteral orifices and bladder sometimes share in the dilatation, though in others the kidney and ureter of one side are alone affected. The cause of the dilatation is unknown, but it has been suggested by some authorities that the explanation may be an embryologic one. It has been shown that the ureters in fetal life up to the third or fourth month are of large caliber, as compared with the size of the kidney and the rest of the body. Deficient development of the musculature of the ureter may be the cause. This musculature does not begin to develop until the third month—it begins at the lower end of the ureter and gradually spreads up to the renal pelvis. An imperfect development, a true hypoplasia of the muscle fibers, must be seriously considered as a possible cause. This possibility, in addition to the persistence of the wide caliber of the ureters as seen in early fetal life, may explain the condition of congenital megalo-ureters and dilatation of the renal pelvis. The author divides the causes of acquired hydronephrosis into two groups also: (1) cases in which there is a demonstrable macroscopic obstruction, and (2) cases in which there is no such obstruction. In the first group the obstruction may be due to a variety of lesions, among which may be mentioned calculus, neoplasms or tuberculous inflammation obstructing the ureter, ureteral strictures, and ureteral kinks. In connection with the last of these the author refers to aberrant vessels and abnormal mobility of the kidney. He does not deal with the question of urethral or bladder obstructions in the cause of hydronephrosis. The group of cases in which there is no demonstrable macroscopic obstruction is of much greater interest, and he refers to it at some length.

**Gold Salts in Rheumatoid Arthritis.**—According to Forestier, the action of the gold salt treatment in rheumatoid arthritis does not appear very quickly to clinical examination; at least two or three months elapse before definite changes in the condition of the patient are observed. The effect on the general condition is generally remarkable; a high percentage of rheumatic patients are pale, with a shallow café au lait color. After three months' treatment their color becomes normal and they look much stronger and less depressed. The action on the joints is different in cases of short and long standing; in the first, when there was only a synovial swelling, this disappeared progressively in two or three months in favorable cases and the joints became completely normal again. In the older cases, in which subluxations and stiffness accompanied chronic inflammation of the joints, the latter changes disappeared but the former were only slightly modified. The main cause of invalidism among rheumatic patients is the pain on active and passive movements; in the author's experience this diminished progressively after one month or more, and from that time the movements of the different joints were greatly improved. Three patients who had been bedridden for from four to six years were able to stand up and walk a few steps after the first series of treatments. The body weight showed in some cases an increase of a few pounds, but other patients lost a little weight when they were able to take a larger amount of physical exertion. Like the treatment with mercury, bismuth and arsenic, the gold salts also may cause reactions against which one should be on guard. Sometimes an increase of temperature and temporary rashes may occur; these appear in certain sensitive patients for no reason and could be considered as anaphylactic phenomena; they did not prevent the author from continuing the treatment. Sometimes, after from six to eight injections, toxic changes occurred. They consisted of two kinds: those on the mouth and those on the skin. In 20 per cent of the cases there was observed a mild form of stomatitis with erosion of the lips and tongue, which was severe in only four cases. The skin reactions were mostly morbilliform rashes, and in five instances erythrodermia with subsequent desquamation. One should always ask the patient when an injection is to be made whether the preceding one has caused any irritation in the mouth or on the skin; if there is the least doubt about it, the next injection should not be given, and a sufficient length of time should elapse before the treatment is resumed. To prevent any disorder of the mouth, the patients should clean their teeth with a tooth paste containing arsenic.

**Presymptomatic Tuberculosis in Children.**—Fletcher made a survey of fifty children, mostly of school age, who, at the time they were sent for, were considered healthy by their parents. Among the fifty were found four cases of "latent tuberculosis" (tuberculosis of childhood), four of enlarged lymph nodes of the tracheobronchial group, and five of nontuberculous fibrosis, making a total of thirteen cases in all. The tuberculin test gave the following results: Of four cases of tuberculosis of childhood one was plus plus, two were plus, and one was negative; of four cases of enlarged lymph nodes, two were plus, one was negative, and one was not done. It is concluded, so far as it can be from such a small number, that the tuberculin test is not a guide in a sufficiently important group of cases. As no case of tuberculosis of childhood developed, so far as is known, from contact with an open case of tuberculosis, it seems that there is still a large amount of accidental tuberculosis abroad—what the French call "tuberculose de la rue." In an American series, 91 per cent of children with roentgen lesions had no history of exposure. The probable period of development and resolution in favorable cases of "latent" tuberculosis in children is about three months. The shape and extent of the lesion by roentgenography is apparently not a guide to its severity or an indication of its prognosis. Clinical examination and the tuberculin test are not altogether reliable guides to the presence of "latent" tuberculosis.

Primary Pelvic Pneumococcus Peritonitis in Adult. Ledoux, Humbert and Gomet.—p. 198.

**Treatment of Tabetic Gastric Disturbances by Intravenous Injections of Atropine Sulphate.**—Alajouanine and Horowitz call attention to the almost constant favorable results they obtained in thirty cases of tabetic gastric disturbances treated by intravenous injection of atropine sulphate. The treatment consists of the injection intravenously of from 1 to 3 mg. of atropine sulphate, once or twice daily, for several days. The group studied included patients with sensory and sensory-motor gastric disturbances, sometimes with the sympathetic system, sometimes with the vagus nerve predominating; the attacks were brief, from three to four days, or prolonged from two to three weeks. In some patients, the fulgurating pains that accompanied the gastric disturbances also disappeared or were calmed after treatment. The authors did not find any contraindications to the treatment. In most patients the improved condition lasted from one to three years. Recurrences were again treated.

**Tuberculosis with Multiple Synovial and Serous Manifestations.**—Bezançon and his co-workers report a case which was diagnosed as bilateral tuberculous hydrarthrosis of the knees. They state that tuberculous hydrarthrosis of the joints is not as exceptional as a simultaneous infection of all the chief arthrosynovia. The serous manifestations were characterized by a double pleurisy complicated by pericarditis without the sign of any pulmonary lesion. The process next appeared in the synovial membranes of the knees, elbows, wrists and ankles, passing through a state of hydrarthrosis but leaving the subjacent bone, the articular surfaces and the ligaments clinically and roentgenologically intact. On the other hand, all the serous tissue, juxta-articular bursae and muscular synovial membranes of the tendons in and about the joints were infected, whether suppuration was present or not. As a whole, the lesions were cold and exudative from the beginning, but there were no active inflammatory reactions and the lesions were different from those described in the course of tuberculous rheumatism. Twice a focal inflammatory reaction appeared at the level of the hydrarthrosis of the knees after subcutaneous or intradermal injection of a small quantity of tuberculin. The authors state that it is exceptional to find multiple tuberculous localizations in an adult (40 years old) with predilection for the serous tissue, invading successively the pleura, the pericardium and all the main articular or juxta-articular synovial membranes and leaving intact the parenchyma and the subjacent bone.

*Typhobacillosis of Landouzy and Its Pathogenesis. A. Dufourt and P. Etienne-Martin.—p. 123.

**Treatment of Pneumococcus Peritonitis.**—Nové-Josserand states that, generally speaking, pneumococcus peritonitis is a pneumococcemia and a diffuse infection that can be localized in the lungs, heart, kidneys and other organs without showing these lesions clinically in the first period of the disease. No symptom is pathognomonic. The diagnosis should be established after a consideration of the symptoms peculiar to pneumococcus peritonitis and their evolution. The early age, female sex, absence of a prodrome, preexistence of a pleuropulmonary infection or, better, an angina, a rhinopharyngitis, an otitis or a vulvovaginitis, with progression to influenza, can lead to a presumptive diagnosis of pneumococcus peritonitis. Other symptoms are a sudden, violent onset with rapid elevation of temperature to 40 C. (104 F.) or higher, followed at the end of several hours by an almost complete lull in the pains and vomiting and a fall of the temperature to 38 or 38.5 C. (100.4 or 101.3 F.). Such sedations in appendicitis are not as marked. Examination of the abdomen reveals a slight distention without contraction of the wall and without distinct pain on pressure. The patient seems to suffer more from colic than from a peritoneal reaction. The right iliac fossa is supple and only slightly painful; one can palpate it deeply without feeling resistance. There are some forms that deviate from this semeiology and then early diagnosis is impossible. In regard to whether a surgical intervention is as urgent in pneumococcus peritonitis as in other forms of acute peritonitis, the author states that the intervention during the first hours is not without danger and is useless, since the diffuse and slight extravasation cannot be cleared up and the source of the infection cannot be removed because it is diffuse and often septicemic. But, in practice, the difficulty in differential diagnosis from appendicitis does not contraindicate a surgical intervention. Diagnosis is often possible, and when it is sufficiently certain, a delay, while the patient is being observed closely, is necessary, since, in diffuse forms, operative indications can be noted after the second day. If the diagnosis remains doubtful, it is best to intervene, but one should proceed in such a manner as to render as little harm as possible.

**Spontaneous Nontuberculous Pneumothorax in Nurslings.**—Gardère and Savoye state that spontaneous nontuberculous pneumothorax is not very rare in early infancy and it is more frequent than tuberculous pneumothorax. It appears especially in the course of pneumonia, bronchopneumonia or pulmonary abscess, often secondary to one or another of the infections. The symptomatology varies with the intensity of the functional signs, the causal disease and the evolution. It may take the form in which the distinct clinical characters may be recognized at the bedside, or the pneumothorax may be more or less latent and can be recognized only in the roentgenograms. The transformation into pneumothorax in the course of bronchopneumonia with pulmonary abscess is frequent and often fatal. The prognosis depends on the causal infection. In the course of a pulmonary infection with medium intensity and favorable prognosis, the pneumothorax itself cannot be considered a serious aggravation and, in spite of early age, is well tolerated and improves rapidly. The presence of an extravasation, in the case of hydropneumothorax, is not an aggravating circumstance unless the liquid becomes purulent. Treatment consists of inhaling large doses of oxygen, and tonicardiac and sedative medicaments to attenuate the intensity of the dyspnea. In suffocating forms, which usually awaken latent lesions of the opposite lung, pleural puncture is indicated in order to diminish the tension of the gaseous extravasation. After the patient's condition has improved, it is sufficient to treat the causal disease. A pneumothorax in the pure state will undergo spontaneous resorption.

**Typhobacillosis of Landouzy and Its Pathogenesis.**—Dufourt and Etienne-Martin state that the clinical syndrome of typhobacillosis, as described by Landouzy, consists of a pretuberculous bacillary fever in which the temperature curve resembles that of typhoid. They describe thirteen personal observations of typhobacillosis in children. These cases prove that the disease appears suddenly in children in whom the temperature formerly was normal. Sometimes, other signs than a febricula may exist. The temperature may suddenly rise to 39 C. (102.2 F.) or above. Even though roentgen examination shows lesions in two thirds of the patients, the relationship between them and the fever is not explained, since analogous lesions are found in children that are in the period of primary tuberculous infection. The authors state that the tuberculosis is an early secondary complication of typhobacillosis and their coexistence should not preclude identity. This contemporaneous but not necessary manifestation of the primary infection proves the presence of a general infection. The fever is an autonomic entity and is not necessarily accompanied by anatomic lesions; it may depend on a blood infection brought about by a tuberculosis virus.

## Revue Sud-Am. de Méd. et de Chir., Paris

**3:** 1-96 (Jan.) 1932

Progressive and Total Suppression of Pancreas Does Not Produce Diabetes in the Dog. P. Escudero.—p. 1.
*Roentgenographic Image in Auricular Fibrillation. P. Cossio.—p. 19.
Clinical Aspect of Meteorology. A. Dias.—p. 29.
*Hemiplegia in Cerebral Hydatid Cyst in Child. L. Morquio.—p. 39.

**Roentgenographic Image in Auricular Fibrillation.**—Cossio states that since auricular fibrillation involves arrhythmia it ought to be recognized by electrocardiography and phlebography, which offer the means of analyzing, outside of the cadence of the activity of the heart, the succession of the phenomena that are produced during a revolution of the central organ of circulation. He had had occasion to study fifteen observations (one with an examination at necropsy) in which invariably a peculiar roentgen image coexisted with the auricular fibrillation. This image was characterized by the presence of a mitral configuration in its left contour and a double arc in its right contour. The author concludes that when one is in the presence of a cardiac image in which the left contour presents the characteristic of a mitral configuration and the right contour presents a double arc, the former due to the left auricle, one should consider a mitral disturbance in its final stages; namely, auricular fibrillation. However, even though the auricular fibrillation may be the consequence of a mitral disturbance, it does not always present a projection of the left auricle in the right contour.

**Hemiplegia in Cerebral Hydatid Cyst in Infant.**—Morquio states that his observations in five cases of cerebral hydatid cysts showed that the predominating phenomenon is a hemiplegic syndrome. It was the hemiplegia which guided his diagnosis. He finds that when the patient appears for the examination, the hemiplegia is generally complete, including the arm and the leg, in several instances also the lower part of the face. Dextrohemiplegia may consist of aphasia or temporary alteration in speech. The hemiplegia is spastic; there is a hypertonicity, exaggeration of the reflexes, clonus of the feet, epileptoid trepidation, and Babinski sign—all characters of secondary degeneration of the pyramidal tract. The opposite side is apparently free; sometimes, it is entirely normal, while at other times there is an exaggeration of the reflexes. The author did not consider complicated cases in which the stiffness affected the two sides equally. In several instances the leg, in other instances the arm, predominated. There was no disturbance in sensation. The hemiplegia is insidious, in one or two stages. Pure hemiplegia does not always exist. In hemiplegia of a cerebral hydatid cyst, one can find at the onset or after a while that the paralysis is more extensive than the hemiplegia; the patients have difficulty and almost absolute impossibility in standing and walking, so that functionally it is a complicated hemiplegia. The complication consists in more than just a paralytic accentuation, frequently, in a loss of equilibrium or motor coordination; but the ordinary movements can be made when lying down, indicating that the forces are conserved. The author believes that a diagnosis of cerebral hydatid cyst is possible in most cases. This diagnosis, in the majority of cases, can facilitate a surgical intervention at an opportune time. Four of his patients were operated on; two of these died and two were cured. An early diagnosis and an improved surgical technic will make possible more favorable results. For the formulation of a diagnosis of cerebral hydatid cyst, one should take into consideration the clinical characteristics, the previous signs and especially the origin of the symptoms.

**Subcalcaneal Exostoses.**—Mazzacuva found the proportion of acquired subcalcaneal exostoses much less than is commonly reported in the literature. It ranges, according to his experience, between 3 and 4 per cent. Of the many theories advanced for the etiopathogenic interpretation of calcaneal exostoses, the author thinks that none exactly fit all cases. Exostosis is a manifestation that has no etiopathogenic specificity, for which reason it is necessary to seek in each patient the local and general causes that may have brought about its appearance and growth. In none of the author's cases was he able to find a frank roentgen, clinical or anatomopathologic difference between the spurs that gave evidence of an associated infection and those presented by subjects without any previous infection that was demonstrable objectively or by the case history. The presence of mucous bursae in the tissues adjacent to the spur is an exceedingly infrequent observation and is interpreted as a protective reaction of the tissues secondary to the chronic traumatic stimulus caused by the exostoses. Bloodless treatment may produce excellent results, especially in cases of infective origin or in exostoses that, while of different origin, are single, of small volume, and when the financial circumstances of the patient are such as to allow him comparative rest for the limb for a period of several months. The treatment consists primarily in the adoption of specific therapy and, secondarily, in the application of an ordinary plantar orthopedic apparatus if the patient has flat feet. The immediate and remote results of open surgical treatment (which is always carried out in case of multiple exostoses that have shown no benefit from conservative treatment) are, in the author's experience, always excellent and such as allow the patient to resume completely and permanently his former occupation.

**Anisotonic Solutions in Treatment of Disequilibrium of Endocranial Pressure.**—Pozzi calls attention to the possibilities of anisotonic treatment in disorders of endocranial pressure, a form of treatment widely used in foreign countries but little known as yet, or at least little used, in Italy. The author discusses first the biologic principles on which this treatment is probably based and then reviews the various morbid conditions in which it is indicated. Then he considers the value of the treatment in acute disorders of endocranial pressure following craniocerebral traumatism (diffused cerebral compression and posttraumatic cerebral hypotension) and in disorders of neoplastic origin, in which it appears to be of advantage as a means of adapting patients to an operative intervention; as a mode of treatment of phenomena of acute hypotension that may be observed in the course of the intervention itself, and, finally, as a mode of treatment for postoperative cerebral hypotension due to protracted loss of cerebrospinal fluid from the wound. In view of its harmlessness, he considers this method of treatment deserving of confidence and of wide use in current practice.

**Gastrotonometry in Treatment of Gastric Leiasthenia.**—Martini and Curutchet's work is a continuation of previously reported work on gastrotonometry (intragastric pneumatic massage following intragastric insufflations of air) in the treatment of leiasthenia (asthenia of the muscles of the stomach with disturbances of the gastric motility, developing into dyspepsia). The technic and immediate clinical and roentgen results of the treatment were described in illustrations in *La Semana Médica* (**37**:1954 [Dec. 25] 1930). The treatment consists of one or two series each of ten intragastric insufflations of air. The insufflations are given at intervals of from three days to one week. The amount of air insufflated varies, according to the capacity of the patient's stomach, from 900 to 1,275 cc. The limit of distensibility of the stomach is determined by the appearance of a slightly painful tenderness in the patient's stomach during the insufflation. Rarely a second series of insufflations is necessary and, when it is, the insufflations should be given after a period of rest, which varies from one to two months, during which time the patient should be out of the hospital. Therapeutic intragastric insufflation has a mechanical action on the gastric muscles, by the successive distention and retraction of the organ, thus producing the effect of an intragastric pneumatic massage on the walls of the stomach. It has also a chemical action on the organ, by means of the insufflated gases. By this combined mechanical and chemical action, the stomach regains its muscular energy, contractility and tonus, and hence its functional normality. The authors obtained good results from the treatment in about 100 patients with functional motor gastric disturbances and dyspepsia of the second or third grade. They now report late clinical and roentgen results of the treatment in a patient belonging to this group, who had anorexia and progressive dyspepsia for seven years. When the patient began to receive the treatment, her condition was poor: she had lost about 20 Kg. (44 pounds). The treatment gave satisfactory results, which still persist three years after the treatment was given. From their experience, the authors conclude that therapeutic gastrotonometry is a harmless method of a simple technic and of great value in the diagnosis and therapy of disturbances of the stomach, especially those originating in faulty motor functions. The only contraindication to the application of the method is the presence of ulcers or neoplasms of the stomach. Therapeutic gastrotonometry is the most rational treatment of gastric atony, either simple or complicated by dolichogastry. The treatment may produce satisfactory results in cases in which other treatments, previously given, have failed. Patients are not subjected to the use of uncomfortable abdominal supports. As they recover they regain their normal weight without surpassing it. The increase of the gastric tonus under the influence of the treatment causes the disappearance of anorexia in 70 per cent of the cases. The method permits one to make gastrotonometric measurements of the gastric tension, the figures of which are so exact that even latent dolichogastry may be detected when the roentgen examination does not show as yet the presence of a diminished tonus of the gastric muscles. Therapeutic gastrotonometry is also of value in patients with splanchnoptosis and anorexia in whom fat therapy is indicated.

**Rôle of Colon Bacillus in Biliary Lithogenesis.**—D'Amato and Toroz made observations in forty-two patients with biliary calculi and in eighty-nine patients with other diseases than biliary calculi (either with or without lesions of the gallbladder). They conclude that the colon bacillus is a frequent cause of infection and the most frequent cause of biliary lithogenesis. The clinical picture of biliary lithiasis when caused by the colon bacillus is characterized by a prolonged and attenuated evolution of the disease. The patients have a subfebrile temperature with changes of an intermittent type and long remissions in the appearance of the symptoms. They give a history of intestinal disturbances with either constipation or diarrhea. As a rule, the bowels move every three or four days. The colon bacillus appears and disappears intermittently in and from the urine (and sometimes simultaneously in the blood and in the bile). Hence the advisability of a repeated bacteriologic examination of the urine (the most common route of elimination of the bacillus) if there are any symptoms of infection or intestinal disturbances. If one fails to identify the colon bacillus by the repeated bacteriologic examination of the urine in patients with biliary calculi, the etiology of the disease should be considered as of a noninfectious nature. Sixty per cent of the cases of biliary calculi are of infectious origin (40 per cent of which are caused by the colon bacillus). The colon bacillus may be identified simultaneously in the urine and in the bile or alone in the urine, but never alone in the bile. Colibacillemia may exist in patients with other diseases than biliary calculi. In some of these cases, catarrhal lesions in the gallbladder (the so-called lithogenic catarrh), which precede the formation of biliary calculi, are observed, while in other cases the liver and gallbladder remain normal. Renal calculi are a frequent complication in patients with biliary calculi and colibacillemia and a rare occurrence in patients with biliary calculi without colibacillemia. The identification of the colon bacillus from the urine in patients with renal lithiasis should make one suspect the presence of biliary calculi, which are discovered in all cases properly investigated.

**Early Reaction of Leukemic Spleen Following Roentgen Irradiation.**—In summing up the results of his studies, Windholz finds that if during chronic myeloid leukemia the spleen is irradiated on three successive days with a total of 12 Holzknecht units, changes are noticeable fourteen hours after the last irradiation. The changes are characterized by a disintegration of the cells of the myeloid proliferations and by signs of degenerative changes on the connective tissue framework. The protoplasm of the myeloid cells shows an increase in oxyphilia before changes develop in the nuclei of the cells. The cells of the leukemic proliferations show more pronounced regressive changes than the cells of the connective tissue framework. The proteolytic reaction of the irradiated portion of the spleen shows (on Löffler-serum plates) a more rapid increase than do the nonirradiated portions. However, this difference in the reaction is equalized in twenty-eight hours. It is assumed that the difference in the proteolytic reaction is not due to the fact that the rays produce larger amounts of ferments but rather to their increased rapidity of diffusion as a result of impairment of the cell membranes by the irradiation. It seems possible that a portion of the histologically visible changes, especially those on the lattice fiber system, can be traced to the influence of the ferments that become liberated during cell disintegration. Thus the visible initial reaction of the spleen following roentgen irradiation has two components: a degenerative change in the cells as the result of direct ray influence, and apparently secondary changes (of the connective tissue framework); namely, demonstrably increased fermentative action in the irradiated tissue.

**Significance of Small Salivary Glands for Lupus Vulgaris of Oral Mucous Membrane.**—Memmesheimer emphasizes that, in oral lupus vulgaris as well as in other forms of tuberculosis of the oral mucous membrane, an involvement of the small salivary glands should be watched for. In characteristic older cases of the disease the involvement becomes manifest in a certain hardness of the disease focus and of the nodules. If involvement of the small salivary glands is suspected, a deep exploratory excision and histologic examination is necessary. As treatment the author recommends extirpation or deep destruction by means of a cold caustic.

Idem. V. Morávek.—p. 509.
*Influence of Endocrine Glands on Development and Behavior of Experimental Cancers. W. Karnicki.—p. 523.

**Influence of Bacterial Filtrates and of Toxins on Tumor Cells.**—Segre first studied the influence exerted by filtrates of bouillon cultures of various bacteria on suspensions of different carcinoma cells. He observed that some filtrates are capable of attacking the cells of certain suspensions. The activity of the various filtrates against the different cell suspensions varies, and the susceptibility of a carcinoma cell suspension toward the various culture filtrates differs likewise. If carcinoma cell suspensions are exposed to the influence of true bacterial toxins, it can be noted that the influence is much less pronounced than if they are exposed to twenty-four hour culture filtrates of nontoxic bacteria. It was also noted that there is no relationship between virulence, pathogenicity and toxicity of a type of bacteria, and the capacity of its culture filtrates to attack tumor cells.

**Influence of Endocrine Glands on Development of Experimental Cancers.**—Karnicki studied the influence exerted by the organs of internal secretion on the neoplasms produced by application of tar on the ears of rabbits. He observed that the removal of the thymus influences the development of the neoplasms so that the growth is four times more rapid than usual. Extirpation of the thyroid and of the accessory thyroid likewise effects accelerated development of the neoplasms, but in a somewhat lesser degree than in extirpation of the thymus. The tumors show a great tendency to horny, conical formations. Since the thyroid plays an important part in the calcium phosphorus equalization and also has a great influence on the sympathetic nervous system, it is easily understandable that its removal produces favorable conditions for the development of neoplasms. After removal of the testes there is a less pronounced acceleration in the development and in the growth of the neoplasms than after extirpation of the thymus or the thyroid, but it is nevertheless considerable. Extirpation of a suprarenal inhibits the development and growth of the neoplasms, and a pronounced cachexia develops and progresses rapidly. If testes and thymus are removed simultaneously in the same animal, a considerable stimulation of the growth of the nodules is noticeable. In the later phases there is again a decrease, and the growth is less than in animals in which only the thymus or only the testes have been removed. Transplantation of thymus and of testes has an inhibitory effect on the development of neoplasms. The character of the precancerous formations in these cases resembles those that are observed in the suprarenalectomized animals. The neoplasm remains small, and cachexia is absent. Intravenous injection of preparations from thymus and testes effects a drying up of the nodules and destruction of the small growths. The larger nodules decrease in size and become soft after a certain number of injections. In the conclusion the author points out that his results not only prove his own theories but are identical with the results of a considerable number of investigators.

**Fracture of First Rib Caused by Muscular Traction.**—Adler points out that fractures of ribs caused by muscular traction are comparatively rare but, if they occur, it is usually the lower ribs that are involved. Fracture of the upper ribs, especially of the first one, by muscular traction is considered by some as impossible, yet several such cases have been reported in recent years. The author reports the case of a man, aged 54, who, while lifting a basket weighing about 20 Kg. (44 pounds) suddenly felt a cracking sound and then a severe pain in the region of the right scapula. A piercing pain persisted in the region of the shoulder and of the axilla, the neck became stiff, and the arm hung lifeless, only the fingers being movable. At first the diagnosis was not entirely clear, but fixation of the extremity brought relief. A few days later the patient stated that, although there was less pain, the slightest movement of the right shoulder joint and deep inspiration caused a cracking noise. Renewed examination of the patient corroborated this and roentgenoscopy revealed a transverse fracture of the first rib at the junction of the bone and cartilage. In discussing the causes of this fracture the author expresses the opinion that inadequate innervation of the muscles is one of the causal factors. That a greater brittleness of the bones, which may also be a causal factor, was not the cause in this case was proved by roentgenograms of several of the patient's bones, which were entirely normal. In the conclusion the author states that he shares Porzelt's theory of pathogenesis. Porzelt, who observed a case similar to that described by the author, maintains that the rib is extended not only by the lung, inflated by maximal inspiration, but also by forced tension or upward traction of the scaleni and the subclavius muscles; on the other hand, the arm lifting the load and the traction of the muscles of the chest press the clavicles on the extended first rib, and thus these two opposing forces cause a fracture.

**Fat Embolisms.**—Makai reports the clinical history of a man, aged 56, who sustained a complicated fracture of the leg. The fracture was reduced and then fixed with a plaster-of-paris splint. At first the patient was completely conscious, so that he was able to give orders and to read, but on the following day he became unconscious and restless. This condition persisted for several days, and when on the sixth day he came under the author's observation, a cerebral embolism was assumed and the injured extremity was immediately amputated. The improvement in the patient's condition was so evident after the amputation that a causal relationship can hardly be doubted. This case corroborates Kirschner's theory, who maintains that fat embolism not only develops immediately following a fracture but may develop later as result of incomplete fixation. If more and more fat enters the circulation, the sequelae, especially the cerebral symptoms, increase in severity, but if the source of the fat embolism is excluded the patient may recover. The author thinks that fat embolism may perhaps be more frequently the cause of temporary disturbances after injuries than is commonly believed. He suggests that the bronchopneumonia which so frequently develops in older persons after a fracture may be due to pulmonary fat embolisms. In regard to the treatment, he states that, in severe fractures with cerebral symptoms and shock, care should be taken to prevent repeated fat embolisms. Since in complicated fractures absolute immobilization may be difficult, amputation should not be shirked, for it may save the patient's life. Otherwise it can be attempted to counteract the threatening symptoms by resorting to venesection with subsequent infusion of sodium chloride or of sugar solutions, and by administration of epinephrine and solution of pituitary.

## Zentrablatt für Gynäkologie, Leipzig

*New Pregnancy Test on Male Mice by Means of Hormone Concentration. J. Czyżak.—p. 533.

**Therapy of Puerperal Pyemia by Ligation of Veins.**—In order to gain insight into the mortality of puerperal pyemia when conservative treatment is employed and thus to be able to estimate the urgency of a more radical treatment, Schellenberg studied the histories of patients with puerperal pyemia who received treatment in the women's clinic in Zurich in the years from 1911 to 1930. On the basis of these studies he concludes that early operation in puerperal pyemia can be dispensed with, since within a short time a definite diagnosis can hardly be reached, and thus many patients would be subjected to ligation in whom pyemia either does not exist or is so mild that spontaneous cure sets in. If ligation of veins had been resorted to after the third attack of chills, in more than 56 per cent of the cases studied by the author the patients would have been unnecessarily exposed to the dangers of a surgical intervention, and if it had been done after the second attack over 67 per cent would have been operated on without need. A late operation after a fourth attack of chills is advisable only in exceptional cases, since the mortality rate is about equal whether conservative treatment is done or operation is resorted to. The small difference in the percentages does not justify the exposure of the patient to the possibility of the failure of the operation.

**New Pregnancy Test on Male Mice by Means of Hormone Concentration.**—Instead of using female mice as in the Aschheim-Zondek pregnancy test, Czyżak made the test on male animals. He found that only a urine with concentrated hormonal content produced visible changes and he therefore injected the test animals with a concentrated urine. He describes the technic of the concentration and of the injection and states that after 100 hours the test animals showed a considerable increase in the size of all the accessory sex glands, especially the seminal vesicles. The test was made in 100 cases; namely, in 66 cases of early pregnancy, 18 cases of adnexitis, 10 cases of ruptured tubal pregnancy and 6 cases of ovarian cysts. In evaluating his test he takes the Aschheim-Zondek test as the standard of comparison. He admits that the use of female mice has two advantages over his use of male animals: 1. The reaction on female animals permits a differentiation of the presence of prolan A and prolan B. 2. The reaction is more exact, for while in male animals the size of the sex organs has to be compared, in female animals the presence or absence of hemorrhagic spots or of yellow bodies serves as an indicator. However, in spite of its deficiencies the author considers his test a valuable supplement to the Aschheim-Zondek reaction. An advantage is that in using males there is always a sufficiency of animals and the test requires only three animals instead of at least five, as for the Aschheim-Zondek reaction.

**Radiology in Treatment of Cancer of Larynx.**—According to Chochia, the predominant types of cancer of the larynx are basal cell, prickle cell and occasionally adenocarcinomas. Surgical treatment consists in radical excision of the cancer and the metastases in the lymph nodes. When the tumor has spread to the vocal cords, the ventricles and the cartilages, total extirpation of the larynx is indicated. This results in death in 50 per cent of the cases and with but few exceptions recurrence in the rest. The latter intervention and the results are so serious that few patients consent to the operation. Aside from surgery, radiotherapy (roentgen rays and radium implantation) was used. During the period 1919-1930, 112 patients (110 men and 2 women) were treated: 63 with roentgen rays, 33 with radium implants, and the rest with both roentgen rays and radium. The author concludes that radiotherapy, as well as surgical intervention, does not give striking results, although improvement is possible in a small percentage of the patients.

**Radiotherapy in Malignant Tumors of Urinary Bladder.**—Grosman treated thirty-nine patients with malignant tumors of the urinary bladder and nine patients with malignant tumors of the prostate. A review of the literature and the results of his own studies did not aid him to resolve on a conclusive treatment. Surgical measures were not sufficient and were indicated only in the early stages. Radiotherapy, and especially radium implantation, was an improvement, since it could be used not only in operative but also in neighboring and sometimes inoperable areas.

**Roentgen Therapy in Climacteric Deficiency Phenomenon.**—The climacteric deficiencies manifested in the study of Shekhter and Duboviy were mostly of a vasomotor character: flow of blood to the head, changes in cardiac rhythm, dizziness, palpitation of the heart, ringing in the ears. In many patients, arthritic symptoms and psychic disturbances were also present. Small doses of roentgen rays were given to thirty patients; in nineteen instances the hypophysis was irradiated, in seven instances the thyroid, and in four the hypophysis and the thyroid. In eighteen, or 60 per cent, of the patients the active hyperemia completely disappeared, and the palpitation of the heart and attacks of dizziness decreased; the ringing in the ears disappeared and sleep was improved. In nine, or 30 per cent, of the patients the active hyperemia became less intense. No change was noted in three, or 10 per cent, of the patients. Recurrences limited to active hyperemia occurred in a few instances from six to eight months after treatment; but these did not return after a second series of treatments. In the four instances, in which irradiation of one gland was unsuccessful and the other gland was subsequently irradiated, improvement was noted in one case only. The authors believe their favorable results substantiate the observations of Bokar, who believes that roentgen rays help to remove a hyperfunction in either the hypophysis or the thyroid.

**Cancerous Metastasis of Bone Simulating Primary Sarcoma.**—Korkhov and Mintz state that neoplastic metastasis in the bones may often mask the primary manifestations. He describes two personal observations. In one case, an osteoclastoma of the left scapula was found on roentgen examination to be secondary to a cancer of the left bronchus. In the second instance, roentgenograms proved the primary manifestation to be an ulcus carcinomatosum of the stomach with metastases in the pelvis, rib, pleura and lungs. The diagnosis before roentgenography in the second instance was sarcoma of the pelvis.

**Rare Localization in Osteochondropathy.**—Dubrovskaya describes an observation in which the diagnosis, after roentgenography of the 12 year old patient, was neoplasm of the proximal end of the fifth metatarsal bone of the left foot. The right foot showed similar but less intense changes. The author states that the change in the left foot was the result of a pathologic fracture of the necrotic bone with subsequent spreading of the necrosis. In the right foot the spread of the necrosis took place without a previous fracture.

## Hospitalstidende, Copenhagen

**75:** 213-240 (Jan. 21) 1932

*Roentgen Picture of Normal and Pathologic Sella Turcica. H. Scheuermann.—p. 213.

**Roentgen Picture of Normal and Pathologic Sella Turcica.**—Scheuermann examined roentgenograms of the cranium of 391 patients with a normal sella turcica and of 55 with brain conditions showing pathologic changes, and made comparative examinations of specimens of normal sella turcicas from 100 patients and of sella turcicas from forty-one with intracranial disorders. The technic in roentgen examination of the cranium, normal anatomy and roentgen pictures of sella turcica, position of the head in certain tumors of the brain, and primary and secondary enlargement of the sella turcica are discussed. There has been close agreement between the results of roentgen examination and of necropsy. The roentgenologist, he says, is to express himself concerning the pathologic changes revealed but to speak with reservation concerning the possible primary or secondary nature of the changes.

# SUBDURAL HEMATOMA IN INFANTS

MAX M. PEET, M.D.
AND
EDGAR A. KAHN, M.D.
ANN ARBOR, MICH.

In the past three years there have been admitted to the University Hospital nine infants with subdural hematoma. Since these cases are usually diagnosed as idiopathic hydrocephalus, we are reporting this series to stress the ease of differential diagnosis. The importance of making this distinction lies in the fact that idiopathic hydrocephalus is hopeless, while subdural hematoma is amenable to surgical treatment. There is no doubt that we, as well as others, must have frequently overlooked the condition.

## SYMPTOMATOLOGY

The symptom first noted is a gradual enlargement of the head, usually associated with convulsions. This is seldom observed before the age of 4 months. Though the shape of the head resembles that of hydrocephalus, the expression of the face is different. This, we feel, is a most important point. Instead of a dull, apathetic face, one sees a bright, alert expression, even though the eyeballs are displaced downward. In the far advanced cases this may not be true.

On percussion over the parietal region a dull note is obtained, while in hydrocephalus the note is tympanitic (McEwen's sign). A high-pitched note over a subdural hematoma in adults has been described by Rand.[1] The note in infants is, however, entirely different. On examination of the fundus, retinal hemorrhages and various degrees of optic atrophy may be seen and, occasionally, choked disk.

The diagnosis is established on puncture of the fontanel. If true hydrocephalus exists, the ventricle is usually entered at a depth of from 1 to 2 cm., colorless ventricular fluid being readily obtained. In subdural hematoma the fluid appears just after the click of piercing the membranous fontanel. It varies from slightly straw-colored to almost pure blood and gushes from the needle with each cry. One should not be confused here by subarachnoid fluid which might be increased by cortical atrophy and slightly colored by the trauma of the puncture. Immediate centrifugation will show in the latter condition a clear colorless supernatant fluid.

After reporting our cases, we will discuss the etiology, pathologic physiology and treatment.

## REPORT OF CASES

Case 1.—B. C., an illegitimate boy, was born at the Maternity Clinic of the University Hospital, Dec. 12, 1927. The delivery was normal and at term. He was placed on a formula ten days later. He was referred, April 17, 1928, because of a gradual enlargement of the head. There were no other symptoms except occasional vomiting.

Examination revealed a large, typically hydrocephalic head with a bulging fontanel. The eyes were displaced downward. The fundi showed both disks to be edematous. There were two large hemorrhages in the right fundus near the disk.

A ventricular puncture was attempted on the left without success. When the needle was removed, blood-tinged xanthochromatic fluid trickled from the puncture wound. A similar result ensued when the right side was tapped, except that the fluid was bloodier. Fluid was then aspirated from both sides and air injected. Roentgen examination revealed this to be extra-arachnoid. When both fluids were centrifugated, that on one side was seen to be deep yellow while the other was smoky reddish.

One of us (M. M. P.) made a right sided subtemporal decompression of about 30 mm. The dura was under marked tension and abnormally red. It was incised, and immediately xanthochromatic fluid spurted upward to a height of about 6 inches. When the pressure of the fluid had been exhausted the dura was widely opened. The brain, covered with arachnoid, immediately herniated slightly into the dural opening. There was considerable fluid beneath the arachnoid. This was aspirated with a fine needle and found to be perfectly clear. The brain was then depressed and a large amount of xanthochromatic fluid escaped from the anterior region. Herniation of the brain immediately ceased; in fact, it was sunken about 1 cm. below the temporal opening. No clots were seen, although the lateral aspect of the cerebral hemisphere was carefully explored throughout. The dura appeared pinkish. A piece was removed for pathologic examination. The wound was closed in layers.

Dr. Warthin's diagnosis was chronic pachymeningitis hemorrhagica.

A similar operation was performed on the other side a few days later with an entirely similar result.

The general condition was good postoperatively, but both wounds soon bulged with fluid subcutaneously. This was necessarily aspirated almost daily and was always xanthochromatic. Soon the downward gaze of the eyes disappeared. Six weeks later the shape of the head appeared almost normal. The accumulation of fluid, however, continued for about six weeks more. The patient was discharged apparently normal in appearance and mentality, July 11, 1929.

In considering this case in the light of our present knowledge, we realize that this was a mild degree of the condition we are discussing. There was undoubtedly an inner membrane lying over the arachnoid but it was so thin and transparent that it was not recognized. This inner membrane is ordinarily very firm and opaque, being usually strong enough to prevent the brain from expanding.

This case is undoubtedly the type that might regress spontaneously or after repeated punctures of the fon-

tanels. A report in October, 1931, showed that the head was apparently normal in size and that there was no bulging of the decompressions. The intelligence quotient was 68 by the Binet test.

Case 2.—D. H., an illegitimate boy, born at the Maternity Clinic, July 2, 1927, and placed on a formula almost immediately, was discharged to a nursing home as normal.

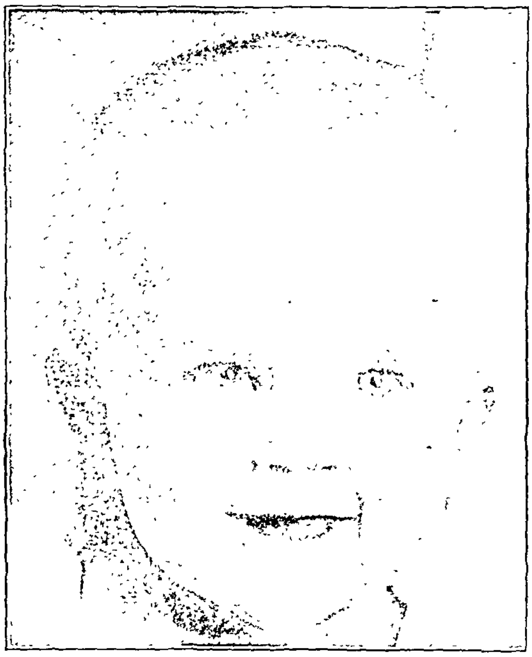

Fig. 1 (case 4).—Large head and normal facial expression. The fontanel is sunken from previous subdural puncture.

He was returned to the hospital three months later because he was not moving the left arm as formerly and was very apathetic. Examination by the department of pediatrics was negative: the anterior fontanel did not bulge and the head was apparently normal. The spinal fluid was negative.

He was admitted one month later because of a single convulsion and continued listlessness. He was a well nourished infant at this time. The head was enlarged and the anterior fontanel was bulging. There was a staring expression to the eyes. The Kahn test of the blood was negative. The fundi showed neuroretinitis with edema of the nerve heads.

Puncture of the fontanels revealed subdural bloody fluid on both sides, that on the right being darker. Air was injected on the right after the removal of about 40 cc. of fluid. Roentgenograms revealed the air-containing space to be limited posteriorly by the tentorium cerebelli, medially by the falx cerebri. It extended laterally over the parietal lobe. The normal convolutions of the brain which are ordinarily delineated when air is in the subarachnoid space were not seen.

A right sided osteoplastic flap was turned (E. A. K.), exposing the dura, which was under marked tension. The dark blue coloration indicated hemorrhage beneath. The dura was opened, exposing a gelatinous appearing cyst wall covering the entire brain. The cyst was opened, considerable hemorrhagic fluid escaping. The tough false membrane over the arachnoid was removed as far as possible, as well as the gelatinous lamination adherent to the dura. The condition became poor and the child died during the closure.

Case 3.—R. H., a boy, aged 6 months, admitted to the hospital, Oct. 10, 1928, had a normal labor. Cyanosis or convulsions were not present. The child had always been on a formula.

He was apparently well until about two weeks previous to admission when vomiting of a projectile type began. Convulsions had occurred twice in which the hands shook and the eyes rolled. The child was comatose for some time following each attack. The enlargement of the head was first noted at the onset of the vomiting and had progressed rapidly up to the time of entrance.

On examination the child appeared acutely ill. There was great enlargement of the frontal bossae. The anterior and posterior fontanels were widely open and there was considerable separation of the sutures. The veins of the scalp were dilated. The eyes were turned downward and in. The fundi showed bilateral choked disks. The blood Wassermann was ++++.

On puncture of the fontanels about 300 cc. of slightly bloody, orange-colored fluid was obtained from the two sides.

Antisyphilitic treatment was commenced. The subdural spaces were frequently tapped but there was no improvement after three months.

Jan. 16, 1929, under nitrous oxide anesthesia, a large, right sided osteoplastic flap was turned downward (M. M. P.). When the dura was opened there was an escape of a large amount of xanthochromatic fluid. Covering the inner surface of the dura was a definite membrane, which was quite adherent but could be peeled from the dura. The inner surface of this membrane was pinkish and shiny. The brain was displaced downward 3 or 4 cm. in the frontal region and less toward the parietal, so that the posterior parietal membrane, brain and dura were adherent. The displaced brain was covered with a semiopaque, pearly glistening membrane, which readily peeled from the arachnoid. A large portion of the dural membrane was removed, as was that over the displaced brain. The dura was partially closed and the osteoplastic flap returned to position. The incision was closed in layers.

About one hour later the patient suddenly became cyanosed, and respirations ceased shortly.

At autopsy, besides the subdural hematoma on the left side, there was well marked dilatation of all ventricles.

Case 4.—R. M., a boy, aged 10 months (fig. 1), a second baby, by a normal delivery, was placed on a formula at 2 weeks. Enlargement of the head was first noted at 4 months. It had gradually increased 1 inch. Convulsions of both a clonic and a tonic nature had occurred two or three times a month since the enlargement was first noted. Projectile vomiting was associated with these attacks.

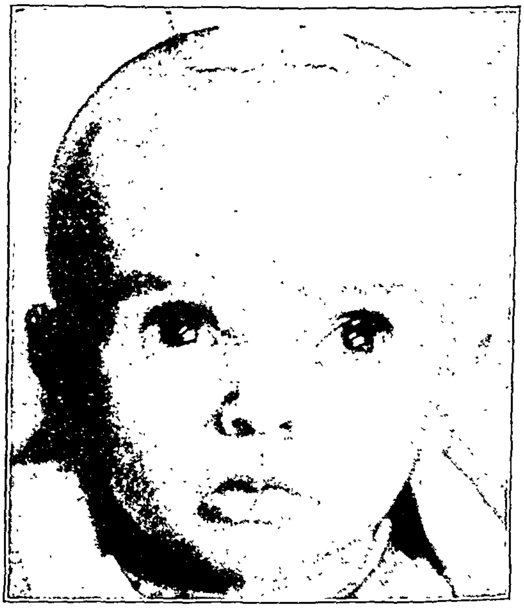

Fig. 2 (case 5).—Hydrocephalic type of head with a circumference greater than the chest. Bilateral fontanel punctures into subdural hematomas are sealed with collodium-cotton dressing.

The child had an abnormally large head and was unable to hold it up for any appreciable length of time. The expression of the face was that of a bright active child, and he smiled and laughed frequently. The anterior fontanel was large and bulging. The fundi showed no evidence of an increase in intracranial pressure.

On puncture of the fontanel the ventricles were not encountered. On the left, a large amount of bloody fluid was obtained from the subdural space. The fluid on puncture of the right fontanel was straw colored.

A right sided osteoplastic flap was turned (E. A. K.). The middle meningeal vessels were seen to be three times their normal size. When the dura was opened, it was easily separated from a cystic purplish gelatinous mass. Over 50 cc. of bloody fluid escaped when the mass was incised. A thin, tough, milky membrane covered the arachnoid and was stripped from it as far as possible.

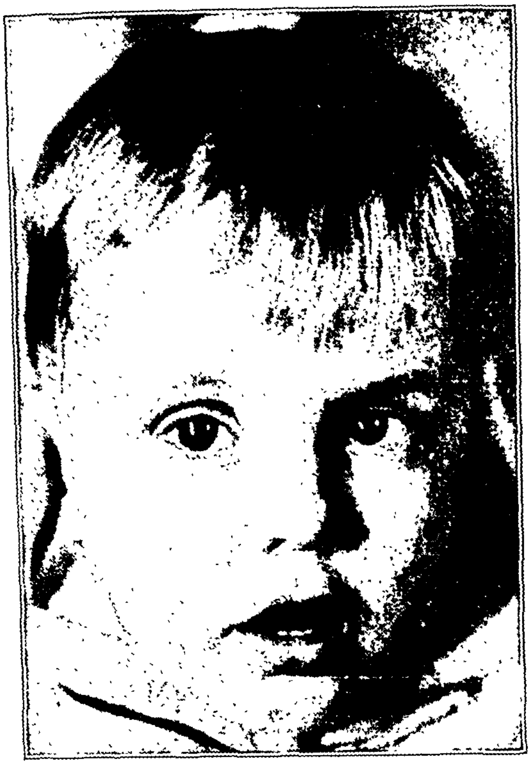

Fig. 3 (case 5).—Appearance of patient two years after operation.

Postoperatively the child seemed to be in excellent condition. Several hours later respirations suddenly became very shallow and the child soon died. A cause for the sudden death was not found at autopsy.

CASE 5 (fig. 2).—F. K., an illegitimate boy of a normal delivery, was born, Sept. 10, 1928, at the Maternity Clinic. The Kahn test was negative. The child was soon placed on a formula. He gained weight rapidly and was taken to a boarding home in November. At that time the head seemed larger than normal. About Christmas time a generalized convulsion occurred, and there was one following this.

The baby was returned for examination because of a continuous enlargement of the head, which presented a typically hydrocephalic appearance. There was some bulging of the anterior fontanel, and on percussion over the parietal bone a flat note was obtained. The appearance of the face showed no evidence of mental dulness. There was a peculiar bluish discoloration about the eyes. There was questionable early optic atrophy, with one hemorrhage in the left fundus. A diagnosis of pachymeningitis hemorrhagica was made.

Puncture of the fontanel on the left side revealed considerable clear yellow fluid. The fluid was very bloody on the right.

A few days later a bronchitis developed. Following this, a definite left sided bronchopneumonia was revealed by roentgen examination.

April 17, 1929, a small right sided osteoplastic flap was turned (E. A. K.). The dura was seen to be blackened and under considerable tension. A needle was inserted beneath the dura, and considerable bloody fluid was obtained, relaxing the dura. The middle meningeal vessels were ligated. The dura was opened with the base below. It stripped readily from a glistening, black, gelatinous membrane. This was opened, giving entrance into a cavity containing bloody fluid. The patient went into shock at this point, but on lowering of the head the condition improved.

The undersurface of the cavity was lined with a milky white membrane which covered a normal arachnoid. All the membrane was removed except for some far anteriorly. It did not extend posteriorly beyond the midparietal region.

The dura was closed with interrupted silk sutures and the wound was hastily brought together in two layers. The baby at this stage was in profound shock but rallied after a hurried whole blood transfusion.

The third day after operation, 100 cc. of bloody fluid was aspirated subcutaneously. Several more aspirations were necessary in the next ten days, following which there was no further accumulation.

June 9, a left sided osteoplastic flap was turned and a similar pathologic condition was found except that the fluid was somewhat less bloody. An attempt was not made to remove as much of the membrane as previously. Transfusion was performed at operation.

Postoperatively it was necessary to aspirate twice in about five days, but following this there was no further accumulation of fluid.

The patient was returned (fig. 3) for examination, November 1. He was walking and the nurse stated that he was "brighter than normal." He was again seen in June, 1931, at which time he was perfectly normal to all appearances.

CASE 6 (fig. 4).—R. C., a Negro boy, aged 13 months, who was delivered with instruments was in good health and was breast fed for ten months. His mother was a primipara with a history of a positive Wassermann reaction. He sat erect at 9 months. The past two months it was noted that the child was very irritable, that his appetite was poor and that he vomited frequently. The mother stated that the head had always been large.

Examination revealed a large globular head. The anterior fontanel was bulging. The facial expression was that of a normally bright child. The fundi showed early consecutive optic atrophy and no hemorrhages. There was dulness on percussion over both parietal regions. The Kahn test of the blood was negative and there were no signs of hereditary syphilis.

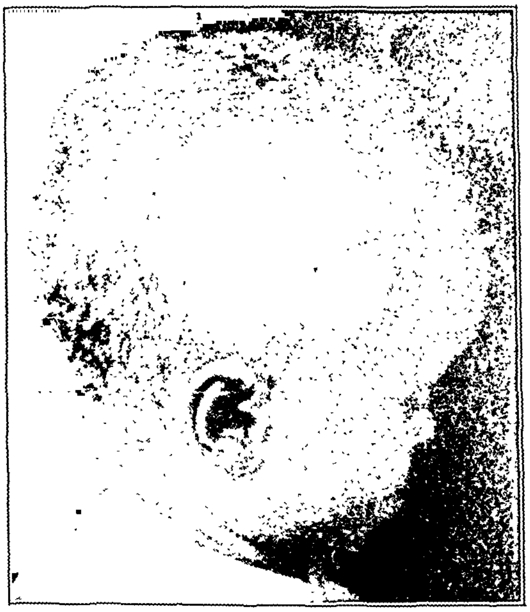

Fig. 4 (case 6).—Appearance two weeks after operation.

Subdural puncture of the right fontanel revealed about 40 cc. of very bloody fluid. On the left only a small amount of clear subarachnoid fluid was obtained. A diagnosis of right sided pachymeningitis hemorrhagica was made.

March 18, 1930, puncture of the left fontanel gave only a small amount of clear subarachnoid fluid. On right sided puncture about 30 cc. of very bloody fluid was obtained. A small right sided osteoplastic flap was then turned (E. A. K.). The dura was lax and when it was opened about 40 cc. of fluid escaped. The middle meningeal vessels were only slightly larger than normal and were secured with clips. The membrane on the dura was only about 2 mm. thick. It was stripped from the dural flap. No attempt was made to strip more of it from the surrounding dura. Though the arachnoid appeared normal, a thin greenish yellow membrane entirely covered it. This membrane was very delicate and was easily removed. The wound was closed in layers. The child was never in a serious condition during or after operation.

March 26, the bone flap was elevated by underlying fluid. About 80 cc. of bloody fluid was aspirated; March 30, 90 cc. was aspirated. It was necessary to aspirate the fluid every few days for a month. The fluid was then allowed to accumulate, raising the flap slightly. This disappeared spontaneously in about two weeks.

July 7, there seemed to be some fluid beneath the flap. On aspiration, 40 cc. of clear colorless cerebrospinal fluid was obtained. This was repeated a few days later. There was no further elevation of the flap and the child was discharged in good condition. The child was seen again in January, 1931. He was apparently perfectly normal. The mother had not noticed any increasing enlargement of the head. In October, 1931, the child was bright and symptom-free. Measurement showed no increase in the size of the head from the previous January (fig. 5).

We feel that, following operation and aspiration, the internal pachymeningitis had completely resolved or had organized in such a way that transudation no longer occurred. This meant the formation in so large a head of considerable dead space, which naturally became filled with cerebrospinal fluid. This accounts for the aspiration of clear fluid so long after operation.

Fig. 5 (case 6).—Appearance a year and a half after operation.

Case 7.—D. D., aged 10 months, a seven-months premature infant, had had a normal birth. It was the mother's seventh pregnancy. At the age of 4 months it was noted that the child was losing weight. There was a loss of appetite and diarrhea. At the time of entrance, the child had never sat alone. There was no history of convulsions.

The appearance was that of a greatly emaciated infant with a head suggesting hydrocephalus. The fundi showed slight secondary optic atrophy. The Kahn test of the blood was negative. On puncture of the fontanels the ventricles were not encountered, but from both subdural spaces straw-colored fluid was obtained.

Two months following admission, a right sided osteoplastic flap was turned (E. A. K.). A comparatively thin membrane was found beneath the dura. This was partly excised and the membrane covering the arachnoid was almost completely excised. There was an accumulation of about 60 cc. between the two membranes. About two hours after the operation, respirations suddenly ceased, the pulse continuing, however, for several minutes.

Case 8.—B. B., a boy, aged 6 months, was admitted because of increasing enlargement of the head, noted the past two months. There was no history of convulsions. He had been discharged from our maternity home at the age of 6 weeks in good condition. The mother was a primipara; the child, illegitimate.

The infant was well nourished. The head was typically hydrocephalic, the fontanel was large but not bulging. The coronal suture was open. There was dulness on percussion over both parietal regions. The fundi showed only slight pallor. On puncture of the fontanels, xanthochromatic fluid was found in both subdural spaces.

A right sided osteoplastic flap was turned (M. M. P.). Immediately beneath and adherent to the dura was found a dense false membrane, beneath which was a large organized clot. A firm membrane covered the arachnoid. Between this and the clot was from 200 to 300 cc. of yellowish, slightly bloody fluid. When the clot was removed, the brain did not expand. It did so only after the removal of the membrane covering the arachnoid. Beneath the arachnoid, clear fluid could be seen. The child left the operating room in fair condition. He continued to improve, when respirations suddenly ceased. The pulse could be felt for several minutes afterward.

Case 9.—B. L., an illegitimate child, had had a breech presentation. The Wassermann reaction of the cord blood was negative. He was immediately placed on a formula.

He was brought to the University Hospital because of a progressive enlargement of the head. The head presented the typical appearance of hydrocephalus with bulging fontanel, separated sutures and prominent scalp veins. There was dulness on percussion over both parietal regions. The fundi showed diffuse choroiditis and secondary optic atrophy.

Puncture of the fontanels revealed amber colored fluid on both sides. A diagnosis of bilateral subdural hematoma was made.

Under local anesthesia a large left sided osteoplastic flap was turned (M. M. P.). The dura was incised, making a flap with the base posterior. A thin subdural membrane covered the entire dura and was stripped off well to the frontal and occipital regions and from nearly the midline above downward into the floor of the middle fossa. There was a large amount of bloody fluid covering the cerebral cortex. When this was evacuated it was seen that the combined pressure on the brain coupled with the distention of the skull had pushed the dura so far away from the brain that there was a space of at least 1 inch between the inferior longitudinal sinus and the surface of the cortex. The cortical veins passing to the superior longitudinal sinus had been stretched until they were from 1 inch to 1½ inches long. A thin yellowish membrane, rather opaque and very tough, enclosed the cerebral cortex. This was stripped away, allowing the brain to expand. All the blood on the right side was thoroughly irrigated away, the dura closed and the osteoplastic flap returned to position. The scalp incision was closed in layers.

The postoperative condition was fair. Transfusion of 100 cc. of whole blood was done. Ten days later a right sided osteoplastic flap was turned under local anesthesia (M. M. P.). A similar condition was encountered. The two hematomas communicated beneath the falx. This was the only case in which this was found. Postoperative aspiration was performed six days later and was repeated every few days for one month, when the fluid had practically disappeared and no further aspiration was necessary.

## ETIOLOGY

Trauma is undoubtedly the most important factor, as stressed by Trotter.[2] Malnutrition, however, may predispose to this condition. None of our patients were breast-fed for any length of time except patient 5. Five of our patients were illegitimate, having been cared for in institutions. Sherwood[3] has noted the etiology of this malnutritional factor. Five of his nine patients had been cared for by foster mothers or by charitable institutions. O. Rosenberg,[4] who has had a most extensive experience with this condition, stated that he had never seen it develop in a healthy, normally developed, breast-fed child.

### PATHOLOGIC PHYSIOLOGY

It would seem that there is a definite sequence of events. There first occurs a hemorrhage into the subdural space. This is undoubtedly from the superior cerebral veins which run from the cortex to the dura or longitudinal sinus. They have a comparatively short, vertical course in the subdural space, as shown by Trotter.[2] In one adult, we found the vein which apparently had caused the original hemorrhage.

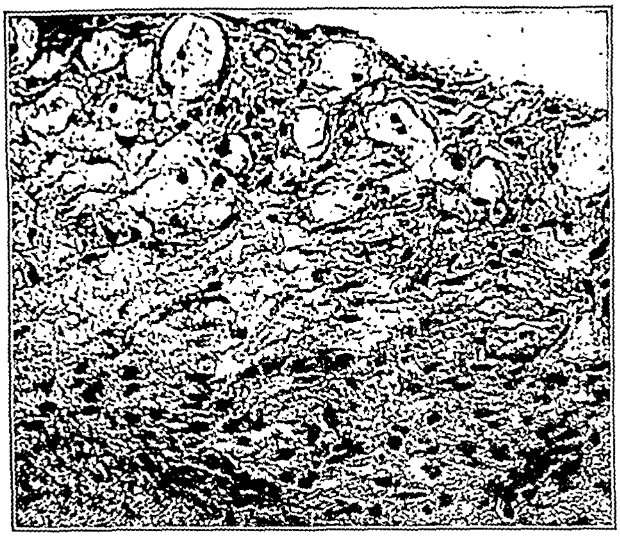

Fig. 6.—Inner surface of organized membrane attached to dura with the thin walled vessels through which transudate passes into cyst.

The line of force of the blow is probably in an anterior-posterior or posterior-anterior direction since the broad falx protects this region from lateral trauma.

Following the original hemorrhage there is organization along the inner dural surface with the formation of very thin walled vessels (fig. 6). From these thin walled vessels there is a continuous transudation producing the xanthochromatic fluid. Perhaps the increased intracranial pressure compresses the meningeal veins augmenting the transudation through passive congestion. From time to time a thin walled vessel may rupture. This accounts for the lamination of the membrane. The color of the fluid, which often varies on different punctures on the same side, is also determined in this way.

The membrane on the dura is chiefly supplied by the middle meningeal vessels. These increase greatly in size and are usually seen at operation to have two or three times the normal diameter. The great vascularity of a normal dura is seen in figure 6.

### TREATMENT

The outer membrane may be so thin as to be scarcely visible on the inner surface of the dura even though a great amount of fluid is present (case 1). We feel that this is the only type of case that might recover spontaneously or after repeated punctures of the fontanels. Rosenberg[4] states that 50 per cent of these infants die in the hospital, usually, however, of intercurrent infection. He traced fifteen out of thirty who left the hospital. Four died; of the eleven remaining, there were two idiots, three imbeciles, one severe neuropath, one stutterer, two bed wetters, one of whom had optic atrophy, and two were normal. Bronson Crothers[5] feels very pessimistic about complete spontaneous cures. Though our operative mortality is strikingly high, we feel that the poor progress reported by the most experienced observers justifies our position.

That recovery could take place without surgical intervention in such a condition as that presented by patient 5 seems out of the question. The inner membrane, which may be almost as tough as the dura, constricts the brain so tightly that expansion is impossible. After the membrane has been removed, the brain is seen to expand, provided the patient is not in deep shock.

Whether a subdural hematoma could regress spontaneously might be determined by examination of the membranes through a trephine opening. If seen to be very thin, conservative treatment might be tried. The thickness of the membrane does not determine the amount of fluid present or its rapidity of formation.

Our operative procedure is now as follows: If the case is bilateral, the subdural space opposite the side to be operated on is first tapped. This is to avoid subsequent pushing over of the brain with pressure on the brain stem by the fluid on the unoperated side after operation, when the intracranial pressure commences to reach the normal. We feel that three of our patients died as a result of this mechanism, for respiration ceased suddenly while the pulse continued for a short period. One should not wait until the operation has been completed before tapping the unoperated side, since the pressure then may be so low that very little fluid would be obtained.

A moderate sized osteoplastic flap is then turned down over the frontoparietal region. The dura is opened, leaving the base toward the occipital region. The middle meningeal vessels are clipped. The blue black gelatinous membrane is removed without an attempt being made to go too far beneath the dural incision. Following this, the depressed brain covered by a tough transparent or milky white membrane is seen. This is removed from the arachnoid as widely as possible, there being but slight danger from hemorrhage in this procedure. The dura is then closed and the bone flap replaced without making a decompressive opening. The scalp is sutured in two layers with silk. Facilities for immediate transfusion should be available.

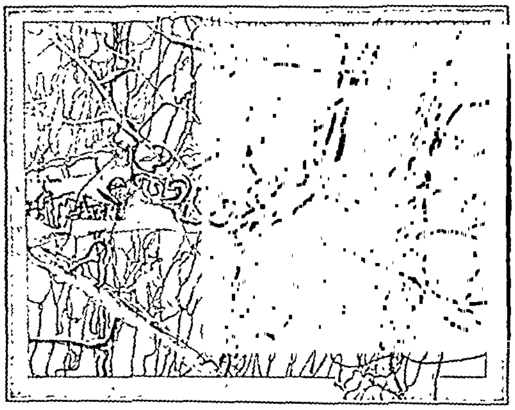

Fig. 7.—Normal dura, after R. A. Pfeifer.

### CONCLUSION

Subdural hematoma in infants is not a rare condition. In cases of apparent hydrocephalus, especially those presenting a normal facial expression and a dull percussion note over the parietal area, a subdural hematoma should be suspected and the fontanel punctured. Operation is justified in spite of the high mortality.

# SPONTANEOUS SUBARACHNOID HEMORRHAGE

W. R. OHLER, M.D.
AND
DAVID HURWITZ, M.D.
BOSTON

It is our belief that spontaneous subarachnoid hemorrhage occurs more frequently than is generally appreciated. This belief, together with the fact that the clinical picture is so striking and so easily recognized, prompts us to discuss briefly the subject, and to report concerning twenty-four cases entering the medical services of the Boston City Hospital in the eighteen months between July, 1929, and January, 1931.

## INCIDENCE

As an illustration of the frequency of subarachnoid hemorrhage, we have compared the incidence of this condition with that of cerebrovascular accidents of all types and subacute bacterial endocarditis during the same time period. The data are as follows: cerebrovascular accidents (all types), 353 cases; spontaneous subarachnoid hemorrhage, 24 cases; subacute bacterial endocarditis, 22 cases.

Thus, the incidence of subarachnoid hemorrhage is approximately one-fifteenth that of cerebrovascular accidents (including hemorrhages, thromboses) and about equal to that of subacute bacterial endocarditis, a much better known condition than subarachnoid hemorrhage.

## HISTORY

Subarachnoid hemorrhage was seldom recognized clinically before 1904. Most of the earlier cases were recognized only after a postmortem examination. Wilks [1] in 1859 described four cases of spontaneous subarachnoid hemorrhage, and Gintrac [2] in 1869 found only thirty-four cases recorded in the literature. It was after the introduction of lumbar puncture by Quincke [3] in 1891 that the clinical diagnosis of the condition could be made easily, especially from observations on the spinal fluid. Froin [4] in 1904 published a complete description of the fluid, its uniformly bloody character, the xanthochromia of the supernatant fluid, and the increase in depth of pigment on succeeding taps as the escaped blood became older.

Ehrenberg [5] in 1912 reported cases and described the condition in detail. Fearnsides [6] added forty-four cases and believed the hemorrhage due to aneurysms in younger people and to arterial degeneration in older people. The aneurysms in younger people he believed were the result of congenital defects of the media of the blood vessels; in fact, he emphasized the rarity of syphilis as a cause of intracranial aneurysm, since in the smaller arteries it causes an obliterative endarteritis rather than a weakening of the media.

McIver and Wilson [7] believed that acute infection produced meningeal hemorrhages by occlusion of many small vessels with infectious emboli and, in this way, weakening of the wall of the blood vessel. Mycotic aneurysms have also been described by Stengel and Wolferth.[8]

## ANATOMIC DESCRIPTION

The brain stem has three coverings or meninges. From without, inward, these are (1) the dura, (2) the arachnoid and (3) the pia, which is very vascular. Between the arachnoid and the pia is the cerebrospinal fluid. There are many trabeculae in this space.

Symonds [9] has pointed out that blood in the subarachnoid space may arise from one of the following four sources:

1. A subdural hemorrhage from lacerations of one of the large dural veins with rupture into the subarachnoid space.
2. A hemorrhage in a superficial part of the brain with rupture through the pia and into the subarachnoid space, cerebromeningeal hemorrhage.
3. A deep cortical hemorrhage with rupture into a ventricle and extension through the foramina of Luschka and Magendie into the subarachnoid space.
4. A rupture of one of the vessels lying in the subarachnoid space.

The first group is usually a result of traumatic laceration of the veins leading from the cerebral cortex to the great sinuses. Group 4 is the primary subarachnoid group. However, cases in groups 2 and 3 may present the typical picture of spontaneous subarachnoid hemorrhage with few or no signs of gross cerebral involvement. This is especially true of the patients entering in coma.

Symonds [9] emphasized the importance of the site of the hemorrhage in determining the rate of diffusion of the blood. If the hemorrhage occurs in the basal or pontile cistern, free diffusion is quickly accomplished. On the other hand, if it is in the ventricles, diffusion must occur through the narrow aqueduct of Sylvius, and there is a greater tendency toward localization. A superficial cerebral hemorrhage extending into the subarachnoid space is limited by the walls of the gyrus and the blood tends to gravitate to the base of the brain, and here also the rate of diffusion is slow.

## SYMPTOMS AND SIGNS

There is no condition in medicine that is more dramatic, more sudden, than subarachnoid hemorrhage. The patient is usually perfectly well until the sudden onset of headache. This strikes so suddenly and so intensely that some patients have described it as though "struck at the base of the skull" (Symonds). Vomiting, dizziness and coma may supervene in short order.

We have arranged the complete observations of our cases in table 1.

Some of the symptoms and signs are as follows:

*Onset.*—Of the twenty-four cases, histories were obtained in twenty. Of these, nineteen gave a story

of sudden onset. This is therefore a constant symptom. Onset usually occurs during exertion, as in playing games, tossing the baby in the air or straining at stool. The sudden onset helps to distinguish this condition from meningitis, in which the patient usually has a few hours of malaise, fever and slight headache.

*Headache.*—This symptom was present in sixteen of the twenty cases in which histories were obtained. The onset is usually sudden. The patients who go into coma usually remember later that a severe headache had preceded the loss of consciousness.

*Coma.*—Twenty-one of our twenty-four patients were brought into the hospital either in coma or in a stuporous state. Of the eleven stuporous patients, four died and seven recovered. Of the ten in deep coma, eight died and two recovered. It would seem, therefore, that the presence of coma adds to the gravity of the prognosis.

*Vomiting.*—This is a frequent symptom and was present in nine of our cases. It is probably due to the sudden increase of intracranial pressure. In six cases it was present at onset.

*Neurologic State.*—Of the twenty-four patients, seventeen could be roused. Six of these showed varying degrees of confusion. Histories were obtained for four of the six cases and indicated that the hemorrhage was of slightly longer standing than for the average case. Two of the six patients died. The other eleven patients were mentally clear. In meningitis, the patients in stupor or coma are more apt to be disoriented and irrational.

All but three of the twenty-two patients examined for the presence or absence of a stiff neck had this symptom. Stiff neck occurs early in the disease and is due to meningeal irritation. It is so constant that its presence in any patient should bring up the possibility of subarachnoid hemorrhage. The stiff neck may be mild at first and increase later. The Kernig sign is frequently present and is due to meningeal irritation.

None of the cases showed a large subretinal, usually single hemorrhage as described by Doubler and Marlow,[10] Hale-White [11] and Symonds. Two of our cases showed numerous fresh retinal hemorrhages. One of these patients had marked hypertension and a history of nephritis, and the hemorrhagic areas were flame-shaped. The other patient had hypertension (190 systolic) with no evidence of nephritis. Doubler and Marlow demonstrated that with subarachnoid hemorrhage the blood went down the optic sheaths and through the lamina cribrosa and ruptured through the retinal and hyaloid membrane. The patients with these large hemorrhages were associated in the cases described by the aforementioned writers with ruptured aneurysm of the internal carotid artery, usually near its termination.[12]

One patient had a paralysis of the left fourth nerve on entry. This nerve is fairly frequently involved. It occurred once in one of McIver and Wilson's cases [7] and in one of Richardson's cases.[13] Our patient showed no improvement in the paralysis while in the hospital, and complained of diplopia.

LABORATORY OBSERVATIONS

*Spinal Fluid.*—This is under increased pressure and is always bloody. It may vary in color from a pink to a dark red or a deep orange, depending on the degree and duration of the bleeding. One of Symonds' patients had a red blood cell count in the spinal fluid of over 3,000,000 per cubic millimeter. At first the white blood cells in the spinal fluid are proportional to the number of red blood cells. Then the number becomes slightly elevated, usually because of an increase in the polymorphonuclears; later, because of an increase in the lymphocytes. The supernatant fluid is faintly xanthochromic within from three to four hours after the onset and gradually becomes more xanthochromic. Usually the fluid is clear and colorless at the end of from ten days to two weeks. Care should be taken to distinguish bloody spinal fluid from a bloody tap (blood due to trauma of needle). The absence of clot, the uniformly bloody character of the fluid (when collected in the three tubes), and the xanthochromic supernatant fluid indicate a subarachnoid hemorrhage as against a bloody tap.

*Leukocytosis in the Blood.*—Of the twenty patients on whom white blood cell counts were done, eighteen had over 10,000 white blood cells per cubic millimeter. The average white count was 13,670 per cubic millimeter. One patient had over 20,000 white blood cells per cubic millimeter. The slight elevation in white blood cell count again confuses the condition with meningitis. There is no correlation between the white count and the outcome.

*Fever.*—The temperatures recorded in table 1 were the highest temperatures during the illness, excluding agonal rises. In the twenty-four cases, seventeen had temperatures of 99.5 F. or over. A temperature of 100 F. or over during the illness is the rule rather than the exception. Here again is a state of affairs which confuses the differentiation of meningitis from subarachnoid hemorrhage, although in subarachnoid hemorrhage the fever corresponds usually to the time of greatest hemolysis and absorption of pigments (first week).

*Albuminuria and Glycosuria.*—One case showed sugar and acetone in the urine with no previous history of diabetes and was at first thought to be a case of diabetic coma. However, the spinal fluid manifestations, the history of sudden onset, and the presence of severe headache established a diagnosis of subarachnoid hemorrhage. Most of our patients had albumin in the urine in slight amounts. Only two patients showed gross albuminuria and both of these had a few casts; one recovered and one died.

Claude Bernard, in his classic experiment, demonstrated that puncture of the fourth ventricle produces an increase in the volume of urine and often causes albuminuria as well as glycosuria.[14] Glycosuria and acidosis are known to occur as a result of hemorrhage in the region of the fourth ventricle. It is possible that such a mechanism is responsible for albuminuria in some of our cases.

Table 2 illustrates the similarities and differences of subarachnoid hemorrhage and meningitis.

The striking picture in subarachnoid hemorrhage is sudden onset, headache, stiff neck, bloody spinal fluid with no clots; in meningitis, gradual onset, stiff neck, cloudy spinal fluid with clots.

ASSOCIATED DISEASES

The most frequently associated condition in our series was hypertension. Of the twenty-three patients whose blood pressure was taken, twelve had a systolic blood pressure of 160 or over. Of these, seven had a systolic pressure of over 190. This association appears to be too frequent to be accidental. Hypertension plays a more important etiologic rôle in subarachnoid hemorrhage than is generally believed. A subarachnoid hemorrhage may result from the bursting of a congenital aneurysm under the strain of hypertension, or vascular changes may take place in the subarachnoid vessels which may then give way under the stress of hypertension. We believe that hypertension has a definite etiologic rôle, especially in older patients. None of our patients had syphilis: all had negative Kahn and Wassermann tests of the blood serum and spinal fluid.

Table 2.—*Comparison of Meningitis and Subarachnoid Hemorrhage*

| | Meningitis | Subarachnoid Hemorrhage |
|---|---|---|
| | Similarities | |
| Headache | Present | Present |
| Stupor | Usual | Usual |
| Vomiting | Frequent | Frequent |
| Stiff neck | Present | Present |
| Kernig's sign | Usual | Usual |
| Leukocytosis | Present | Present (less marked) |
| | Differences | |
| Onset | Gradual (at least several hours of malaise, etc.) | Sudden |
| Mental picture | Frequently irrational | Usually clear; occasionally irrational |
| Fever | Present and high | Often present and slight |
| Blood pressure | Normal | Frequently elevated |
| Eyegrounds | Negative (slight choking) | Occasionally large subhyaloid hemorrhage |
| Spinal fluid | Cloudy and clots | Bloody or xanthochromic; no clots |

Miscellaneous diseases associated with subarachnoid hemorrhage were: hypertension, twelve (seven died, five recovered); pulmonary tuberculosis (fibroid), one (recovered); diabetes with acidosis, one (died); post partum with hemorrhage, one (died), and bronchopneumonia, septic parotitis (complication), one (died).

Table 3.—*Ages, Recoveries and Deaths in Groups With and Without Associated Conditions*

| | | Associated with Other Conditions | | |
|---|---|---|---|---|
| | | Hypertension | | |
| Age | No Associated Disease | 160-189 | 190 | Others |
| Under 40 years (3 recoveries) (3 deaths) | | | | |
| Recoveries | 3 | 0 | 0 | 0 |
| Deaths | 0 | 0 | 2 | 1 |
| 40 to 60 years (7 recoveries) (4 deaths) | | | | |
| Recoveries | 2 | 4 | 0 | 1 |
| Deaths | 1 | 1 | 1 | 2 |
| Over 60 years (2 recoveries) (4 deaths) | | | | |
| Recoveries | 1 | 0 | 1 | 0 |
| Deaths | 1 | 0 | 3 | 0 |
| Total | | | | |
| Recoveries | 6 | 4 | 1 | 1 |
| Deaths | 1 | 1 | 6 | 3 |

Table 3 lists the ages, recoveries and deaths in groups with and without associated conditions. One case was not classified because the blood pressure was not recorded.

From this table it may be seen that all three deaths in the youngest group occurred in patients with definite complications, while single deaths occurred in each of the other groups without obvious associated disease (although it is quite likely that some arteriosclerosis was present in the patient in the group over 60 years of age). It is interesting that hypertension is important not only etiologically but prognostically. Of the seven patients with marked hypertension (over 190), six died.

### AGE

The average age for these patients was 50 years; the youngest patient was 17 years old. However, it must be noted that subarachnoid hemorrhage is by no means confined to persons of middle age and in this respect differs from other cerebral hemorrhages. There were several patients in the twenties. The average age of Neal's[15] patients was 27 and of Symonds',[9] 30, while the average of her arteriosclerotic group was 57. In the younger patients, congenital defect in the wall of the blood vessel seems to be the most logical explanation. Small aneurysms are commonly found in the brains of young people, and a rupture of one of these might cause a subarachnoid hemorrhage.

### PROGNOSIS

The mortality rate of the entire group was 50 per cent. The mortality rate of Neal's cases was 40 per cent. Of the seven patients with subarachnoid hemorrhage and without associated diseases, only one died. Ten out of the sixteen patients with associated diseases died. Of the seven cases with marked hypertension (over 190 systolic), all but one died (table 2).

It would seem that the prognosis in uncomplicated subarachnoid hemorrhage is good. The presence of associated diseases, especially of marked hypertension, adds considerably to the gravity of the prognosis.

### AUTOPSY OBSERVATIONS

There were five autopsies. It is interesting that the five patients were all in deep coma on arrival at the hospital; there were only six in deep coma who could not be aroused in the entire group, and all of these died. The autopsy observations demonstrate the difficulty in differentiating spontaneous subarachnoid hemorrhage from cerebromeningeal hemorrhage in cases admitted in deep coma. Only one of these was a typical case of spontaneous subarachnoid hemorrhage at the postmortem (case 19).[16] In this case there was a hemorrhage going over the lateral surface of the right frontal lobe. The origin of the hemorrhage could not be determined. Another had a superficial hemorrhage into the septum pellucidum with rupture into the ventricle and extension through the pia arachnoid of the brain stem. The other three were cases of cerebral hemorrhages with extension into the subarachnoid space and therefore really belong in the cerebromeningeal group. Aneurysms were not found in any of the postmortem examinations. Unfortunately, no autopsies were obtained on patients who were not in coma on entry.

We may say from these results that accurate diagnosis in patients in deep coma is impossible.

### TREATMENT

Symonds recommends lumbar punctures in the early stage only for increased pressure; otherwise a reduction in spinal fluid pressure might increase the tendency to bleed. He advises daily lumbar punctures later to remove the bloody fluid, the source of irritation to the meninges. Our patients all had daily lumbar punctures during the early stage. If the pressure was elevated, the fluid was withdrawn slowly until the pressure was lowered to from 100 to 150 mm. of water. Stiff neck and headache are sometimes quite persistent, the latter occasionally lasting from ten days to two weeks. We believe that daily lumbar puncture, removal of some of the fluid with reduction of the pressure, offers a marked relief. None of our patients showed any evidence of renewed bleeding in spite of the numerous lumbar punctures. We believe that this danger is minimized if the pressure is lowered very slowly. The danger is probably real in the few hours after the hemorrhage takes place. In the early stage, ice caps and salicylates may be used for the headache. Opiates are contraindicated, as in all cases of increased intracranial pressure, because of the danger of respiratory failure.

Usually the spinal fluid pressure becomes normal after the third or fourth lumbar tap. Persistently elevated pressure should bring up the possibility of a cerebral neoplasm as the underlying cause. This occurred in one case outside, proved at autopsy, not included in this group.

### CEREBROMENINGEAL HEMORRHAGES

Besides the twenty-four cases of clinical subarachnoid hemorrhage, we found seven cases classified as subarachnoid hemorrhage but with neurologic manifestations to indicate a definite amount of cerebral damage (table 1). All but one of these patients had a left hemiparesis or left hemiplegia, and one had twitching of the right arm. The youngest in the group was a 34 year old chronic alcoholic addict, and the average age of the group was 56, distinctly higher than the other group. The onset was sudden in all cases, and stiff neck was found in all the five cases recorded. Five of the seven patients had hypertension. The prognosis was apparently worse in this group since only two recovered, a mortality rate of about 70 per cent. There was one postmortem (case 1), which showed a large hemorrhage into the external nucleus with rupture through the pia and over the insula.

Outside of the neurologic observations, these cases are entirely similar to those of subarachnoid hemorrhage. The treatment is identical to that of spontaneous subarachnoid hemorrhage.

### SUMMARY AND CONCLUSIONS

1. Subarachnoid hemorrhage occurs much more frequently than is generally believed. We have gathered twenty-four cases in eighteen months between July, 1929, and January, 1931. This number is about one fifteenth the number of cases of cerebrovascular accidents and about equal to the number of cases of subacute bacterial endocarditis, a much better known condition.

2. Subarachnoid hemorrhage is a striking syndrome with sudden onset, usually with headache, occasionally vomiting, dizziness, stupor or coma, and rarely convulsions. Stiff neck, Kernig's sign, fever and slight leukocytosis serve to confuse it with meningitis.

3. Hypertension is present frequently (twelve out of twenty-four cases). Systolic blood pressure over 190 was present in seven patients, of whom six died. We believe that hypertension and arteriosclerosis play an important rôle etiologically and prognostically.

---

[15] Neal, Josephine B.: Spontaneous Meningeal Hemorrhage, J. A. M. A. 86: 6 (Jan. 2) 1926.

[16] The other four cases, although clinically cases of subarachnoid hemorrhage, therefore belong to the cerebromeningeal group.

4. The average age of our group was 50, the youngest being 17 and the oldest 75. This is higher than in Neal's and Symond's series.

5. Only one patient without an associated or a complicating disease died. Of the ten with an associated or a complicating disease, seven had hypertension (six over 190 systolic), one had diabetes with acidosis, one had bronchopneumonia and septic parotitis, and in one it occurred during the puerperium.

6. Five postmortems were done in the spontaneous subarachnoid group. These were all in patients brought into the hospital in deep coma. All but one showed cerebromeningeal hemorrhages. Of six patients entering in coma, all died. Coma adds to the gravity of the prognosis and obscures signs of gross cerebral damage.[17]

7. Seven cases of cerebromeningeal hemorrhage are briefly discussed. They may be differentiated clinically if they show evidence of brain injury (hemiplegia, Babinski reflex).

8. The treatment in these cases consisted of daily lumbar puncture until the spinal fluid pressure remained normal, and sedatives, ice caps, and the like for the headache.

# EFFECT OF AIR FILTRATION IN HAY FEVER AND POLLEN ASTHMA

B. Z. RAPPAPORT, M.D.
TELL NELSON, M.D.
AND
WILLIAM H. WELKER, Ph.D.
CHICAGO

This experiment was undertaken to determine the measure of relief that can be afforded the sufferer with uncomplicated hay fever by placing him in a room supplied with filtered air.

It seemed desirable also to learn whether comparative freedom from pollen irritation for a portion of the twenty-four hour period would establish reasonable personal efficiency for the remainder of that period. Pollen asthma was studied to determine the time element necessary to give relief. The efficiency of the commercial apparatus for pollen removal was studied.

## HISTORICAL

The earliest work on air filtration was that of Storm van Leeuwen,[1] who in 1924 described "miasm free" rooms used in the treatment of asthmatic patients. He developed a dust and miasm free chamber into which filtered air was pumped. Many of his asthmatic patients sleeping in such a room were partially relieved and could go about their work during the day with comfort, while others were entirely relieved of asthma by spending the night in the chamber. Since the earlier work, Storm van Leeuwen[2] has made a number of modifications to simplify his filtering apparatus.

In 1925, the Leopolds[3] at the University of Pennsylvania studied a group of cases under conditions in which not only the air was dust and pollen free but the temperature and humidity were controlled as well. Their work points to the possibility of controlling attacks in asthmatic patients sensitive to dust. The appliances used by both Storm van Leeuwen and the Leopolds were large and cumbersome, too costly to be easily adapted for use in a patient's home.

Later work with simplified mechanical construction was described by Cohen[4] in 1926. In his first filtering apparatus, the air taken through an opening in the window was delivered by a motor-driven fan through a filter of woven wool and cotton cloth, at the rate of from 140 to 180 cubic feet a minute. The room, which was closed but not hermetically sealed, was put under slightly positive pressure by the incoming current, so that the cracks about the doors and windows acted as outlets for the filtered air. Four ragweed sensitive cases are reported by Cohen in the preliminary study. A patient with very severe asthma required constant confinement in the room. Another patient with autumnal asthma was freed from acute symptoms after the first thirty-six hours of constant confinement. He then had to remain in the room most of the time for the next four days, after which he was able to remain outside for from eight to ten hours a day. A third patient, who had hay fever only, remained in the room eighteen hours a day for the first two days, after which he was able to be out from four to eight hours a day, depending on the pollen concentration outdoors. The fourth, also a nonasthmatic hay fever patient, was able to be outdoors eight hours a day.

Cohen[5] made a second study with an improved apparatus, which eliminated the spread of lint from the cotton and wool filter material. The machine used is reported as delivering 250 cubic feet of 99 per cent + pollen free air a minute. Such an apparatus was installed in each patient's bedroom just before the onset of the pollen season. The number of cases studied is not mentioned by the author. He reports that the number of hours necessary for the patient to be in pollen free air to obtain relief from symptoms varied with the pollen concentration outdoors. A shorter confinement period was required early and late in the season, while a much longer time was necessary at the height of the season. In midsummer, eight hours daily in the room was sufficient for mild cases, and from twelve to eighteen hours daily for severe cases. These observations were made on patients who began to use the filters before the development of hay fever symptoms. In asthma cases in which the patient came under observation after the symptoms had already developed, from two to seven days of confinement in filtered air was necessary for relief, after which the patients were able to be out for a part of the day with some comfort.

I. S. Kahn,[6] in discussing this report, mentions patients in Texas who require a much longer period of constant confinement to be cleared of asthma—twelve days for one, from one to two months for others, and as long as five months for one.

Peshkin and Beck,[7] in 1930, described a new and simplified portable filter which they state overcomes the objectional mechanical features of comparable air filters then in use. The essential difference is the filter screen, which is composed of several layers of a cellulose product held between a stiff open faced netting. The screen is corrugated and has a surface area of 8 square feet. The motor is equipped with three speeds, capable of producing 180, 250 and 400 cubic feet of air a minute. The apparatus is constructed so that filters can easily and quickly be replaced as often as required.

---

[17] Accurate differential diagnosis in comatose patients between cerebromeningeal and subarachnoid hemorrhage was impossible in our series.

### APPARATUS

The apparatus used in these experiments was an air filtration unit built by the American Air Filter Company. Two of these units were presented to the university for the conducting of these experiments. Each unit contained six filter forms with approximately 3 square feet of filter surface each. The edges of the filter forms rested on a felt covered frame on the top of the compartment in which was located the fan that propelled the air from outside the building into the room.

The filter material was of the cellulose type resembling ordinary filter paper but with a much larger porosity. The filters are sold on the market in varying thickness. Those used in our experiments were ten ply, and double sheets were used. Our experience with these filters in an apparatus used in connection with the drying of proteins led us to believe that the pollen granules could be filtered out of the air by their use. The pollen grains that made up the count in the experimental ward undoubtedly for the most part did not go through the filters but through small leaks in the machines. While such leaks are of no consequence in air filtration for the removal of dust in ventilating systems, they must be eliminated as far as possible in machines for the removal of pollen from the air. Even very low pollen counts have an undesirable effect on individuals who are highly sensitive to pollen. This fact must be fully appreciated by the manufacturers of commercial apparatus in order that the necessary efficiency may be attained.

The filter material was changed daily. The fan was shut down and the damper in the duct from the outside was closed. The forms were removed gently and placed on a sheet and taken to another room for the filter replacement. Our experience leads us to suggest that machines used for this purpose should be built so that there is no danger of pollen being carried into the machine beyond the filter sheets when the forms are being removed for the changing of the filters. In fact, a safer construction arrangement would be to have two sets of filters in series. If the first one is of such size that the velocity of the flow of air through it is very low, the efficiency can be still further increased. Our experimental eight bed ward had a cubical content of 7,500 cubic feet. The filter machines renewed this air approximately every six minutes.

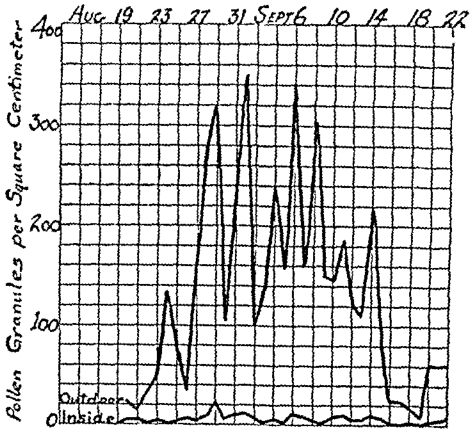

Fig. 1.—Pollen counts per square centimeter taken in filtered air room and outdoors.

### PROCEDURE

Pollen counts were made daily in the room, both directly in front of the outlet of each machine and at points distant from them. Counts were also made outdoors from a slide placed on a porch adjoining the room. The technic used in making pollen counts was that of Acquarone and Gay.[8] As pointed out by Duke,[9] the estimates of the pollen content of the outside air are not more than relatively accurate because of the many variable factors. In the room, however, most of these variable factors were not operative, the currents of air being about the same during the entire period of the experiment. The pollen counts in the room, however, are not an absolute index of the efficiency of the filtering apparatus. The counts varied little whether taken immediately in front of the machines, with the air currents sweeping directly over the slides, or when taken at a point away from direct currents.

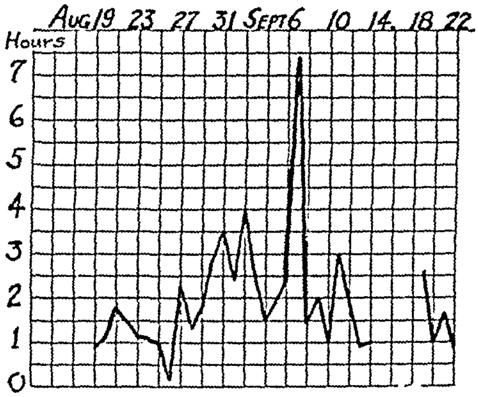

Fig. 2.—Average time required for maximum relief from hay fever symptoms on various days of the experiment.

The pollen counts in the room (chart 1) showed five or less pollen grains for each square centimeter on eighteen of the thirty-four days of the experimental period, ten or less on twenty-nine days, between ten and thirteen on five days, and a count of twenty-three on the day that a patient tampered with one of the machines. That night all the occupants in the room had moderate hay fever symptoms. While there was a slight rise of the pollen concentration in the room during the height of the pollen season, there was no tendency to follow closely the periodic rise and fall recorded outside the room. The absence of even approximate correspondence in the outdoor and indoor pollen curves renders it difficult to determine the precise filtration efficiency of the apparatus. Taken over the entire period, however, including the day it was tampered with, this was 95.4 per cent. During the major part of the experiment it was over 98 per cent. This approximates the 99 per cent plus filtering efficiency reported by Cohen with his apparatus.

The feeling of stuffiness complained of on most days was somewhat but not entirely relieved by increasing the air movements in the room. This was done by opening a transom leading to an adjoining hall and having an electric fan move the air in that direction. The discomfort was severe on the days when the temperature and humidity were higher than in either the adjoining ward or on the outside. The higher temperature in our filtered air ward may have been due to the fact that air was pumped into the room during the hottest periods of the day.

[9] Duke, W. W.: J. Allergy 2: 471 (Sept.) 1931.

One hundred and five patients were selected from a large group of applicants and admitted for study. Those who gave typical symptoms of autumnal hay fever either with or without asthma and with positive skin reactions to the ragweeds were chosen. They were divided into groups of eight, men alternating with women, each group for one week's observation. No case was therefore observed for more than seven days. The hay fever cases were usually kept under observation for only three or four days. They were admitted into the ward at 8 p. m. and permitted to leave at 10 a. m. Those with asthma were kept in the room during the entire period of observation except in special cases, when they were sent outdoors to observe the effect of exposure to pollen. All patients were interviewed morning and night, and full reports were made of the time required and degree of relief obtained, as well as the time of appearance and degree of symptoms experienced outside. This report, however, is based on sixty-six cases, the others being omitted either because the patient left after only one night of observation and the data obtained were insufficient, or because of intercurrent infections.

### OBSERVATIONS

The patients in this study can be classified into three groups: (1) uncomplicated hay fever cases, (2) combined hay fever and asthma cases, and (3) pollen asthma cases.

We observed thirty-five patients with uncomplicated hay fever of the autumnal type, spending 115 nights in the filtered air ward. The data compiled in the accompanying tables from the 115 nights gives the maximum relief obtained in time period and degree together with the degree of symptoms present in the morning, as well as the number of night attacks.

The average time required for maximum relief from hay fever symptoms on various days of the experiment is shown by chart 2.

Definite night attacks occurred in sixteen instances and consisted of hay fever symptoms only.

In 83.2 per cent of the uncomplicated hay fever cases studied without regard to the severity of the symptoms on entering the filtered air ward, relief of the symptoms was obtained either completely or moderately in three and one-half hours or less. In 7.5 per cent no relief was obtained, and in 13.9 per cent definite night attacks of hay fever occurred. In comparing the length of time necessary to obtain relief at different periods of the experiment, it was noted that in general the longest time required for relief occurred at the peaks of the pollen season. This bears out Cohen's[10] observations that the heavier the dose of pollen to which one is subjected, the longer time is required for relief of symptoms after entering the filtered air chamber. All the patients with uncomplicated hay fever reported that although symptoms as a rule appeared promptly on going outdoors, they believed that the degree of discomfort was less than they would have experienced had they not had from eight to ten hours of comparative relief during the preceding night. It was the opinion of most of the patients observed that their personal efficiency was definitely increased because of relief from pollen irritation during the night.

In our second group were ten patients showing combined symptoms of hay fever and asthma, either all the time or only part of the time. The average time for maximum relief from the hay fever symptoms was 1.2 hours, and the degree of relief was more complete than in the uncomplicated hay fever cases. The hay fever symptoms ceased as the asthma set in. Hay fever symptoms appeared very much sooner than did the asthma or asthmatic cough when the patient left the room. It was impossible to arrive at a definite average time for maximum relief of the asthma because most of the asthmatic attacks developed during the night, while the patients were in the room. Out of the thirty-two patient nights for these ten patients, only five night attacks of hay fever occurred, and these were of a mild nature, as compared to eleven night attacks of asthma, the majority severe enough to require epinephrine for relief. Several of these attacks were of a more severe nature than those which occurred during the day.

Twenty-one seasonal asthma cases sensitive to ragweed pollen were under observation, two from August 18 to August 22, the rest from September 2 to September 23. Two of the patients left after only one night of observation because of insufficient or no relief during this period. The others were observed for periods varying from two to seven days, the majority from four to seven days. All except two were kept in the room continuously except for the brief intervals necessary to attend to natural functions. The relief obtainable in these cases differed markedly from that observed in uncomplicated hay fever cases. All of them required epinephrine because of severe asthmatic attacks. Six of the twenty-one patients were observed for seven days. Of these, two required epinephrine for two days, two for three days, and two for the full seven days. The required dosage varied from 8 minims (0.5 cc.) several times a day and during the night in mild cases to 15 minims (1 cc.) every two to three hours in the severe cases. The dyspnea became less acute in all except two cases after the patients were in the ward twenty-four hours. These two required four days before feeling relieved from acute distress. Humidity seemed to be an important factor in all the asthma cases observed. The symptoms were much more severe during and following rainy days.

---

[10] Cohen (footnote 5, third reference).

The objective manifestations of prolonged expiration and wheezing cleared completely only in two cases: one after five days in the ward, the other after three days in the ward. Neither of these patients had any asthma on reporting back twenty-four hours after their discharge. In the other nineteen cases there was still wheezing on leaving, four of these after seven days of observation in the filtered air.

Four of the patients who had been relieved completely of all subjective asthma and in whom there was only slight wheezing were permitted to go outdoors. All developed asthmatic attacks from one-half hour to one hour after leaving the room. These observations agree with those of Cohen,[10] who reported that relief for pollen asthma is not so readily obtained as for uncomplicated hay fever.

### SUMMARY AND COMMENT

Thirty-five patients with uncomplicated autumnal hay fever, protected from pollen during twelve to fourteen hours a day, were in most cases made comfortable in from half an hour to three hours after entering the room with filtered air. The degree of relief was moderate to marked in the majority of cases. A large proportion of patients had recurrences of symptoms of a mild nature while in the room either during the night or on awaking in the morning. All cases manifested symptoms promptly on exposure to unfiltered air. Ten patients with hay fever and asthma and twenty-one with pollen asthma were observed for periods up to seven days. Relief from hay fever symptoms was as prompt as in the first group. Relief from asthma was obtained only after constant confinement of from one to four days. Night attacks of asthma were more frequent in these groups, and of a severer nature than the night attacks of hay fever in the hay fever patients. In spite of constant confinement in filtered air, most pollen sensitive asthmatic patients require epinephrine for relief of acute attacks. It is our impression that in many patients hay fever asthma is not caused by the offending pollen alone. The individuals in this group were exposed to much more pollen during the first few weeks of the hay fever season than was present in the room, without any symptoms of asthma. The persistence of symptoms in spite of protection from pollen suggests either the prolonged action of pollen previously inhaled or the presence of some additional cause for their asthma. The bogginess of the nasal and bronchial mucosa after several weeks of irritation from pollen offers an excellent ground for bacterial growth. It is our belief that a low grade infection of the upper respiratory tract is as much responsible for the asthma in these cases as irritation from pollen.

Considerable discomfort from heat and humidity was experienced by those confined to the room. This may be lessened by increasing the air movement in the room or by shutting off the machine during the daytime for those patients able to be outdoors part of the time.

We expect to continue studies along these lines during the next ragweed pollen season, with additional types of air filters and with air cooling devices.

### CONCLUSIONS

1. Air filtration that removes most of the pollen will relieve symptoms of hay fever. It is particularly valuable in those cases not benefited by the usual methods of treatment.

2. Cases of pollen asthma respond slowly to filtered air treatment. In most cases only partial relief was obtained, even after seven days' occupation of the ward. All asthmatic patients studied were decidedly more comfortable in filtered air.

3. Recurrence of symptoms was prompt on exposure to pollen, but in uncomplicated hay fever cases the personal efficiency was increased because of relief from pollen irritation during the eight to ten hours in the filtered air ward.

4. From our results we conclude that it will be possible to increase the efficiency of the commercial air filter for the removal of pollen through some minor mechanical changes.

# THE USE AND ABUSE OF DRUGS IN ASTHMA

MILTON B. COHEN, M.D.
AND
JACK A. RUDOLPH, M.D.
CLEVELAND

The emphasis that has been given to the study of asthmatic patients by immunologic methods has resulted in so many advances in our knowledge of handling these patients that careful study and cooperation by physician and patient leads to control of the seizures and prevention of their recurrence in the majority.

While there are no drugs that will cure the allergic state or even prevent an attack when the allergic body contacts with a large dose of the specific allergen, various remedies do assist in the control of individual attacks and should be used until the attacks are prevented by specific means. Some of these remedies, such as the iodides, the inhalation of smoke from nitro papers and stramonium leaves, the antispasmodics and opiates, have been in use for years. Hyde Salter[1] given an excellent account of their use in his classic work on asthma, and practically nothing can be added to his observations about most of them. Epinephrine, which has been in use for the past twenty years, and ephedrine, introduced recently, have been widely used, and there are many articles dealing with their pharmacology and clinical application.

Most of the patients whom we see have had various ones of these remedies used with good effect. In some, however, their use had been followed by unfavorable results and in a few by death. It has seemed to us, therefore, that it might be well to review briefly the actions of these drugs, their field of clinical usefulness and their dangers, and to point out some details of the methods of their administrations.

### EPINEPHRINE

Epinephrine is the active principle of the medulla of the suprarenal gland. Its action consists in a stimulation of the peripheral end organs of the sympathetic nervous system. It is poorly absorbed from mucous membrane surfaces and slowly absorbed after intramuscular or subcutaneous injection but has an immediate action following its intravenous administration. The action is of but short duration, since epinephrine leaves the blood stream rapidly and is soon oxidized. Its effect can be maintained by continuous intravenous administration of small amounts. Solutions are unstable unless a preservative is added. The effect of this drug

---

Read before the Academy of Medicine of Cleveland, Feb. 19, 1932.

From the Asthma and Hay Fever Clinic of the Asthma, Hay Fever and Allergy Foundation.

[1] Salter, H. H.: Asthma: Its Pathology and Treatment, first American from the last English edition, New York, William Wood & Co., 1882.

on a patient in an attack of asthma is startling when observed for the first time. Within from five to fifteen minutes after the subcutaneous injection of a suitable dose the paroxysm begins to subside, and usually within thirty minutes it has completely disappeared. The effect following subcutaneous administration lasts for from thirty minutes to two hours. This prolonged effect, several times as lasting as that following intravenous administration, can be explained by the fact of the slow and more or less continuous absorption from the peripheral area, giving the effect of the continuous intravenous administration of minute amounts. The therapeutically active amount for the relief of asthma, therefore, is extremely small. The therapeutic dose is much smaller than that usually recommended. Most textbooks give the dose as from 0.5 to 1.0 cc. (8 to 15 minims) of the 1:1,000 solution, and many physicians give the contents of one ampule (1 cc. of 1:1,000 solution) as a routine. Such doses are very dangerous; they cause attacks of palpitation, cardiac irregularity, intense throbbing headache, vomiting, intense excitability, tremor, blanching of the skin and extreme weakness. These epinephrine reactions are unnecessary, as the full therapeutic effect on asthma can be obtained by small doses. It is a safe rule to give from 0.2 to 0.4 cc. of the 1:1,000 solution (3 to 6 minims) subcutaneously. The attack will subside in most cases in a few minutes; if it does not, the dose should be repeated in twenty minutes.

Patients having severe attacks will have a recurrence of symptoms in a few hours. For these it is well to observe the frequency of recurrence and to administer a dose of epinephrine just before the next attack begins or on its inception. Often the administration of 0.3 cc. of the 1:1,000 solution every three or four hours, day and night, will prevent the symptoms completely, and less of the drug will be needed than if one waits for the attack to be full blown before giving it. For this reason all asthmatic patients should be taught to administer epinephrine to themselves. A glass syringe should be used, and it should be boiled and not sterilized by alcohol, since the small amount of alcohol in the syringe may destroy the drug. The solution used must be crystal clear and colorless. The slightest tinge of color indicates that some of the potency is lost, and when there is obvious pink color the solution is useless. This point is made because so much of the epinephrine solution on drug store shelves and in physicians' bags, especially the ampules, since these contain no preservative, is no longer potent. This explains why some physicians are disappointed with the drug therapeutically and also why doses of 1 cc. are so often given without dangerous reactions.

When given properly, epinephrine is the most valuable remedy that we possess for relief of the acute asthmatic paroxysm.

### EPHEDRINE

Ephedrine is the alkaloid of the plant ma huang, which has been used as medicine by the Chinese for centuries. Pharmacologically, its effects on the sympathetic nervous system are similar to those of epinephrine, but the effect is more lasting. It is readily absorbed from the gastro-intestinal tract and its full therapeutic effect can be obtained by oral administration. It has been used in the treatment of patients with asthma since its introduction in 1924 by Chen and Schmidt,[2] but a large experience with it has proved it of less value than was expected from its action in animals. Except in rare instances, a full therapeutic dose will not relieve a severe paroxysm of asthma. It is helpful in continuous doses in preventing mild seizures and does control the wheezing of the mild asthmatic state very well. It is best administered as the hydrochloride or sulphate in doses of from 25 to 65 mg. The effect lasts from four to six hours.

Ephedrine is poorly tolerated by most patients when given alone. It produces wakefulness, bad dreams during sleep, marked weakness, nausea, sweating and, in some patients, cardiac irregularity. The cerebral symptoms can be controlled by administering a small dose of some hypnotic with each dose of ephedrine. It is our custom to prescribe from 5 to 10 mg. of amytal with each 50 mg. of ephedrine hydrochloride. This dose can be given four times daily, evenly spaced between the hours of arising and retiring. Extra doses are useless if an attack supervenes. Epinephrine should be given for such an attack.

Ephedrine, like all alkaloids, is soluble in oils. A 1 per cent solution in oil is useful for nasal use in hay fever but has no place in the treatment of the asthmatic paroxysm.

### OPIUM

Some form of opium is recommended in asthma by almost all writers on medical subjects. Morphine is the drug advised by the majority. It is used to dull the excitement and fears of the patient so as to enable him to use his respiratory muscles to the best advantage and because it is supposed to produce bronchiolar relaxation in certain doses. However, when one reviews the pharmacologic action of the drug, one finds that its effects on the bronchiolar musculature are by no means constant and that narrowing of their lumen may follow its administration. Clinical experience with the drug in asthma shows it to be dangerous. For several years we have been asking various allergists their opinions as to the usefulness of opium in asthma, and we have been struck by the almost unanimous opinion that its use is unnecessary, frequently harmful and occasionally fatal. Hyde Salter[1] expressed his opinion as follows:

> To opium in asthma, I have myself a great objection. I do not mean to impugn the correctness of those who profess to have seen benefit derived from it; all I would say is, that I am not certain I have ever seen it do good, that I have often seen it do harm, and that I should have antecedently expected, from its known physiological action, that it would be prejudicial, and tend to increase the very condition for which it is given.

He then discusses the central effects of opium, considers them harmful and then says:

> But, beyond this, opium seems to have a specific tendency to excite involuntary muscular action and induce a temporary spasm. . . . But I would not let any theoretical objection run counter to clinical evidence; and if experience said "give opium," no theory should prevent my recommending it. My own experience, however, coincides with these objections; and *I am disposed to think that the frequency with which it is given in asthma depends upon an unthinking following of routine and a want of close and exact observation.*

Death in an acute attack of asthma is rare, but we have observed it on six occasions. In five cases, death followed within a few hours after the administration of morphine and in one case following the use of codeine. In none of these patients was there any clinical evidence of cardiac disease or other organic pathologic condition sufficient to cause death.

In all there was an increase in the asthmatic symptoms following the drug. The respiration became progressively more labored, and the patients died respiratory deaths quite comparable to those seen in strangulation. In two cases examined post mortem, the entire bronchial tree was filled with mucous exudate so tenacious that it was difficult to pull it away from the bronchial wall. These patients had been strangled by their own mucous secretion.

---

[2] Chen, K. K., and Schmidt, C. F.: Ephedrine, Proc. Soc. Exper. Biol. & Med. **21**: 351, 1924.

There are several possible explanations for these bad effects; the first is that morphine depresses the respiratory center and makes the respiration more shallow; the second, that the abolition of the cough reflex makes it more difficult for the patient to expel the mucus plugs from the bronchial tree, and the third, that opiates are themselves hive producing. Morphine, codeine and other opium derivatives produce wheals when injected into the skin. All individuals are susceptible, but some get very marked reactions following their intradermal injection. Many patients have itching following the hypodermic injection of morphine. It is quite probable that in those asthmatic patients with an idiosyncrasy to opium there is produced by the morphine or codeine a hive reaction in the bronchial tree, which is added to the reaction already present because of the attack. These theories are being studied experimentally to determine whether they explain the phenomena observed. That opiates are contraindicated in asthmatic patients because of their bad effects cannot be doubted by any one with sufficient experience with these patients.

### BELLADONNA, STRAMONIUM, HYOSCYAMUS

The effects of belladonna, stramonium and hyoscyamus depend on their atropine content. Atropine paralyzes the innervation of the bronchial muscles and glands, causing bronchial dilatation and lessening of the mucous secretion. The best effects are obtained when the drug is inhaled. This can best be accomplished by inhaling the smoke produced by burning powder composed of powdered stramonium, 1 Gm., and potassium nitrate, 2 Gm., or the smoking of a stramonium cigaret. The smoke of 1 Gm. of stramonium leaves is said to contain from 0.3 to 0.5 mg. of atropine. Most of the asthma cigarets and powders on the market are similar to the formula given, although some contain tobacco, lobelia, anise or other volatile substances. The inhalation of these smokes is followed in a few minutes by cough and expectoration of the mucous plugs which were obstructing the bronchial tree. In some patients the relief is prompt and satisfactory; in others apparently similar clinically, no relief is obtained. Atropine is not nearly so useful when administered by other routes, since it is frequently necessary to give toxic amounts in order to relieve an asthmatic attack, and this can be done much better by epinephrine.

### IODIDES, TOBACCO, LOBELIA

Iodides, tobacco and lobelia assist in the relief of mild paroxysms of asthma by their thinning effect on the bronchial mucus. The iodides are excreted directly in the bronchial mucus; tobacco and lobelia produce thinning by their nauseating effect. Iodides are often of use between acute paroxysms, particularly in asthmatic patients with secondary bronchitis. Since the iodides are absorbed from the gastro-intestinal tract with amazing rapidity, their full effect is obtained by oral administration and there is no justification for their administration by the intravenous route.

### CALCIUM

Calcium has been used in asthma because of its alleged antiedemic action in diminishing cellular permeability. Recently it has been shown that this action cannot be demonstrated experimentally,[3] and studies by Ramirez,[4] by Criep and McElroy [5] and by Cohen and Rudolph [6] have shown that there is no clinical effect when calcium is administered to asthmatic patients. It should be excluded from the list of remedies for asthma since it will not benefit the patient in an acute attack and has no influence on the recurrence of attacks.

Many other drugs have been used from time to time with supposedly good results. Most of these good results will not stand critical analysis, and the time allotted for this presentation does not permit their discussion.

### SUMMARY

*Before the attacks of asthma are prevented by proper study and treatment, it is necessary to use drugs to ameliorate the symptoms.*

*Epinephrine in small doses is the remedy of choice. Ephedrine has a smaller but definite field of usefulness. Opium in all forms is contraindicated because of its dangers. Iodides, if used, should be given by mouth and not intravenously.*

# LAXATIVE EFFECTS OF WHEAT BRAN AND "WASHED BRAN" IN HEALTHY MEN

## A COMPARATIVE STUDY

GEORGE R. COWGILL, Ph.D.
AND
WILLIAM E. ANDERSON, B.S., M.A.
NEW HAVEN, CONN.

The importance of ingestion of a reasonable amount of food "roughage" for the maintenance of satisfactory intestinal motility is widely appreciated. It is quite generally recognized that wheat bran contains a relatively large amount of indigestible material, notably cellulose. Knowledge of these facts has resulted in a considerable use by human beings of bran as a source of food roughage. Extreme views regarding such use have been expressed in the literature. Kellogg [1] is one of those who attribute numerous ills to constipation and therefore advocate the ingestion of large amounts of various sources of "indigestible residue," including bran, as a corrective and preventive measure. Alvarez [2] has challenged this view, and, as evidence for his position, has cited the results of a questionnaire circulated among physicians concerning the therapeutic use of bran. It may be questioned whether such a method of approach to the problem as Alvarez has employed is adequate or even suited. A more logical plan seems to be to test bran for laxative power on human beings subsisting on suitable, carefully controlled diets. The

The expenses of this research were in part defrayed by a grant from the General Foods Corporation, New York.

Wheat bran, extracted twenty hours at room temperature with 0.2 per cent hydrochloric acid to remove phytin and other substances, is called washed bran in this paper.

[1] Kellogg, J. H.: The New Dietetics, Battle Creek, Mich., Modern Medicine Publishing Company, 1921.

[2] Alvarez, W. C.: Minnesota Med. **14:** 296 (April) 1931.

present paper is a report of such experiments conducted on healthy men.

Early recognition of the laxative value of bran in cattle, coupled with the knowledge that bran contains phytin, a phosphorus-yielding organic complex easily removed by washing with weak acid, led Jordan, Patten and Hart[3] to try the experiment of feeding to cattle a bran that had been treated with weak acid to remove the phytin; constipation definitely resulted and was relieved by the administration of the natural bran. The conclusion was drawn that the laxative power of bran is due predominantly to the phytin which it contains. Tests of salts of phytin performed on other species of animals[4] failed to confirm this. Williams[5] experimented on the dog and observed no difference between whole bran and the phytin-extracted product with respect to laxative power. It is possible that the observations of Jordan, Patten and Hart on cattle are in some way related to the fact that this species possesses that unique organ, the ruminant stomach. Then it should be borne in mind that treatment of bran with weak acid results in the extraction not only of phytin but also of inorganic phosphates and other substances, and that the absence of these other materials rather than of the phytin may have been responsible for the effects observed in the ruminant. The results suggest that, when an endeavor is made to evaluate bran as a laxative for man, it is pertinent to inquire whether the phytin which it contains contributes in any way to enhance the effect due to the indigestible cellulose also present. When this question is answered, it will be possible to say whether bran is to be regarded as having a somewhat unique value as a laxative or whether it is to be classified among foods simply on the basis of its content of indigestible residue. The experiments reported in this paper represent attempts to answer this question as it relates to the human species.

## CRITERIA OF LAXATIVE ACTION

In the study of laxation,[6] one is confronted at the outset by difficulty in the selection of suitable criteria of laxative action. Among the indexes that suggest themselves are: (1) subjective impressions of the persons concerning the complete and satisfactory character of elimination; (2) the amount of intestinal contents evacuated under the test conditions; (3) the water content of the stools, a large amount of water being indicative of only a brief stay of fecal material in the colon with consequent failure of absorption of water, and a low water content pointing to the opposite condition; (4) the time of passage of material through the alimentary tract; (5) the number of defecations in a unit of time, or laxation rate, and (6) the amount of indigestible substance, fiber, for example, present in the stool and the relation of this to the quantity ingested. In presenting the results of this investigation, each of these possible criteria will be considered and discussed.

The number of defecations in a unit of time—laxation rate—would seem to be the most logical objective indication of the extent to which laxation is taking place. The observations of Williams[5] on dogs indicate that this assumption is not without foundation. In the case of human beings, however, the mere record of the number of defecations may prove inadequate, because of the effect of habit or "conditioning" of the defecation reflex as the result of a highly organized social life.

Studies of the defecation reflex in animals indicate that it involves primarily a purely intrinsic nervous mechanism, which, however, may be influenced by nerve impulses from the brain. As an illustration of this, one may cite the case of Goltz's[7] dog in which the spinal cord had been severed in the lower thoracic region; this animal, nevertheless, performed the defecation act in normal fashion. In later experiments by Goltz, in which the entire spinal cord was removed except in the neck and upper thoracic region, the animal, after recovery from the operation, had a normal movement once or twice a day, indicating that the rectum and lower bowels acted by virtue of their own intrinsic mechanism. What are the stimuli capable of arousing the defecation reflex in such an animal? At the present time they are little understood. It is conceivable that one or more of the following factors may play a rôle: (1) the amount or bulk of the material present in the lower bowel ready for elimination; (2) the actual pressure or distention that this mass may exert on the colon or rectal wall; (3) the area of intestinal wall that it may stimulate by contact, and (4) chemical stimulation of the colonic wall by substances in the fecal mass. Just how these factors may be studied and measured is by no means clear. In the case of human beings, who have developed the habit of defecating at fairly definite times, the execution of the defecation reflex obviously does not depend solely on the influence of such factors.

## GENERAL PLAN OF EXPERIMENT

The plan adopted for this investigation consisted in having healthy men subsist first of all on a carefully selected basal ration, the laxative effect of which was known by having been recorded during a preliminary period of observation, and then on the same ration supplemented by a selected test amount of whole or washed bran. The comparison of these bran products was made on a fiber-equivalent basis.

In the preliminary studies a basal diet having what might be regarded as an average or normal fiber content was used; under such dietary conditions the laxative power of bran was not readily demonstrable. Another type of experimental ration was then devised and employed; namely, one the continued use of which was associated with a mild degree of constipation, as represented by defecation once a day. Finally, tests of the bran products were made by means of a diet that was markedly constipating in its effects. Three illustrative diets representative of these different experimental conditions and ingested by the same person are shown in table 1.

The foods were selected in such a way as to give a combination both qualitatively and quantitatively suitable for the respective persons. For example, orange juice was provided in order to insure an adequate supply of the heat-labile antiscorbutic vitamin.

[6] In the writing of this paper the question arose as to the correct use of the word laxation. Investigation revealed that this word is not listed in the two standard medical dictionaries that were consulted; nor was it found in the Winston "Simplified Dictionary." In Webster's New International Dictionary (page 1223) laxation is defined as "the act of loosening, slacking or relaxing, or state of being loosened, slackened or relaxed." The definition given in the Funk and Wagnalls New Standard Dictionary of the English Language is essentially the same. It will be noticed in the definition cited that there is no specific reference to the alimentary tract. In this paper the writers have decided to use the word laxation to signify the act of loosening the bowels as well as the state or condition or degree of loosening characteristic of the bowels.

When the experimental diet had been selected in each case, a capsule containing either charcoal or carmine was taken by the person in order to differentiate the stool formed from the residue of the meal ingested at the time the "marker" was taken. This technic for identifying the stools was used at the beginning of each experimental period. Each stool was weighed immediately on passage and then allowed to dry in a current of warm air. All the specimens evacuated during a given experimental period were then combined and the entire mass was weighed, ground to a degree of fineness suitable for analytic work, and then analyzed for residual moisture, fiber and mineral substances. In each period not only the number of laxations was recorded but also the time of passage and the subjective sensations of each individual with respect to difficulty of bowel movement, satisfactory evacuation, and the like.

In general, foods poor in fiber content were selected. Each food was analyzed for crude fiber,[8] mineral materials and moisture content, thus making it possible to estimate for each person the total intake, particularly of fiber and inorganic substances, for comparison with the amounts evacuated from the intestinal canal.

It is possible that the degree of hydration of the individual exerts some influence on laxation. Therefore, each person measured the volume of fluid taken daily during the preliminary period, when the exact details of the basal ration were being determined, and, on the basis of these observed quantities, selected that volume which should be taken daily, and thereafter drank that amount regularly. In this way each person conformed to his own desirable standard with respect to fluid intake.

## RESULTS

Part 1.—*Preliminary Experiments.*—Five healthy men served as subjects for the initial feeding trials. The experimental periods were four days long. Whole bran and two bran products were tested. During these preliminary periods, it will be recalled, the basal diet contained what was regarded as an average or normal content of fiber (table 1, part 1).

The following observations were made: On the basis of subjective impressions, four of the five persons on experiment noted no essential difference between the control and the experimental period. It was found that the laxation rates—number of defecations per day—were consistently high, the average for all periods being twice a day. When the data for the amount of material eliminated per day were studied, however, it was found that in thirteen out of fifteen instances the addition to the basal diet of bran or either of the test bran products resulted in an increased elimination of fecal material. In a few cases the increase was large.

These results raised several important questions: Was the failure to obtain a subjective impression of laxative effect related to the high laxation rate which prevailed when the individuals subsisted on the basal ration alone? Was it not likely that the person failed to notice the moderate increase in laxation, which occurred, as shown by the data for amount of material eliminated, because the rate was already high enough to give the feeling that laxation was satisfactory? This suggested that the different criteria of laxative action discussed in a preceding section may differ in their applicability to various conditions. There was also the possibility that the experimental periods in this preliminary study were too short; that four days is not enough to avoid a hang-over effect of a given period on the succeeding one.

Another point should be mentioned. Let it be assumed that the laxative action of the diet is due primarily, if not solely, to its content of indigestible material, of which fiber may be taken as the representative. Suppose that the amount of fiber already present in the diet and exerting a laxative action is great enough to bring about a high laxation rate. Under these conditions, then, it is quite possible that the quantity of additional fiber required in order to bring about a significant increase in the rate of laxation may be much greater relatively than that needed when the defecation rate is low enough to be interpreted subjectively as constipation. In other words, the basal diet used in these preliminary trials may have had too much fiber in it to allow satisfactory subjective demonstration of increased laxation due to ingestion of bran or other test material. This explanation of the preliminary observations is supported by the observations of Thorup and Carlson,[9] who investigated the influence of yeast on the alimentary rate. In their study the greatest changes in the intestinal rate resulting from ingestion of yeast occurred in those individuals who exhibited, as their "normal," rates below the average.

In the light of these considerations it was deemed advisable to repeat the study of the laxative action of bran by making observations on individuals subsisting on a basal diet definitely constipating in its effect and by extending the observations over much longer periods than were employed in the preliminary trials. Some difficulty arose in deciding not only as to the proper duration of the periods but also as to how severe the constipation induced by the experimental ration should be. It was decided to experiment with a basal diet which allowed a defecation rate of once a day and which was interpreted subjectively as "a rather unsatisfactory condition" or "mild constipation." It was believed that such a condition could be endured without injury by the persons acting as the subjects for the investigation for experimental periods of fourteen days' duration. The experiments carried out in accordance with this plan are described in part 2.

Part 2.—*A Comparative Study of the Laxative Effects of Whole Bran and Washed Bran in Healthy Men Exhibiting a Mild Degree of Constipation.*—Experimental Details: Five healthy men served as the subjects for these experiments. The experimental periods were of fourteen days' duration in the case of four individuals and of ten days' for the fifth person.

An effort was made to select a basal diet distinctly lower in fiber content than that used in the preliminary studies. Because the total time of subsistence on the basal ration with and without supplement of test product was planned to range from at least four to eight weeks, each person experimented by ingesting varying amounts of the selected foods over periods of from ten days to two weeks in an endeavor to find a daily ration that he would be able to eat for a long period without subjective or other difficulty and which at the same time would meet the requirements of the research. When the experimental diet had been selected in each case, the "marker" of charcoal or carmine was taken to differentiate the stool formed from the residue of the meal ingested at that time, and the test period was formally begun.

The amount of fiber present in the new diet was less than that contained in the ration used in the preliminary study by about 1 Gm. The amount of water taken daily was carefully standardized in the manner previously described. In comparing washed bran with the natural product, fiber-equivalent quantities were used.

Subjective Impressions as a Criterion of Laxation: In every case the individuals reported that while on the basal diet only they felt that the bowels were unmistakably constipated although defecating once every day. The constipation was not of severe degree but was sufficient to be noticed. Frequently the evacuations were not satisfactory; there was the impression that emptying was incomplete. The urge to defecate, when it did occur, was not as pronounced as formerly. In contrast to this it was noticed that, when either the whole or the washed bran was taken, the urge to defecate was unmistakable at practically all times and could not be disregarded. Moreover, there was the feeling that the evacuation was fairly complete. The stools were more bulky. It was obvious that the ingestion of the whole bran or the washed product resulted in the production of a larger stool. So far as the subjective sensations were concerned, there seemed to be little or no difference in the physiologic effects of the two products tested.

* From 1 to 1½ ounces of whole bran daily and the fiber equivalents of washed bran were the quantities used in test periods 2 and 4, respectively.

† Ten day periods.

Laxation Rate as a Criterion of Laxative Effects: Table 2 presents the data concerning the laxation rates that prevailed in the persons on these experiments. It will be observed that, after adding either 1 ounce of whole bran or its fiber equivalent of washed bran to the diet, only one person (S. A. P.) showed a pronounced increase in laxation rate over that of the basal periods. In this case the whole bran proved to be slightly superior to the washed product, if one chooses to regard the difference between eighteen and twenty-one defecations occurring in as long a period as fourteen days as a significant one. This is questionable. In the other cases there was only a slightly increased laxation rate in the test periods as compared with the controls. The subjective impressions of the persons, nevertheless, support the view that these test substances did exert laxative action.

Amount of Intestinal Contents Evacuated: The ingestion of either whole or washed bran resulted in daily evacuation of an increased amount of material. The data are presented in table 3. In view of the fact that S. A. P. showed an increased laxation rate when given bran (table 2), it became of interest to determine the average amount of material eliminated at each defecation. Data relative thereto have been incorporated in table 3.

In the case of S. A. P. (table 3) the amounts of material eliminated per day were approximately the same as those evacuated by the other persons. However, S. A. P., unlike the rest of the group, evidently could not retain such large amounts of fecal matter in the lower bowel without undue stimulation of the defecation reflex. The recent observations of Hines, Lueth and Ivy[10] on the contractions of the rectum and their relation to the defecation urge indicate that human beings show some variation with respect to their sensitivity to pressure within the rectum and the contractions of this organ. The increase in the defecation rate in the case of S. A. P., associated with average elimination of a relatively smaller stool, probably finds its explanation in such observations as those of Hines, Lueth and Ivy just cited.

In view of these positive observations with respect to the subjective criteria of laxative action and the increased amount of material eliminated, but negative result with respect to effect on laxation rate, further experiments with individuals exhibiting a constipation even more severe in degree were deemed advisable. After completing the experiments just reported,

W. E. A. experimented further in an endeavor, first, to determine how best to alter the basal ration so as to produce a more constipated condition in himself and, secondly, to test the effect of ingestion of bran on the condition thus produced. The basal diet used previously (part 1) is shown in table 1. As a result of the elimination of potatoes from this ration and the reduction of the daily intake of bananas from 350 Gm. to 200 Gm., marked intestinal stasis developed. When this had prevailed for eight days, 30 Gm. of whole bran was eaten daily over a period of nine days. A definite increase in laxation rate resulted. It was not possible for W. E. A. to continue further on this experiment and determine the effect of washed bran. However, these observations emphasized the importance of repeating the experiments described under part 2 but using a basal diet more constipating in its effects. These additional studies are described in part 3.

Part 3.—*A Comparative Study of the Laxative Effects of Whole Bran and Washed Bran in Healthy Men Exhibiting a Marked Degree of Constipation.*—Experimental Details: The observations here reported were made on four healthy men. The general plan of experimentation was the same as that followed in the experiments described in part 2. Two of the individuals (W. E. A. and M. L. P.) had served as subjects for the previous experiments. Subsistence on the new rations resulted in marked constipation in their cases. Of the two remaining persons, one showed pronounced intestinal stasis; the other (R. L. R.) defecated once a day but felt distinctly uncomfortable while exhibiting this laxation rate and considered himself a good subject for the experiment. It is an interesting fact that R. L. R.'s rate of once a day, like that of the persons on the experiments described in part 2, was also associated with a daily fiber intake of approximately 50 mg. per kilogram of body weight. This relationship and its significance is discussed in a later section of this paper.

Subjective Impressions as a Criterion of Laxation: The subjective impressions recorded during the periods of subsistence on the basal diet alone were unanimous in emphasizing the difficulty of bowel movement and, frequently, the feeling that evacuation was incomplete. In contrast to this are the records for the bran periods indicating that defecations now were easy to perform, satisfying in character, and accompanied by the impression that all dejecta had been eliminated. No difference could be noticed in the effect obtained with whole bran as contrasted with that for the washed product.

Amount of Intestinal Contents Evacuated: As was the case in the previous experiments described in parts 1 and 2, ingestion of either whole or washed bran resulted in daily evacuation of an increased amount of material. The data presented in table 4 show not only the average weight of dejecta eliminated by each individual per day but also the average amount evacuated at each defecation. Comparison of these averages with those obtained in the experiments with a "borderline" or "mildly constipating" diet (part 2) is not without interest. In order to facilitate such a comparison, these average data from table 3 are included in table 4.

The average amounts of dejecta per day yielded by the persons when on the more constipating basal diet of the present experiments (periods 1 and 3, table 4) are lower than those for the corresponding basal periods of the study described in part 2, in which a "mildly constipating" basal ration was used. We are inclined to believe that the differences, although not large, are significant; but we hesitate to stress this point. When the more constipating diet was used, the amounts eliminated per defecation regardless of diet and period showed a rather remarkable agreement suggesting that the urge to defecate is dependent to an appreciable extent on the presence in the lower bowel of what might perhaps be spoken of as a "threshold mass."

The data given in table 4 confirm the conclusion indicated by the other criteria of laxation discussed, that there is no difference in the laxative values of whole and of washed bran.

### Laxation Rate as a Criterion of Laxative Action

Table 5 presents the data concerning the number of times the individuals defecated in the various periods. As not all of the periods were of seven days' duration comparison is facilitated by calculation of the rates of laxation—the number of movements per day; these data are also incorporated in table 5.

The constipating effect of the basal ration used in this study is made manifest if one compares the rates of laxation prevailing in the basal periods 1 and 3 of table 5 with those for similar periods in table 2, in which the rates yielded by the basal diet were approximately once a day. Many of the rates shown in table 5 were less than one, indicating that the persons concerned frequently passed a day without having a bowel movement.

Table 5.—*The Number and Rate of Defecations Observed When the Basal Diet was Markedly Constipating in Its Effects*

| Person | Number in Seven Day Periods* | | | | Rate per Day in Periods* | | | |
|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |
| W. E. A. | 5 | 8 | 6 | 8 | 0.7 | 1.1 | 0.9 | 1.1 |
| M. L. P. | 6 | 12 | 10† | 13 | 0.9 | 1.7 | 1.0 | 2.0 |
| R. L. R. | 7 | 16 | 6 | 14 | 1.0 | 2.4 | 1.0 | 2.1 |
| R. H. W. | 5 | 9 | 8† | 10 | 0.7 | 1.3 | 0.8 | 1.6 |

* Periods 1 and 3, basal diet only; period 2, basal diet plus whole bran; period 4, basal diet plus washed bran.

† Ten day period instead of seven days because of hang-over effect of the previous period.

In contrast to the results obtained in the studies described in parts 1 and 2, the objective data presented in table 5 abundantly confirm the subjective impressions indicating that both whole bran and washed bran possess demonstrable laxative power when tested under these conditions. Comparison of periods 2 and 4—"whole bran" periods, respectively—with the basal periods 1 and 3 brings out this fact clearly and supports the conclusion that there is no appreciable difference in the laxative values of washed bran and the natural product. This is a confirmation of the conclusion reached by consideration of the subjective impressions recorded. Evidently, then, the use of a more constipating diet for this study has been justified. The entire investigation described thus far strongly suggests that the technic often employed by students of laxation, namely, mere administration of the test product to individuals subsisting on various uncontrolled diets, and recording of a positive or negative effect on laxation, is an inadequate means of approach to the problem. A substance evidently may exhibit considerable laxative power when tested on a definitely constipated individual but yield a negative response when administered to a person whose condition in this respect is "borderline" or "normal."

TABLE 6.—*Summary of Average Intervals Between Defecations Observed When the Basal Diet was Markedly Constipating in Its Effects*

| Person | Period 1 Basal Diet Only, Hours | Period 2 Basal Diet Plus Whole Bran, Hours | Period 3 Basal Diet Only, Hours | Period 4 Basal Diet Plus Washed Bran, Hours |
|---|---|---|---|---|
| W. E. A. | 39 | 14 | 28 | 24 |
| M. L. P. | 29 | 14 | 25 | 12 |
| R. L. R. | 27 | 12 | 21 | 12 |
| R. H. W. | 36 | 20 | 30 | 17 |
| Average | 34 | 15 | 26 | 16 |

*Time of Passage of Material Through the Alimentary Tract as a Criterion of Laxation:* The duration of the interval between defecations will stand in inverse relation to the state of laxation occurring. The interval might be as short as that characteristic of a severe diarrhea; on the other hand it might be as long as twelve months, as in the famous case of constipation described by Geib and Jones.[11] In table 6 are presented the data concerning the duration of the interval between defecations obtained in the present experiments. They indicate, as do the subjective impressions and the objective data pertaining to rates of laxation and amount of material eliminated, that there is no difference in the laxative power of whole bran and washed bran, when these products are fed in fiber-equivalent amounts to constipated individuals.

It will be noticed in table 6 that the average interval in basal period 3 was shorter than that for period 1. The individuals on the experiment all gained the impression that in period 3 there was a hang-over effect from period 2.

*Water Content of the Stool as a Criterion of Laxation:* The reasons for believing that the water content of the stool may serve as an index of laxation have already been presented and need not be repeated here. In discussing the data obtained from this study bearing on this question it is pertinent to repeat that the influence of water intake on laxation was minimized as far as possible in the present study. Each person drank a constant, selected and suitable volume of water daily.

The percentage of water present in the stools of the persons in these experiments was on the whole quite constant. Data obtained from each series of feeding trials are presented in table 7. In studying these figures it should be borne in mind that they are the result of determinations for moisture content of the total combined stools for the period. When the data in table 7 were studied, and the tendency toward formation of a stool of constant water content was recognized, there was considered the possibility that the water content of the stool varies appreciably from day to day, and that data of the sort presented in table 7, being averages, really obscure such daily differences. This possibility received support from the observation that certain stools, selected as representative of a constipated condition because of difficulty in passing, seemed on gross inspection to be drier than other specimens and actually proved on analysis to have an appreciably lower content of moisture. It seemed worth while, therefore, to study the water content of a large number of individual freshly passed dejecta. An opportunity for doing this was presented when another series of feeding trials was carried out in which two bran products were tested for laxative potency on eight normal men who subsisted on basal diets that were markedly constipating in their effects, being essentially of the type used in the experiments of part 3. Each person submitted for moisture determination specimens which proved to be difficult to pass and which were interpreted as evidence of definite constipation. The results of these determinations are given in table 8.

It will be noticed in table 8 that there were several specimens in which the moisture content was quite definitely below the averages given in table 7. The grand average in table 8 is 66 per cent, as compared with 72 per cent in table 7. The specimens regarded as representative of marked constipation, therefore, were in fact slightly more dehydrated. The differences, however, are small and their significance questionable. The conclusion that seems to be justified by these observations is that the water content of the stools is of little value as a criterion of laxation.

TABLE 7.—*Water Content of the Stool as a Criterion of Laxation*

[11] Geib, Daniel; and Jones, J. D.: Unprecedented Case of Constipation, J. A. M. A. 38: 1304 (May 17) 1902.

W. E. A. experimented further in an endeavor, first, to determine how best to alter the basal ration so as to produce a more constipated condition in himself and, secondly, to test the effect of ingestion of bran on the condition thus produced. The basal diet used previously (part 1) is shown in table 1. As a result of the elimination of potatoes from this ration and the reduction of the daily intake of bananas from 350 Gm. to 200 Gm., marked intestinal stasis developed. When this had prevailed for eight days, 30 Gm. of whole bran was eaten daily over a period of nine days. A definite increase in laxation rate resulted. It was not possible for W. E. A. to continue further on this experiment and determine the effect of washed bran. However, these observations emphasized the importance of repeating the experiments described under part 2 but using a basal diet more constipating in its effects. These additional studies are described in part 3.

Part 3.—*A Comparative Study of the Laxative Effects of Whole Bran and Washed Bran in Healthy Men Exhibiting a Marked Degree of Constipation.*—Experimental Details: The observations here reported were made on four healthy men. The general plan of experimentation was the same as that followed in the experiments described in part 2. Two of the individuals (W. E. A. and M. L. P.) had served as subjects for the previous experiments. Subsistence on the new rations resulted in marked constipation in their cases. Of the two remaining persons, one showed pronounced intestinal stasis; the other (R. L. R.) defecated once a day but felt distinctly uncomfortable while exhibiting this laxation rate and considered himself a good subject for the experiment. It is an interesting fact that R. L. R.'s rate of once a day, like that of the persons on the experiments described in part 2, was also associated with a daily fiber intake of approximately 50 mg. per kilogram of body weight. This relationship and its significance is discussed in a later section of this paper.

Subjective Impressions as a Criterion of Laxation: The subjective impressions recorded during the periods of subsistence on the basal diet alone were unanimous in emphasizing the difficulty of bowel movement and, frequently, the feeling that evacuation was incomplete. In contrast to this are the records for the bran periods indicating that defecations now were easy to perform, satisfying in character, and accompanied by the impression that all dejecta had been eliminated. No difference could be noticed in the effect obtained with whole bran as contrasted with that for the washed product.

Amount of Intestinal Contents Evacuated: As was the case in the previous experiments described in parts 1 and 2, ingestion of either whole or washed bran resulted in daily evacuation of an increased amount of material. The data presented in table 4 show not only the average weight of dejecta eliminated by each individual per day but also the average amount evacuated at each defecation. Comparison of these averages with those obtained in the experiments with a "borderline" or "mildly constipating" diet (part 2) is not without interest. In order to facilitate such a comparison, these average data from table 3 are included in table 4.

The average amounts of dejecta per day yielded by the persons when on the more constipating basal diet of the present experiments (periods 1 and 3, table 4) are lower than those for the corresponding basal periods of the study described in part 2, in which a "mildly constipating" basal ration was used. We are inclined to believe that the differences, although not large, are significant; but we hesitate to stress this point. When the more constipating diet was used, the amounts eliminated per defecation regardless of diet and period showed a rather remarkable agreement suggesting that the urge to defecate is dependent to an appreciable extent on the presence in the lower bowel of what might perhaps be spoken of as a "threshold mass."

The data given in table 4 confirm the conclusion indicated by the other criteria of laxation discussed, that there is no difference in the laxative values of whole and of washed bran.

Laxation Rate as a Criterion of Laxative Action: Table 5 presents the data concerning the number of times the individuals defecated in the various periods. As not all of the periods were of seven days' duration, comparison is facilitated by calculation of the rates of laxation—the number of movements per day; these data are also incorporated in table 5.

The constipating effect of the basal ration used in this study is made manifest if one compares the rates of laxation prevailing in the basal periods 1 and 3 of table 5 with those for similar periods in table 2, in which the rates yielded by the basal diet were approximately once a day. Many of the rates shown in table 5 were less than one, indicating that the persons concerned frequently passed a day without having a bowel movement.

Table 5.—*The Number and Rate of Defecations Observed When the Basal Diet was Markedly Constipating in Its Effects*

| Person | Number in Seven Day Periods* | | | | Rate per Day in Periods* | | | |
|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |

| M. L. P. | 6 | 12 | 10† | 13 | 0.9 | 1.7 | 1.0 | 2.0 |
| R. L. R. | 7 | 16 | 6 | 14 | 1.0 | 2.4 | 1.0 | 2.1 |
| R. H. W. | 5 | 9 | 8† | 10 | 0.7 | 1.3 | 0.8 | 1.6 |

* Periods 1 and 3, basal diet only; period 2, basal diet plus whole bran; period 4, basal diet plus washed bran.

† Ten day period instead of seven days because of hang-over effect of the previous period.

In contrast to the results obtained in the studies described in parts 1 and 2, the objective data presented in table 5 abundantly confirm the subjective impressions indicating that both whole bran and washed bran possess demonstrable laxative power when tested under these conditions. Comparison of periods 2 and 4—"whole bran" periods, respectively—with the basal periods 1 and 3 brings out this fact clearly and supports the conclusion that there is no appreciable difference in the laxative values of washed bran and the natural product. This is a confirmation of the conclusion reached by consideration of the subjective impressions recorded. Evidently, then, the use of a more constipating diet for this study has been justified. The entire investigation described thus far strongly suggests that the technic often employed by students of laxation, namely, mere administration of the test product to individuals subsisting on various uncontrolled diets, and recording of a positive or negative effect on laxation, is an inadequate means of approach to the problem. A substance evidently may exhibit considerable laxative power when tested on a definitely constipated individual but yield a negative response when administered to a person whose condition in this respect is "borderline" or "normal."

TABLE 6.—*Summary of Average Intervals Between Defecations Observed When the Basal Diet was Markedly Constipating in Its Effects*

| R. H. W. | 36 | 20 | 30 | 17 |
| Average | 34 | 15 | 26 | 16 |

Time of Passage of Material Through the Alimentary Tract as a Criterion of Laxation: The duration of the interval between defecations will stand in inverse relation to the state of laxation occurring. The interval might be as short as that characteristic of a severe diarrhea; on the other hand it might be as long as twelve months, as in the famous case of constipation described by Geib and Jones.[11] In table 6 are presented the data concerning the duration of the interval between defecations obtained in the present experiments. They indicate, as do the subjective impressions and the objective data pertaining to rates of laxation and amount of material eliminated, that there is no difference in the laxative power of whole bran and washed bran, when these products are fed in fiber-equivalent amounts to constipated individuals.

It will be noticed in table 6 that the average interval in basal period 3 was shorter than that for period 1. The individuals on the experiment all gained the impression that in period 3 there was a hang-over effect from period 2.

Water Content of the Stool as a Criterion of Laxation: The reasons for believing that the water content of the stool may serve as an index of laxation have already been presented and need not be repeated here. In discussing the data obtained from this study bearing on this question it is pertinent to repeat that the influence of water intake on laxation was minimized as far as possible in the present study. Each person drank a constant, selected and suitable volume of water daily.

The percentage of water present in the stools of the persons in these experiments was on the whole quite constant. Data obtained from each series of feeding trials are presented in table 7. In studying these figures it should be borne in mind that they are the result of determinations for moisture content of the total combined stools for the period. When the data in table 7 were studied, and the tendency toward formation of a stool of constant water content was recognized, there was considered the possibility that the water content of the stool varies appreciably from day to day, and that data of the sort presented in table 7, being averages, really obscure such daily differences. This possibility received support from the observation that certain stools, selected as representative of a constipated condition because of difficulty in passing, seemed on gross inspection to be drier than other specimens and actually proved on analysis to have an appreciably lower content of moisture. It seemed worth while, therefore, to study the water content of a large number of individual freshly passed dejecta. An opportunity for doing this was presented when another series of feeding trials was carried out in which two bran products were tested for laxative potency on eight normal men who subsisted on basal diets that were markedly constipating in their effects, being essentially of the type used in the experiments of part 3. Each person submitted for moisture determination specimens which proved to be difficult to pass and which were interpreted as evidence of definite constipation. The results of these determinations are given in table 8.

It will be noticed in table 8 that there were several specimens in which the moisture content was quite definitely below the averages given in table 7. The grand average in table 8 is 66 per cent, as compared with 72 per cent in table 7. The specimens regarded as representative of marked constipation, therefore, were in fact slightly more dehydrated. The differences, however, are small and their significance questionable. The conclusion that seems to be justified by these observations is that the water content of the stools is of little value as a criterion of laxation.

[11] Geib, Daniel; and Jones, J. D.: Unprecedented Case of Constipation, J. A. M. A. 38:1304 (May 17) 1902.

significantly higher one, the change in laxation is evident almost immediately. The question of habit with respect to laxation must also be considered; it is difficult to evaluate this factor. In the present study there was one definite instance of the positive effect on laxation of the mental state of the person.

The observations made in the present study indicate that the rate of laxation, although not the most sensitive criterion of laxative effects, nevertheless is the most valuable. The following reasons are suggested: The capacity of the large intestine for holding fecal material is quite considerable. By reference to tables 3 and 4 it becomes evident that the average weight of each stool may be increased by approximately 25 per cent. If the increased fiber intake is small and only sufficient to bring about an increase in the weight of the stool of about this order of magnitude, evidently this extra amount of ingested fiber will not bring about any increase in the rate of laxation. If the additional amount of material to be eliminated is so great that it cannot be taken care of by this normal capacity for increase in weight of the stool, more stools must be formed and passed; this will reveal itself in an increase in laxation rate.

The observations made in these investigations suggest that the various criteria used in measuring laxative effects, when ranked according to their sensitivity in revealing improvement in laxative conditions, would be listed as follows: (1) subjective impressions; (2) appreciable increases in the amount of intestinal contents eliminated each day; (3) average time of passage of material through the alimentary tract, and (4) rate of laxation, or number of movements per day. Criteria 3 and 4 have about the same degree of sensitivity. With this list in mind it becomes evident that, whenever the new conditions are sufficiently effective to bring about a definite change in the rate of laxation or in the time of passage of material through the alimentary tract, the effect on laxation may be regarded as having been demonstrated in very objective fashion.

food residues play in promoting elimination, but this recognition seems to have been only with respect to the qualitative aspect. The present investigation contributes information on the quantitative side. Numerous data for fiber content of foods are at hand in reference books available to students of nutrition, but quantitative data on the physiologic side have not been available. Without in any way minimizing the importance of other factors influencing laxation, or the presence in numerous foods of other indigestible materials besides fiber—pentosans, for example—it seems reasonable to attempt some application of the observations of this research in human physiology.

Following out this idea, calculations have been made to determine the amounts of various representative foods that are required as sources of fiber to supplement a "very constipating" and a "borderline" diet for an average healthy man weighing 70 Kg. in order to reach the physiologic fiber minimum previously suggested. Conceivably, somewhat larger amounts may be required to attain a physiologic fiber optimum. The calculations are presented in table 12 and have been

Table 12.—*Sources of Fiber to Supplement a Very Constipating and a Borderline Diet* *

| | | For Use With | | | |
|---|---|---|---|---|---|
| | | Very Constipating Ration (As Used in Part 3, for Example) | | Borderline Ration (As Used in Part 2, for Example) | |
| Food | Fiber Content, per Cent | Gm. | Ounces | Gm. | Ounces |
| Bran, washed | 14.9 | 25.5 | 0.8 | 15.4 | 0.5 |
| Bran, whole | 10.4 | 36.5 | 1.2 | 22.1 | 0.75 |
| Grapes | 4.3 | 88 | 3.0 | 53 | 1.75 |
| Peaches | 3.6 | 106 (2)† | 3.5 | 64 | 2.1 |
| Pears | 2.7 | 141 (2) | 4.3 | 85 | 2.8 |
| Apples | 1.2 | 316 (4) | 10.5 | 191 | 6.3 |
| Banana | 1.0 | 380 (5) | 12.6 | 230 | 7.6 |
| Cabbage | 1.1 | 345 | 11.5 | 220 | 7.0 |
| Spinach | 0.9 | 421 | 14.0 | 255 | 8.1 |
| Lettuce | 0.7 | 543 | 18.1 | 328 | 11.0 |
| Peanuts | 2.5 | 156 | 5.0 | 96 | 3.2 |
| Almonds | 2.0 | 190 | 6.3 | 115 | 3.8 |
| Whole wheat bread | 1.2 | 316 | 10.5 | 191 | 6.3 |
| Graham bread | 1.1 | 345 | 11.5 | 220 | 7.0 |
| Rye bread | 0.5 | 760 | 25.3 | 460 | 15.3 |

* These calculations are based on the following data and assumptions: very constipating diet contains 2.5 Gm. of fiber per day; borderline diet has 4 Gm. of fiber per day. A man weighing 70 Kg. is to receive a daily total of 6.3 Gm., or 90 mg. of fiber per kilogram daily. The amounts in columns 3 and 5 yield 3.8 and 2.3 Gm. of fiber, respectively.

† Numbers in parentheses indicate approximate number of peaches, pears, and the like, yielding this amount. In the case of the banana and similar foods, the raw starch present probably exerts a definite influence on laxation; likewise, organic acids in the case of other fruits, berries and similar foods.

Fiber Content of the Diet in Relation to Laxation: The importance of giving attention to the amount of indigestible material present in the diet, when studying the problem of laxation, is well known. Fiber, or cellulose, is perhaps the most common of the indigestible substances present in the foods of man and therefore assumes considerable importance in a study such as is described in this paper. For this reason the comparison of whole bran with the washed product was made on a fiber-equivalent basis. As these test products were found to have the same laxative potency, it may be concluded that the laxative action of bran is due predominantly to the fiber present and not to phytin or other bran constituents that are readily extracted by treatment with weak acid. This confirms the work of Williams,[5] carried out on dogs, and of Falcon-Lesses,[12] performed on rats. Therefore the statement often made in the literature that the laxative action of bran is due chiefly to the phytin which it contains is erroneous.

Alimentary Disappearance of Fiber: In the investigation here reported, several interesting observations were made bearing on the rôle of fiber or indigestible material in laxation. In stating that the laxative value of an edible substance is due primarily to the fiber it contains, one must guard against creating the impression that the so-called fiber is totally indigestible and remains entirely intact in its passage through the alimentary tract of man. If the amounts of fiber ingested and subsequently excreted by way of the stools are known, it becomes possible to determine whether the fiber that is eaten has passed through the alimentary canal unchanged, and also to what extent any increase in bulk of the intestinal excreta is due to the additional fiber ingested. Earlier studies of this nature (reviewed by Schmidt and Strasburger [13]), have shown that there is a variable utilization of the cellulose contained in different vegetables. For example, in some experiments the fiber from cabbage almost completely disappeared in contrast to about 47 per cent of the fiber of lentils.[14] The data obtained in the present investigation and presented in table 9 likewise indicate that appreciable amounts of ingested fiber disappear in the course of alimentary passage through man.

Calculations were also made to determine the extent to which the fiber of the whole bran and the washed bran disappeared following ingestion. This was done by comparing the increments of food and fecal fiber in (*a*) the whole bran period 2 over basal period 1, (*b*) the whole bran period 2 over the basal period 3, and (*c*) the washed bran period 4 over the basal period 3. Such calculations can be only approximate. From the results of the calculations presented in table 10 it is evident that more of the fiber contained in both the whole and the washed bran passes through the alimentary tract unchanged than is the case with the fiber contained in the foods comprising the basal diet. This is a confirmation of work reported in the literature. Reference has already been made to the observations of Lohrisch, showing that a relatively large amount of the fiber of cabbage disappears during alimentary passage as compared with the fiber of lentils. Other work bearing more directly on the question of the utilization of bran is that of Rubner,[15] who made a study in men of the extent to which the cereal brans disappear when fed in the form of coarse black bread. Examination of his data [16] reveals that about 56 per cent of the bran disappeared. This figure is considerably greater than the averages presented in our table 10. Perhaps the difference is related to the fact that in Rubner's experiments almost 2 ounces of bran was ingested daily, whereas in the present study the daily intake was from 1 to 1½ ounces. Differences in the milling processes by which the brans were prepared also might account in part for these observed differences.

Modification of the Demonstrable Laxative Value of Bran by the Amount of Fiber Already Present in the Diet: The tests of whole and of washed bran on individuals exhibiting marked constipation resulted in the demonstration that these substances possess definite laxative power. In the earlier studies described, the amount of fiber already present in the basal diet, on which the bran product was superimposed, was great enough to bring about a laxation rate of at least once a day, and the addition to this of the amount contained in an ounce of bran was not sufficient to improve laxation except as measured by subjective sensations and the amount of material evacuated. The ratio of bran or other test-substance fiber to the total fiber in the diet seems to be of importance, therefore, if the laxative power of the test product is to be demonstrated beyond question. In table 11 are given, for purposes of comparison, the values of this ratio for the preliminary feeding trials, those with a "borderline" or "mildly constipating" diet (part 2), and those obtained when the individuals were markedly constipated (part 3). From table 11 it appears that, in order to demonstrate clearly in normal men the laxative power of bran (or other test source of fiber), the ratio of fiber in the test material to the total fiber in the diet must

approximate the value 0.6. It would be interesting to perform similar experiments with nonfiber sources of roughage in order to determine whether this finding applies to indigestible residues in general.

The Relation Between Ingested Fiber and the Rate of Laxation: The observations presented in table 11 suggested that a detailed examination of the data for ingested fiber in relation to the rate of laxation might yield significant and interesting results. Fifty-six instances were available for study in which the fiber intake per kilogram of body weight per day and the number of bowel movements per day were known. W. E. A. served as the subject in every series of feeding trials. Therefore, in his particular case it was possible to plot five separate points for laxation rates, ranging from 0.8 to 1.2 movements per day and corresponding fiber intakes from 38 to 112 mg. per kilogram per day. These data, when plotted on coordinate paper, suggested a logarithmic relationship between these two variables; another plot on arith-log paper gave the surprising relationship presented in the accompanying chart. Line *AB* represents the best straight line plot for all the data that run through the intersection of the axes; *CD* is the line running through all but one of the plotted points.

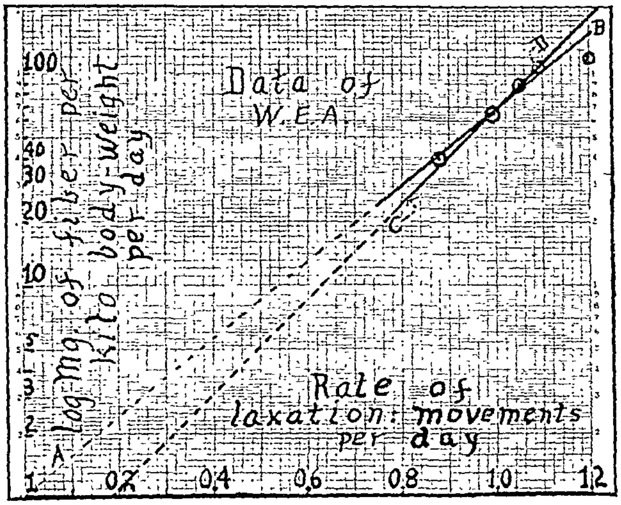
TABLE 11.—*Relation of the Demonstrable Laxative Power of Bran to the Total Amount of Fiber in the Diet*

| Prevailing Condition of Laxation on the Basal Diet | Movements per Day When on the Basal Diet Average | Ratio of Test Substance Fiber to Total Fiber Ingested | Is a Laxative Potency Demonstrated? |
|---|---|---|---|
| Part 1: preliminary study; "two movements per day" | 2.05 | 0.34 | No |
| Part 2: mild constipation; "once a day" | 1.00 | 0.44 | Subjective criteria: yes; objective criteria: ? |
| Part 3: marked constipation; "less than once a day" | 0.88 | 0.59 | Yes |

As a conservative interpretation of the chart, it might be stated that the range of values for the logarithm of fiber intake is not great, running from 1.58 (log of 38) to 2.08 (log of 112), and that, therefore, the relationship may be of a first approximation order only, and not of very great significance. On the other hand, it is of interest to point out that a projection of line *CD* cuts the *x* axis at a value of about 0.2; in other words, if this relationship is significant within the range of values covered by plot *CD* and holds for extrapolated points representing lower values of the respective variables, and the fiber intake per day is reduced to zero, a laxation rate of 0.2 per day, or once in five days, is obtained. Approximately this value was actually obtained in a separate study on dogs. These animals were fed an artificial diet supplemented by measured amounts of various sources of indigestible material. Subsistence on the basal diet devoid of roughage resulted in defecation about once every four days. In view of this observation we are inclined to believe that the relationship presented in the chart is more significant than the conservative interpretation just given would indicate. As further evidence in support of this view we may cite the finding that the fifty-six cases secured in this study, in which values for the fiber intake per kilogram per day and laxation rate were obtained, conformed to this relationship. All cases in which the daily fiber intake was less than 50 mg. per kilogram exhibited laxation rates with values of less than once a day; intakes of fiber ranging from 50 to 63 mg. per kilogram were associated with defecations once a day, interpreted subjectively as "mild constipation"; when the intakes of fiber were 70 mg. and over, laxation was regarded as satisfactory by subjective criteria in every instance, some persons, however, requiring a daily fiber intake of from 90 to 100 mg. per kilogram in order to secure excellent laxation, as judged by all criteria, both subjective and objective in nature.



Data of W. E. A.

Several observations of importance in relation to the interpretation of laxation data should be mentioned. When an individual has been subsisting at a relatively high level of fiber intake and changes suddenly to a significantly lower level, there is a considerable hang-over effect. A period of four or more days is necessary before the effect of the low fiber diet on laxation can be clearly shown. This finding throws doubt on the validity of the conclusions drawn in studies of laxation in normal human beings, in which the experimental periods have been as short as four days. It is possible, therefore, for a person to exhibit different rates of laxation with the same fiber intake, depending on whether the observation of laxation rate in the low-fiber period is begun immediately or an intervening period of adjustment to the new level is allowed. When one goes from a low-fiber level to a significantly higher one, the change in laxation is evident almost immediately. The question of habit with respect to laxation must also be considered; it is difficult to evaluate this factor. In the present study there was one definite instance of the positive effect on laxation of the mental state of the person.

The observations made in the present study indicate that the rate of laxation, although not the most sensitive criterion of laxative effects, nevertheless is the most valuable. The following reasons are suggested: The capacity of the large intestine for holding fecal material is quite considerable. By reference to tables 3 and 4 it becomes evident that the average weight of each stool may be increased by approximately 25 per cent. If the increased fiber intake is small and only sufficient to bring about an increase in the weight of the stool of about this order of magnitude, evidently this extra amount of ingested fiber will not bring about any increase in the rate of laxation. If the additional amount of material to be eliminated is so great that it cannot be taken care of by this normal capacity for increase in weight of the stool, more stools must be formed and passed; this will reveal itself in an increase in laxation rate.

The observations made in these investigations suggest that the various criteria used in measuring laxative effects, when ranked according to their sensitivity in revealing improvement in laxative conditions, would be listed as follows: (1) subjective impressions; (2) appreciable increases in the amount of intestinal contents eliminated each day; (3) average time of passage of material through the alimentary tract, and (4) rate of laxation, or number of movements per day. Criteria 3 and 4 have about the same degree of sensitivity. With this list in mind it becomes evident that, whenever the new conditions are sufficiently effective to bring about a definite change in the rate of laxation or in the time of passage of material through the alimentary tract, the effect on laxation may be regarded as having been demonstrated in very objective fashion.

Is there a physiologic roughage minimum? The data obtained in this investigation suggest strongly that there is such a thing as a minimum amount of roughage compatible with satisfactory laxation in healthy men. As a result of a review of all the data for fiber intake in relation to laxation rate, the following statements appear justified: A laxation rate of once a day, which, however, is not often accompanied by subjective impressions of satisfactory laxation, is obtained in healthy men with a daily fiber intake of from 50 to 60 mg. per kilogram of body weight. With some individuals an increase of this intake to from 70 to 80 mg. resulted in a satisfactory laxative condition. Other persons, notably those showing a greater tendency to constipation, required from 90 to 100 mg. per kilogram daily in order to insure good laxation. So far as we are aware, no data of this sort have been published before. These observations certainly suggest the existence of what might be called a physiologic roughage minimum, which, for normal men, might be expressed in terms of a daily fiber intake of from 90 to 100 mg. per kilogram of body weight.

In advancing this suggestion we do not wish to be understood as ignoring the influence on laxation of such factors as habit, emotional states, the presence in certain foods of substances having a stimulating action on intestinal motility, and other factors at present only vaguely recognized. The literature on laxation is full of recognition of the important part the indigestible food residues play in promoting elimination, but this recognition seems to have been only with respect to the qualitative aspect. The present investigation contributes information on the quantitative side. Numerous data for fiber content of foods are at hand in reference books available to students of nutrition, but quantitative data on the physiologic side have not been available. Without in any way minimizing the importance of other factors influencing laxation, or the presence in numerous foods of other indigestible materials besides fiber—pentosans, for example—it seems reasonable to attempt some application of the observations of this research in human physiology.

Following out this idea, calculations have been made to determine the amounts of various representative foods that are required as sources of fiber to supplement a "very constipating" and a "borderline" diet for an average healthy man weighing 70 Kg. in order to reach the physiologic fiber minimum previously suggested. Conceivably, somewhat larger amounts may be required to attain a physiologic fiber optimum. The calculations are presented in table 12 and have been applied to representatives of different types of food. Such a calculation can be extended readily to include many other foods.

Table 12.—*Sources of Fiber to Supplement a Very Constipating and a Borderline Diet* *

| | | For Use With | | | |
|---|---|---|---|---|---|
| | | Very Constipating Ration (As Used in Part 3, for Example) | | Borderline Ration (As Used in Part 2, for Example) | |
| Food | Fiber Content, per Cent | Gm. | Ounces | Gm. | Ounces |
| Bran, washed | 14.9 | 25.5 | 0.8 | 15.4 | 0.5 |
| Bran, whole | 10.4 | 36.5 | 1.2 | 22.1 | 0.75 |
| Grapes | 4.3 | 88 | 3.0 | 53 | 1.75 |
| Peaches | 3.6 | 106 (2)† | 3.5 | 64 | 2.1 |
| Pears | 2.7 | 141 (2) | 4.3 | 85 | 2.8 |
| Apples | 1.2 | 316 (4) | 10.5 | 191 | 6.3 |
| Banana | 1.0 | 380 (5) | 12.6 | 230 | 7.6 |
| Cabbage | 1.1 | 345 | 11.5 | 220 | 7.0 |
| Spinach | 0.9 | 421 | 14.0 | 255 | 8.1 |
| Lettuce | 0.7 | 543 | 18.1 | 328 | 11.0 |
| Peanuts | 2.5 | 156 | 5.0 | 96 | 3.2 |
| Almonds | 2.0 | 190 | 6.3 | 115 | 3.8 |
| Whole wheat bread | 1.2 | 316 | 10.5 | 191 | 6.3 |
| Graham bread | 1.1 | 345 | 11.5 | 220 | 7.0 |
| Rye bread | 0.5 | 760 | 25.3 | 460 | 15.3 |

* These calculations are based on the following data and assumptions: very constipating diet contains 2.5 Gm. of fiber per day; borderline diet has 4 Gm. of fiber per day. A man weighing 70 Kg. is to receive a daily total of 6.3 Gm., or 90 mg. of fiber per kilogram daily. The amounts in columns 3 and 5 yield 3.8 and 2.3 Gm. of fiber, respectively.

† Numbers in parentheses indicate approximate number of peaches, pears, and the like, yielding this amount. In the case of the banana and similar foods, the raw starch present probably exerts a definite influence on laxation; likewise, organic acids in the case of other fruits, berries and similar foods.

Inspection of table 12 shows clearly that whole and washed bran, because of their relatively great fiber content, have high supplementing value in laxation. Of the fruits listed, grapes, peaches and pears prove to be of greatest value. The vegetables cabbage, spinach and lettuce are next. Peanuts and almonds, although richer in crude fiber than these vegetables, probably cannot contribute a very large amount of fiber to the diet because of their content of oil and consequently high caloric value. The common breads given in the table have about the same content of fiber as the apple, the banana and the leafy vegetables, and therefore should be of about equal value as sources of roughage; when these cereal products are eaten in only moderate quantities, they contribute only small amounts of fiber; when eaten in large amounts as staple foods, their yield of fiber would be comparable to that of the fruits and vegetables cited. This indicates that these breads can serve as valuable sources of food fiber. It is recognized that these estimations are only approximate, but it is believed that they can serve as aids in the wise selection of foods with the view to securing intake of the "physiologic fiber optimum."

### COMMENT

Reference has already been made to the widely discussed criticisms by Alvarez of the use of bran in the diet. The results of this research give indications of the potency of bran as a laxative in the case of healthy men. The evidence pointing to the existence of a physiologic roughage minimum—or shall we say optimum—is worthy of serious consideration and seems to afford a basis on which to rest an explanation of the controversy that has arisen concerning the value of bran as a laxative. It is quite likely that many cases of constipation are due simply to failure to ingest sufficient roughages, either through ignorance or through an unwarranted assumption that a high-roughage diet is being ingested; these individuals may really be subsisting on a diet the roughage content of which is below the physiologic minimum and therefore should obtain relief by raising the level of roughage intake to the optimum. The data secured in this research are believed to be of value in answering the question as to what level of roughage intake constitutes the physiologic optimum. Another group of cases exhibiting constipation and much more likely to come to the attention of the clinician is made up of individuals presenting other symptoms, such as pain, along with the constipation. Cases of spastic colitis and similar conditions, in which an irritable colon is an important feature of the syndrome, belong in this class. It is quite possible that the form of the roughage is of special importance for these persons; the colonic wall may be unduly sensitive to discrete particles in such cases. Finally there should be mentioned the cases of constipation observed in the clinic that are due to obstructive conditions, such as a misplaced uterus, or neoplasms, for example. It is obvious that raising the level of fiber intake to the physiologic minimum may be a totally inadequate therapeutic measure in such cases. With these considerations in mind, therefore, it should be clear that sweeping generalizations may be quite unwarranted.

### SUMMARY AND CONCLUSIONS

The laxative value of whole wheat bran was studied in three series of experiments on eleven healthy men subsisting on carefully controlled diets. This was compared with the value for laxation of a bran that had been treated with weak acid in order to remove the phytin. Measured by the several criteria used in this study, there was no difference in the laxative values of these two products. It was concluded that the laxative value of bran is due predominantly to the fiber present, regardless of phytin or other bran constituents that are readily extractable by treatment with weak acid. The statement often made in the literature that "the laxative value of bran is due largely to the phytin which it contains" is erroneous. In making bran products for human consumption the indications of this research are that the laxative value of such materials may be estimated fairly accurately from the fiber content.

The data obtained in this research support the view that in healthy men a definite relationship exists between the rate of laxation and the amount of fiber ingested daily per unit of body weight. This points to the existence of a physiologic roughage minimum, which, in terms of fiber, is obtained with an intake of from 90 to 100 mg. of fiber per kilogram of body weight daily. Such an intake of fiber by healthy men should contribute definitely toward securing satisfactory laxation. A somewhat greater fiber intake may be required to secure the physiologic fiber optimum. In an attempt to indicate practical applications of these observations, calculations of additional fiber in terms of common foods, required by a healthy man weighing 70 Kg. to supplement borderline and markedly constipating diets, have been made.

# DIFFERENTIAL DIAGNOSIS BETWEEN TYPHUS AND SPOTTED FEVER

## REPORT OF A CASE AND THE ISOLATION OF A NEW MILD TYPE OF SPOTTED FEVER VIRUS

HOBART A. REIMANN, M.D.
HENRY L. ULRICH, M.D.
AND
LUTHER C. FISHER, M.D.
MINNEAPOLIS

The occasion for differential diagnosis between typhus fever and Rocky Mountain spotted fever has recently assumed importance. Although it is stated in current textbooks[1] that the likelihood of encountering both typhus and spotted fever in the same locality is extremely unlikely, newer studies have revealed that spotted fever is not localized in the Northwest but that a distinct variety is widespread east of the Appalachian Mountains.[2] Cases have also been reported in Texas.[3] Typhus fever, on the other hand, has been observed not only in the East and Southeast but also in California, in Minnesota[4] and as far north as Montreal.[5] The diagnosis of the latter two cases, however, was not proved. The Minnesota case was diagnosed on clinical grounds alone in 1915 before refinements for laboratory diagnosis had been developed. The case observed in Montreal was diagnosed from clinical and pathologic data, but no confirmatory immunity tests were made. It is important, therefore, considering the widespread distribution of both diseases, that the true nature of infection should be determined in every sporadic case of either disease.

Clinically, there are many points of resemblance between spotted fever and typhus fever, especially Old World typhus, as pointed out by Ricketts and Wilder.[6] Endemic typhus, formerly called Brill's disease, is a relatively mild infection. Differentiation may be made to some extent in regard to the season during which the disease occurs; epidemic (Old World) typhus is most prevalent in winter; endemic typhus in summer and fall; and spotted fever in spring and summer. The

overlapping of incidence unfortunately is great enough to render differentiation on this basis uncertain. If a history of previous insect bite is available it is important to know that epidemic typhus is transmitted by lice, endemic typhus by rat-fleas, and spotted fever by ticks. The specific histologic changes in the blood vessels of the skin in typhus fever serve to distinguish it from other acute infectious diseases, but the lesions are similar to those found in spotted fever and are of no value in differentiation. The only certain method of differentiation requires immunologic procedures which are based on the observations of Ricketts and Wilder,[6] who showed that animals immune to typhus fever are not immune to spotted fever, and vice versa.

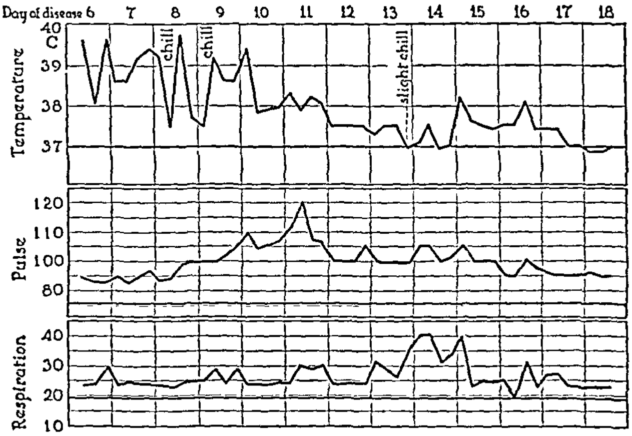

Fig. 1.—Temperature, pulse and respiration record of a patient with spotted fever. The relatively slow pulse appeared early in the course. The high respiratory rate accompanied bronchopneumonia.

An example of the methods employed in establishing an etiologic diagnosis is described in a case report by Otto.[7] A technician, accidentally infected in a laboratory, contracted a fatal illness thought at first to be typhus fever. The infecting virus obtained from the patient's blood was inoculated into guinea-pigs for propagation by passage from animal to animal. By subsequent immunity tests, the virus proved to be that of spotted fever.

The following case is presented because of twofold interest: (1) a presentation of the methods employed in establishing an etiologic diagnosis, and (2) the identification of a new mild type of spotted fever.

### REPORT OF CASE

A Jew, aged 67, was proprietor of a rooming house for transients in a densely populated portion of the city. There was nothing pertinent in his family history or past history; his health was usually good.

While at a nearby summer resort, he was bitten twice by wood ticks. About ten or twelve days later (May 18, 1931) he noted malaise. On the following day there was high fever, dizziness and photophobia. He drove his automobile home to the city and narrowly escaped several accidents en route. On the same day he was obliged to go to bed by the severity of his symptoms. He complained of partial deafness. The first chills occurred May 21. About this time (third day of illness) a rash was noted on his arms. He entered a hospital on the sixth day of his illness, under the care of Dr. T. T. Warham.

The patient appeared to be very ill; muttering stupor was present, but when aroused he cooperated satisfactorily. The lips and ears were cyanotic, the throat was reddened, and there were punctate injected areas over the uvula and soft palate. There was slight conjunctivitis. The pupils were equal and reacted normally. The lungs were clear. A systolic murmur was audible. The blood pressure was 120 systolic and 50 diastolic. The liver and spleen were not palpable nor were any abnormal lymph nodes evident. The reflexes were undisturbed. The eruption involved most of the body surface except the head and the neck and was particularly striking in the palms and soles. The rash was maculopapular, discrete and confluent, and of a dusky pink. The color faded partially on pressure. The laboratory tests showed 7,000 leukocytes, a trace of albumin and hyaline casts in the urine, and a negative Widal test. A blood culture taken at this time was sterile. Typhoid was considered as a possible diagnosis.

Two days later on the eighth day of the illness the rash became hemorrhagic and no longer faded on pressure. At this time one of us (H. L. U.) was called in consultation. Because of the developing rigidity of the patient's neck, meningitis was suspected, but the spinal fluid proved to be normal. Typhus fever was then considered. On the ninth day, a roentgen examination revealed a density in the left lung, but clinical evidence of pneumonia was delayed for three days. Bronchitis had been present for several days but the cough became much worse. The patient became delirious and appeared to be moribund. He was incontinent, restless, and at times excited. At this time one of us (H. A. R.), who had previous experience with Old World typhus, saw the patient and on clinical grounds alone agreed with the impression of typhus fever.

The Weil-Felix reaction at this time was positive in a low dilution, 1:80, and doubtfully positive at 1:160 (National Institute of Health). Oxalated blood was injected intraperitoneally into guinea-pigs on this, the twelfth day of illness. A leukocytosis of 12,000 accompanied the pneumonia.

After this time there was gradual improvement, and on the thirteenth day the temperature reached the normal level but rose again for several days before convalescence began, as shown in figure 1. The rash by this time had faded to a dirty brownish color. The patient left the hospital on the twenty-ninth day after the onset of illness and was still confused mentally. The titer of the Weil-Felix reaction on the twenty-fourth day was 1:1,280.

It is of interest to note that the cases of Otto[7] and Kemp,[3] the cases reported along the Atlantic seaboard,[2] and our own were first considered to be typhus fever but proved later by immunologic methods to be spotted fever. As a result of previous experience with typhus fever we were led to consider typhus fever first in our own case, although the infection took place early in May. The fact that the patient owned a rooming house and accommodated transients suggested the possibility of the importation of some typhus vector by a guest coming from an endemic center. It was not until later when the patient became rational and when Dr. Perkins of the Minnesota State Board of Health made an investigation that a history of tick bites was obtained. Tick bites are very common in Minnesota and have never been regarded seriously heretofore. Nevertheless, Rocky Mountain spotted fever was then considered. Certain clinical features, such as the presence of conjunctivitis, the deafness, the development of pneumonia, and the absence of splenic tumor, resembled the behavior of Old World typhus. The gradual onset and defervescence, the early appearance of the rash on the arms on the third day, and the disturbances

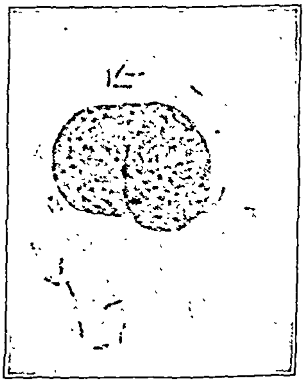

Fig. 2.—Rickettsia of Minnesota type of spotted fever located in a cell obtained from the scrotal exudate of a guinea-pig. Giemsa stain.

7. Otto, R.: Centralbl. f. Bakt., Orig. **106**: 279, 1928.

of the central nervous system favored spotted fever as a diagnosis. The Weil-Felix reaction is of no value in differentiation, since it occurs in both diseases.

It is clear, then, that although certain clinical and epidemiologic differences exist between spotted fever and typhus fever, positive diagnosis can be made only by laboratory methods involving animal experimentation.

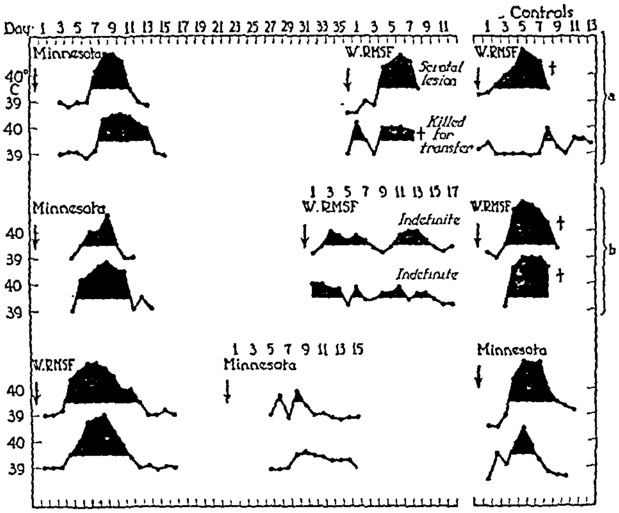

Fig. 3.—Cross-immunity tests with the Bitter Root (Western) strain of spotted fever: Daily temperature records of (a) guinea-pigs convalescent from Minnesota strain and not immune (!) to spotted fever (Dyer and Rumreich); (b) two animals convalescent from Minnesota strain which are immune to spotted fever (experiment by Parker); two animals convalescent from spotted fever which are immune to Minnesota strain. Control animals reacted positively for each group, except one animal in a. The arrows indicate the time of inoculation.

## BIOLOGIC DIFFERENTIATION

Two guinea-pigs were inoculated intraperitoneally with 2 cc. of oxalated blood obtained from the patient on the twelfth day of his illness. One guinea-pig failed to react, but the second developed fever seventeen days later, which lasted three days. Blood was obtained by heart puncture on the second day and inoculated into two fresh animals. Fever appeared on the sixth and eighth days, respectively. The strain, for convenience called "Minnesota" strain, was thus established in guinea-pigs. Transfers to fresh animals were then made by removing the brain aseptically on the second or third day of fever, emulsifying it in physiologic solution of sodium chloride and injecting it intraperitoneally into fresh animals. With small doses of from one-tenth to one-twentieth brain, fever often failed to develop. When one-fourth brain was injected the reaction was more constant. Of 68 animals thus inoculated, fever developed on the fifth day in 3, sixth day in 10, seventh day in 21, eighth day in 16, ninth day in 3, and from the tenth to the twelfth day in 5. Fever failed to appear in ten inoculated guinea-pigs. Fever lasted one day in 3, two days in 11, three days in 7, four days in 7, five days in 7, six days in 8, and seven days in 1. It was then found that the transfer of blood was more convenient and gave more constant results. Thereafter, more than 90 animals were inoculated with 3 cc. of blood obtained by heart puncture from lightly anesthetized guinea-pigs on the second and third days of fever. By this method, fever usually developed earlier, on the fifth or sixth day, and lasted on the average two or three days longer. Typical fever curves are illustrated in figures 3, 4 and 5. None of the inoculated animals died. Scrotal edema and redness, with adherence of the testes to the tunica sac, occurred in about 50 per cent of the males. Several animals were killed during the fever and examined. No gross pathologic changes were observed aside from an enlarged spleen, scrotal swelling and inflammation.

Histologically, the scrotal exudate contained polymorphonuclear leukocytes, macrophages and mesothelial cells. Certain mesothelial cells contained from 20 to 40 rickettsia per cell (fig. 2). The rickettsia were bacillary and often appeared to be diploform. They were somewhat larger and fewer to a cell than the rickettsia observed in the scrotal exudate in endemic typhus. Far fewer cells contained rickettsia of the Minnesota strain than in endemic typhus. Pinkerton,[8] using tissue culture methods, succeeded in maintaining viable rickettsia for several weeks in the frozen state.

In one animal there was a marked diffuse perivascular infiltration of lymphocytes around the arterioles of the vas deferens. The vessel walls were normal. There was mononuclear cell infiltration around certain arterioles of the tunica. Here and there was slight evidence of endothelial proliferation. The tunica was involved in a nonspecific inflammation and covered with exudate. No important changes were found in the brain.

A male rabbit inoculated with blood virus developed a low fever after five days, which lasted for three days. The scrotum was red and slightly swollen.

The characteristics exhibited by the Minnesota strain in guinea-pigs differ in several respects from the behavior of other varieties of rickettsial diseases. The Western Bitter Root type (fig. 3) and Eastern type spotted fever (fig. 4) have a shorter incubation period, cause a more violent fever reaction, and often cause death of the animals. The Bitter Root strain causes superficial necrosis of the scrotum, ears and snout. Scrotal involvement, on the other hand, rarely occurs with Eastern type spotted fever, and exudate covering the tunica and containing rickettsia has not been found.

There are greater similarities between the behavior of the Minnesota strain and typhus fever. Guinea-pigs rarely die from Old World typhus. Scrotal reaction occasionally occurs and rickettsia are found in the exudate.[9] Brain lesions, however, are frequent and characteristic in typhus fever but do not occur with the Minnesota strain.

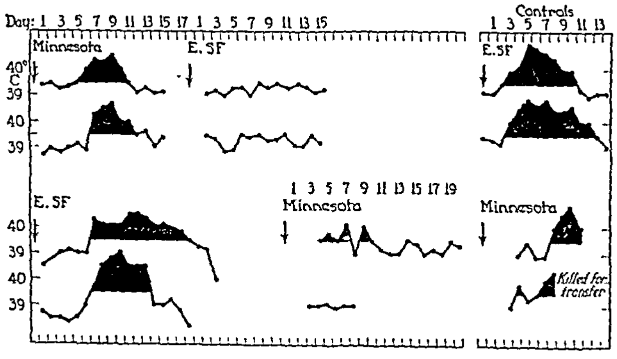

Fig. 4.—Immunity tests with Eastern spotted fever. Guinea-pigs immune to Minnesota strain do not react to Eastern spotted fever virus, and vice versa. All controls reacted positively.

In endemic typhus in guinea-pigs, the incubation period is longer, the fever curve is more irregular (fig. 5), the scrotal swelling is more constant, and the exudate is more copious and contains many more rickettsia[10] than in infections due to the Minnesota strain. It appears, therefore, that the Minnesota strain has certain features in common with both spotted fever and typhus and is either a variety of one or the other, or an intermediate type. The similarities and differences in the reactions of various rickettsial diseases in guinea-pigs are shown in the accompanying table.

[9] Pinkerton, Henry: J. Infect. Dis. 44: 337 (May) 1929.

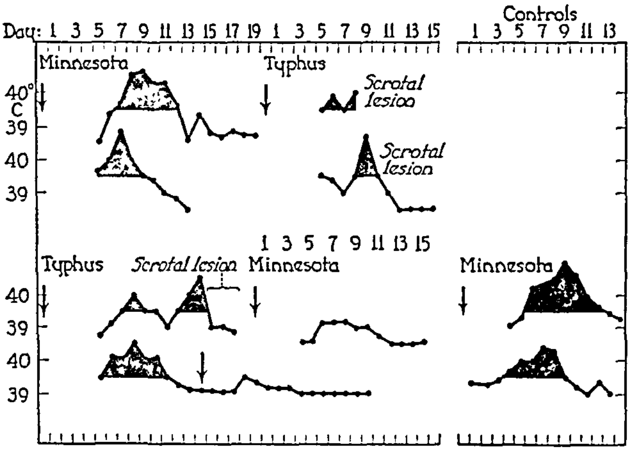

Fig. 5.—Immunity tests with endemic typhus virus. Two guinea-pigs convalescent from Minnesota strain are not immune to typhus virus; two animals immune to typhus are immune (!) to Minnesota strain. Controls are positive.

## IMMUNITY EXPERIMENTS

*Cross-Immunity Tests with the Bitter Root Strain of Spotted Fever.*—Six guinea-pigs immune to spotted fever as a result of convalescence from infection with the Bitter Root strain were sent to us through the courtesy of Dr. R. R. Parker from the U. S. Public Health Service Laboratory at Hamilton, Mont. These animals, together with five fresh guinea-pigs, were inoculated with the Minnesota strain. None of the guinea-pigs convalescent from spotted fever manifested signs of infection, while the fresh animals did. A few of the temperature charts are illustrated in figure 3.

*Comparative Observations in Varieties of Experimental Rickettsial Disease in Guinea-Pigs*

| | Incubation in Days | Duration in Days | Mortality per Cent | Scrotal Reaction in Males | Exudate on Spleen | Brain Lesions |
|---|---|---|---|---|---|---|
| Bitter Root spotted fever... | 2-5 | Usually fatal | 80+ | Superficial necrosis | ? | Frequent |
| Eastern spotted fever............ | 2-6 | 5-10 | 25 | Rare | ...... | Many small focal glioses |
| Old World typhus | 5-10 | 5-10 | 0 | Rare, few rickettsia when exudate occurs | Often | Constant numerous |
| Endemic typhus.. | 2-19 | 2-10 | 0 | Constant with copious exudate; many rickettsia | Occasionally | Frequent in females; in males only after subcutaneous inoculation |
| Minnesota strain. | 5-12 | 1-7 | 0 | 50% with exudate, few rickettsia | Rare | Rare |

Conversely, three animals immune to the Minnesota strain were sent to Dr. Parker for inoculation with Bitter Root spotted fever. Two showed a low-grade type of fever (indefinite reaction) while one remained unaffected.[8] Three control animals developed typical spotted fever, two of which are illustrated in figure 3 *b*.

Four animals immune to the Minnesota strain were also sent to Drs. Rumreich and Dyer, at the National Institute of Health in Washington, D. C., where similar tests were made. Curiously, when these animals were inoculated with the Western type of spotted fever, two of the Minnesota immunes developed fever (fig. 3 *a*) with scrotal lesions typical of Western spotted fever. The remaining two showed atypical low fever.[8]

*Immunity Tests with Eastern Spotted Fever.*—A strain of this type of virus was sent to us from the National Institute of Health for tests in our laboratory. Guinea-pigs immune to the Minnesota strain as a result of convalescence therefrom proved to be immune to the virus of Eastern spotted fever. Conversely, animals recovered from Eastern spotted fever were immune to the Minnesota strain. The results are shown in figure 4. Similar results were obtained by Dr. Pinkerton at Harvard University, to whom the Minnesota strain was sent.[8]

*Effect of Spotted Fever Vaccine.*—Several guinea-pigs received two intraperitoneal injections of spotted fever vaccine (supplied by the Montana laboratory) at five-day intervals. Three weeks after the first injection they were inoculated with the Minnesota strain, together with three controls. The vaccinated animals were protected from infection, while the controls developed typical fever, and two developed scrotal swelling.

*Immunity Tests with Endemic Typhus Virus.*—A strain of typhus virus (Wilmington) was supplied to us by Dr. Pinkerton and established in our laboratory. Immunity tests showed that guinea-pigs convalescent from infection with the Minnesota strain were not immune to typhus virus. Pinkerton obtained similar results. Surprisingly, five animals recovered from typhus fever in our hands proved to be immune to Minnesota virus, while four fresh ones developed typical reactions (fig. 5). Pinkerton's results differed in regard to the latter result. In his experiments, typhus failed to protect against the Minnesota strain; in fact, typhus immunes were used to propagate the Minnesota strain.[8]

## COMMENT

The clinical report of a case is presented which was at first believed to be typhus fever but proved to be spotted fever after immunity experiments had been made. Emphasis is laid on the necessity of biologic procedures in determining an etiologic diagnosis. Differentiation on the grounds of clinical, epidemiologic or pathologic data is uncertain.

Studies of the reaction of the virus after its establishment in guinea-pigs indicated a number of features which distinguish it from other strains of rickettsial disease thus far reported. The low virulence for guinea-pigs, the scrotal swelling, and the presence of rickettsia in the scrotal exudate resembles the reaction of typhus more than that of spotted fever. On the other hand, the results of the immunity tests point to a closer relationship with spotted fever. The conflicting results of several tests, namely, the failure in two instances of the Minnesota strain to confer immunity against Western spotted fever, as found by Dyer, and the apparent protection conferred by typhus fever against the Minnesota strain in our experience, are puzzling. These results suggested that the Minnesota strain might be of an intermediate variety.

We feel, however, that another explanation is likely. The Minnesota strain produces a comparatively mild disease in guinea-pigs and may thereby evoke weak immunity, too weak to protect regularly against a strain of such high virulence as the Bitter Root variety of spotted fever. On the other hand, endemic typhus may conceivably confer a certain grade of nonspecific immunity which, in our hands at least, was sufficient to protect guinea-pigs against the weakly virulent Minnesota strain. But from the results of other tests, namely, the reciprocal immunity conferred by the Minnesota strain and Eastern spotted fever, and by the protection conferred against infection with the Minnesota strain by spotted fever vaccine, it appeared that the Minnesota strain represents an exceptionally mild type of spotted fever.

# TUBERCLE BACILLI IN THE STOMACH CONTENT OF CHILDREN WITH POSITIVE TUBERCULIN TEST

## PRELIMINARY REPORT

CAMILLE KERESZTURI, M.D.
LUCY MISHULOW, B.A.
BÉLA SCHICK, M.D.
AND
DOROTHY BEHNER, M.A.
NEW YORK

The demonstration of tubercle bacilli in the stomach content of children is important because:

1. It may help to make the diagnosis of tuberculosis in certain cases presenting negative physical and roentgen signs and showing a positive tuberculin test as the only indication of tuberculosis.
2. It may help in estimating the activity of the tuberculous process.
3. It makes it possible to separate the children who are passing tubercle bacilli, and therefore are dangerous to their surroundings, from those who are healed or well arrested and do not spread tubercle bacilli and therefore are harmless to their environment.

To wash out the stomach and search for tubercle bacilli in the sediment of the stomach content is a cumbersome method both for the patient and for the physician. Inoculation of guinea-pigs with the sediment of the stomach lavage is an essential part of the method but makes it expensive. Therefore, these procedures should be used only in those cases in which one cannot avoid them; i. e., in children under 4 or 5 years of age who cannot be taught to expectorate.

This study was made on forty children in the Sea View Hospital.

### TECHNIC

The stomach lavage was carried out in the morning on an empty stomach, from 200 to 300 cc. of physiologic solution of sodium chloride being used. Only one lavage was done in each case.

The specimens were centrifugated for one hour at high speed. The sediment was suspended in about 3 to 5 cc. of sterile water and treated with an equal amount of 3 per cent sodium hydroxide. This was incubated at 37 C. for thirty minutes and made neutral to phenolphthalein with 15 per cent hydrochloric acid.

In the early part of this investigation, cultures of some of the treated sediment were grown on Corper's and Löwenstein's mediums and the remainder was inoculated into guinea-pigs subcutaneously. But most of our specimens were contaminated with molds, and the cultures were so badly overgrown that we discontinued making cultures and inoculated the entire sediment into guinea-pigs. The contamination was probably due to the fact that at least twenty-four hours passed between the stomach lavage and the bacteriologic study, which, for technical reasons, could not be avoided.

Smears were made of the sediment of each specimen and examined for acid-fast bacilli, but all of them were negative.

If any of the guinea-pigs died and showed suspicious lesions but no acid-fast bacilli, the suspicious tissue was subinoculated into other guinea-pigs.

In all guinea-pigs in which the lesions were grossly tuberculous, a smear examination was made, and the result was recorded as positive only when acid-fast bacilli were found. Altogether, we used 173 guinea-pigs in this experiment. The number of animals used seems to have but little to do with the frequency of positive results. In the group that gave positive results, we used an average of two pigs per child. In the cases that gave negative results, we inoculated an average of four guinea-pigs per case.

In one case, tests on both guinea-pigs were negative, but there was one colony on Löwenstein's medium which proved to be fully virulent for guinea-pigs.

### SELECTION OF CASES

All cases had a positive tuberculin test. Most of them had a Pirquet test first, and if this happened to be negative a Mantoux test of 0.1, 0.2, 2, 5 or 10 mg. of old tuberculin was done.

All the patients were afebrile or nearly so, having a temperature of less than 100 F. by mouth or by rectum. The flat temperature curve was occasionally interrupted by a febrile acute nontuberculous condition lasting a few days.

All these children gained weight, the speed of gain being different in the individual cases. It was not difficult to select afebrile children and children who gained in our tuberculosis institution because by proper limitation of activity, i. e., more bed rest, we were able to make most of our patients gain and become afebrile. The children who were continuously losing weight and had fever in spite of forced rest and open air treatment in our institution were in most instances seriously ill, presented far advanced cases, had abundant positive sputum, positive throat swab or positive feces examination, and were not included in this study.

### AGE

The ages of the children under examination varied from 2 years to 10⅓ years. The average age of the seven children who gave positive stomach lavage was 4.4 years, whereas the average age of those who were negative was 5.9 years. This finding might be interpreted in two ways:

1. The younger the child, the more likely it is that he swallows his sputum instead of spitting it up.
2. The younger the child, the more likely it is that we are dealing with a fresh and active tuberculous process, the sign of which is the presence of bacilli in the expectoration or in the stomach content.

---

From the Sea View Hospital and the City of New York Department of Health.

The bacteriologic work was done in the Bureau of Laboratories of the City of New York Department of Health, under the general supervision of Dr. William H. Park, by Miss Lucy Mishulow and Miss Dorothy Behner. The lavage itself was carried out by Dr. Radwin, one of the resident physicians of Sea View Hospital. We purposely did but one single stomach lavage on this group of forty children. We are convinced that, by repetition of the procedure, the frequency of positive results would increase. However, we were mainly interested in the results that one single lavage gave us.

### SPEED IN GAINING WEIGHT

Our entire group gained weight at an average of 0.6 pound (272 Gm.) a month. The average gain for the positive lavage group was 0.55 pounds (250 Gm.) and of the negative, 0.64 pound (290 Gm.) a month. But as the average gain in a group of children 4.4 years of age is supposed to be greater than in a group of children 5.9 years of age, it is obvious that the relative speed of gain of children who gave positive results was definitely smaller than the relative rate of gain in the group who gave negative stomach lavage. This somewhat slower average gain in weight in the positive stomach lavage group also speaks for our supposition that the presence of the bacilli in the stomach content points toward fresh or active tuberculosis. On the other hand, some authors, like Holt, think that 4 year old and 6 year old children gain with equal speed. If so, the slight difference between the two groups would be insignificant.

### EXAMINATION OF FECES FOR TUBERCLE BACILLI

One would think that tubercle bacilli in the stomach content passing through the intestine could easily be recovered from the feces. During the hospitalization of our forty children, twenty-five had from one to five examinations of the feces. One of the children who had positive stomach lavage and fourteen who had negative ones had no feces examination. All the stools of the others examined were negative for tubercle bacilli. The explanation of these negative observations was that probably the few bacilli passing the stomach were so diluted in a big mass of feces that it was hard to find them unless one used practically the total amount of feces for examination. In our hospital 50 Gm. of stool was used for the search for acid-fast bacilli.

The other fact that has to be considered in evaluating the discrepancy between the results of our stomach lavage and the feces examination is that the two examinations were not made at the same time; the feces examination was an admission routine, whereas stomach lavage was done as a special piece of work a few months later. On the other hand, if the two methods were equally sensitive, one would expect more positive observations on admission than later on, because these forty children were all improving during their hospital stay.

The feces and sputum examinations were made in the pathologic laboratory of Sea View Hospital under the supervision of Dr. Cornelius Mezei.

### EXAMINATION OF SPUTUM

The sputum of thirty-five children in this group of forty was examined with three positive results. These three positive ones were in the group that was negative with stomach lavage. But this is not necessarily a contradictory finding, because the sputum examinations and the lavage were not done at the same time. The positive sputum occurred one year and one and one-half years before and, in the third case, two months after the stomach lavage was done. Of the five children whose sputum was not examined, four were in the negative and one was in the positive gastric lavage group.

### COUGH

Cough is not as frequent among tuberculous children as it is in tuberculous adults. None of the patients who had a positive lavage, coughed, and only seven, i.e., 21 per cent of those who had a negative lavage, coughed noticeably. Four of these patients also had bronchiectasis, and three, some form of pleurisy. The severity of the tuberculosis and the cough did not seem to parallel each other.

### ONSET OF TUBERCULOSIS

Our information as to the onset of tuberculosis is inaccurate because we had to take the word of the family and also because the onset in some cases was insidious. In many of the cases there were never any symptoms. The child was sent to Sea View Hospital on the basis of a positive tuberculin test done in some health station or clinic as a routine. Judging as best we could, we estimated that the average duration of tuberculosis up to the present date in our negative stomach lavage group was twenty-nine months and in our positive stomach lavage group, twenty-one months. This bears out again the same point that we mentioned before; i. e., the fresher the tuberculous lesion, the more likely one is to find positive sputum or positive stomach lavage.

### TUBERCULIN TESTS

In all the cases but four, a Pirquet test preceded the Mantoux test. All the Pirquet tests were positive except three in the negative lavage group, but even these three cases gave a positive Mantoux test.

We tried to determine some relationship between the size of the reaction of the Mantoux test and the activity and intensity of the process. Although it is hard to evaluate our Mantoux tests because different doses of old tuberculin were used, there seems to be no relationship between the size of the test and the degree and activity of tuberculosis.

### PHYSICAL EXAMINATION

It is well known that the childhood type of tuberculosis frequently gives very meager clinical chest signs for percussion and auscultation. In our positive lavage group, we were not able to obtain pathologic physical signs in five out of seven cases, i. e., in 71 per cent; and in the negative stomach lavage group, twenty-one out of thirty-three cases, i. e., 64 per cent, were negative by percussion and ausculation. We expected to find negative chest signs less frequently in the cases that gave positive stomach lavage as compared with the negative group. It is interesting that among the patients who had tubercle bacilli in their stomachs, 71 per cent did not give positive physical signs at all, except on roentgen examination.

### CLASSIFICATION OF CASES FROM POINT OF VIEW OF TUBERCULOSIS

From the accompanying table one sees that pleurisy alone or combined with different forms of tuberculosis predominated in the group of children who gave positive stomach lavage results. By this we mean that out of seven patients five presented some sort of pleurisy; i. e., 71 per cent. On the other hand, in the negative lavage group, only seventeen out of thirty-three cases, i. e., 51 per cent, were combined with pleurisy. Of course, pleurisy in the different cases was in various stages of resorption, and even an interlobar line in the roentgenogram was considered as pleurisy.

The different forms of tuberculosis in our study are shown in the table.

### PROGNOSIS

We tried to evaluate all our cases from the point of view of prognosis, considering the type of tuberculous symptoms, age and general condition of the child. To those children who, according to our judgment, had the best chance for recovery, we gave a prognosis score of

100 per cent. To those children who, according to our opinion, will surely die of tuberculosis, we gave the score of 0 per cent. Patients who had an intermediate survival chance obtained a score between the extremes of 0 per cent and 100 per cent. Before knowing the result of the stomach lavage we gave a survival chance to our patients. The average survival grade on the patients who gave a positive lavage was 74 per cent, whereas on those giving negative results for tubercle bacilli by the stomach lavage the same score averaged 80 per cent. This again bears out the same point which was suggested in three previous instances, that a positive stomach lavage occurs more often in the presence of active tuberculous lesions and among young children. All these three factors, early age, fresh tuberculous process and active tuberculous process, make the prognosis worse. During the ten or twelve months that have elapsed since we started this study, twenty-five of the thirty-three, i. e. 75 per cent, of the children who gave negative gastric lavage left the hospital apparently cured, whereas only four of seven, i. e., 57 per cent, of the positive stomach lavage patients were ready for discharge. The eleven who are still in the hospital are presenting the same course as described in this article; i. e., they are gaining weight and are afebrile. By throat swabs none of them showed the presence of tubercle bacilli.

*Forms of Tuberculosis*

| Form of Tuberculosis | Positive Lavage | Negative Lavage |
|---|---|---|
| Osteomyelitis and hilus gland tuberculosis | 0 | 1 |
| Spondylitis | 1 | 0 |
| Latent tuberculosis | 0 | 5 |
| Hilus gland tuberculosis | 0 | 2 |
| Pleurisy with effusion | 1 | 3 |
| Interlobar pleurisy | 0 | 1 |
| Mediastinal pleurisy(?) | 0 | 1 |
| Pleurisy with effusion and central infiltration | 1 | 1 |
| Interlobar pleurisy and central infiltration | 1 | 2 |
| Interlobar pleurisy and parahilar infiltration | 1 | 1 |
| Interlobar pleurisy, central infiltration, scrofulosis | 0 | 1 |
| Pleurisy with effusion; interlobar pleurisy | 0 | 1 |
| Pleurisy with effusion and parahilar infiltration phlyctenular conjunctivitis | 0 | 1 |
| Mediastinal pleurisy(?) and bronchiectasis | 0 | 1 |
| Interlobar pleurisy and epituberculosis | 0 | 1 |
| Interlobar pleurisy, hilus gland tuberculosis phlyctenular conjunctivitis | 0 | 1 |
| Mediastinal(?) pleurisy, perihilar infiltration, phlyctenular conjunctivitis | 1 | 0 |
| Pleural adhesions and hilus gland tuberculosis | 0 | 1 |
| Empyema and latent tuberculosis | 0 | 1 |
| Hilus gland tuberculosis and bronchiectasis | 0 | 2 |
| Central infiltration and bronchogenic dissemination of tuberculosis | 0 | 1 |
| Central infiltration | 1 | 1 |
| Perihilar infiltration | 0 | 3 |
| Basal infiltration and tuberculosis verrucosa cutis | 0 | 1 |

### COMMENTS

The presence of tubercle bacilli in the stomach can be explained in three ways:

1. By far the most frequent cause is a tuberculous lung process which has connection with the air passages, and the bacilli are carried up to the pharynx either by the ciliary movement of the respiratory epithelium or by cough. From the pharynx the bacilli are swallowed.

2. Far less frequently there is a tuberculous lesion in the middle ear, in a sinus or in the nasopharyngeal cavity.

3. A third possibility is that the tubercle bacilli in the stomach were carried there by contaminated food. The probability of this is very small.

4. There is very rarely a secondary tuberculous lesion in the stomach itself. A primary lesion has never been described. This is usually developed as a part of a generalized tuberculosis.

In our study of the forty improving tuberculous patients who were all gaining weight and were all afebrile, the stomach lavage gave positive results in seven, i. e., 17.5 per cent. None of them had positive feces examination and only three of them (i. e., 7.5 per cent) gave positive sputum results at any time. Therefore, we think that stomach lavage is a useful method for the search of tubercle bacilli among children under 4 and 5 years of age who cannot be taught to expectorate.

### LITERATURE

The first author who suggested the use of stomach lavage for finding tubercle bacilli was Meunier in 1898. Armand-Delille, in 1927, published the next extensive article on the subject. Since that time similar articles have appeared in increasing numbers.[1] It is hard to compare other people's work with our own, because their selection of cases and the bacteriologic technic used is different from each other's and from ours.

### CONCLUSION

We succeeded in demonstrating in seven out of forty tuberculous children (17.5 per cent) tubercle bacilli in the stomach content. The average age of our group was 5.9 years. All of them were afebrile and gained weight.

**Glaucoma.**—Glaucoma is not a disease peculiar to the eye. Hypertension in the semicircular canals occurs in certain labyrinth diseases. But one must generalize still further and consider glaucoma as a syndrome which is found also in intracranial hypertension. When I speak of intracranial hypertensions I mean especially those which are associated with tumors of the brain. These are secondary cerebral glaucomas comparable to those secondary glaucomas known in the eye. One meets also with intracranial hypertensions in the course of meningitis and encephalitis. These resemble the glaucomas secondary to choroiditis and iridocyclitis. Lastly, in the condition which is designated by the term serous meningitis, a meningitis in which the spinal fluid is chemically normal, the disease evolves in a manner which reminds one strongly of simple chronic glaucoma. Other analogies could be found, but it is unnecessary to carry my point further; these comparisons suffice to show that the eye is but a department of the complete human organism and that ophthalmologists must turn toward general pathology in order to solve the problems which they encounter.—Magitot, A.: The Aqueous Humor in Glaucoma, *Arch. Ophth.* **6:** 661 (Nov.) 1931.

## ACCIDENTAL DIVISION OF THE PANCREAS

Orville Harry Brown, M.D., and Loren C. Barlow, M.D.,†
Phoenix, Ariz.

A man, aged 44, was in an automobile accident, Dec. 25, 1930, in which the car turned over, pinning his trunk at the upper abdominal level between the car and the curbstone. No further details of the accident were obtainable.

The patient was admitted to the hospital about 4:40 p. m., shortly after the accident. He was in a stupor and was hiccuping. He lay in bed on the right side with the arms flexed, so that his hands were in front of his face, and with his knees drawn up. He was restless, slightly groaning. He answered questions dully and hesitatingly in a muffled voice difficult to understand. He complained of stomach pains. He admitted that he had been drinking and said that his car had turned over with him. Further information could not be elicited.

Examination of the scalp gave negative results. The face had two or three superficially abraded areas, each about 20 mm. in diameter. There was no bleeding nor other discharge from the ears, eyes or nose. He was vomiting a dark tarry mucous material. The nurse said that at first there was a definite alcoholic odor to the vomitus.

The left pupil was definitely larger than the right. Both were moderately contracted. There was no deviation of the eyes. On being requested, he protruded his tongue in the midline.

The facial muscles and lines appeared equal on the two sides. There was no neck rigidity. Tests of expression were impossible.

The neck and the chest showed no abnormality. The heart sounds were of fair quality without murmurs. The size of the heart was about normal. The blood pressure was 96 systolic and 70 diastolic. Once it registered definitely 110/70. An occasional impulse came through higher. The abdomen was flaccid throughout, and palpation of it did not cause any apparent pain. There were two or three slight abrasions on the abdominal wall, each about 25 mm. in diameter. The back was normal except that the buttocks were generally reddish and slightly abraded here and there. The legs seemed normal. The Babinski, Gordon, Oppenheim, Chaddock, patellar and achilles reflexes were all negative.

The diagnosis was alcoholism, concussion of the brain and blood in the stomach, probably having been swallowed from a cut tongue or a bleeding nose.

It was recommended that the patient be kept in bed and carefully watched. Frequent readings of the blood pressure were to be made and the patient examined for signs of internal injury, perhaps of the stomach or intestine. An ice bag was to be placed to the head; instructions were given to wash the stomach if the vomiting continued.

Notes were again taken at 9:30. At that time the pupils were nearly of equal size but were sluggish and a bit contracted. The face and eye movements seemed normal. The abdomen was markedly spastic, almost "boardlike" and tender, probably more on the right than on the left and probably more above the umbilicus than below. The evidence pointed to a ruptured viscus; a rupture of the duodenum or of a connected organ was thought of because of the tarry appearing vomitus. The rigid abdomen was of the type seen in ruptured gastric ulcer or acute pancreatitis.

The patient was taken to the operating room at 10:30 p. m. of the day of the accident and operated on under ether anesthesia. Through a high right rectus incision, a large amount of blood was found in the peritoneal cavity. There was no rupture of the intestine, liver or spleen. The gallbladder was large and full of bloody bile. The lesser peritoneal cavity was more filled with blood than was the greater cavity. The pancreas was found to have been torn crosswise into two about equal parts. The two parts of the pancreas were approximated and sutured together; the bleeding vessels were ligated. A drain was inserted into the lesser peritoneal cavity and the abdomen was closed.

The patient had a mildly stormy course for several days but made a good recovery with a pancreatic fistula. The dressings needed frequent changing, as they absorbed a large amount of the reddish yellow material, later becoming lighter in color. There was considerable skin irritation about the incision even though it was kept covered with petrolatum. The drain was removed gradually after the third day. The patient was discharged from the hospital twenty days after admission. The drainage continued in gradually lessened amounts.

The urine obtained shortly after admission to the hospital contained albumin and an occasional red blood cell. Otherwise it was normal. On the 26th and the morning of the 27th, four specimens of urine contained sugar. Thereafter it was normal. The blood sugar on several examinations was never found abnormal.

The leukocyte count of the blood on the 26th was 13,700, with 79 per cent polymorphonuclears and 21 per cent mononuclears.

About May 1, 1931, he entered the United States veterans' hospital at Whipple, Ariz. Dr. Gail D. Allee, medical officer in charge, reported, October 16, that practically the only treatment that he received while in the hospital was the keeping of the sinus open in order that free drainage might be established. This secretion was sent to the laboratory on several different occasions, but it was not possible to demonstrate the presence of pancreatic fluid.

May 6, the sinus had been injected and a roentgenogram was made which showed the sinus well outlined, with the appearance of being a small cavity about 3½ inches (9 cm.) long by 1½ inches (3.8 cm.) in width.

The patient was discharged, May 25. He was readmitted to this hospital a few days ago, and the sinus had entirely healed and showed no evidence of drainage at this time. However, he complained of epigastric disturbances at the present time, especially following a meal of certain foods.

In January, 1930, Elias L. Stern [1] gave a digest of the literature of traumatic injuries to the pancreas. Four cases were of divided pancreas.

Travers,[2] in 1827, recorded the case of a drunken woman who had a violent contact with the wheel of a coach and was thrown to the ground. She succumbed after several days, and at autopsy the liver was found ruptured and the pancreas torn completely across.

Wilks and Noxon [3] reported a case in which the pancreas was divided into two parts.

Stern further refers to a specimen in the St. Bartholomew Hospital Museum. A person had been crushed between two vans. Death ensued in three days and at autopsy the pancreas was found divided into two nearly equal parts.

Heineke [4] reports the fourth case, in which a man was caught in a fall of earth and sustained a division in the midline of the pancreas. He made a complete recovery. Presumably he was operated on.

Based on Stern's review of the literature, this is the fifth case of complete division of the pancreas through accident, and the second with recovery, to be recorded.

Dr. William K. Fast [5] reported the use of a method of healing pancreatic fistulas, suggested by Caryl Potter [6] for healing duodenal fistulas. This consists of a catheter held in the fistula and packed around with gauze soaked in a 10 per cent aqueous solution of Witte's peptone; through the catheter tenth normal hydrochloric acid is instilled into the fistula, at the rate of 20 minims (1.25 cc.) per hour. A high caloric diet was maintained. He reported that digestion of the wound promptly ceased within twenty-four hours. From the fourteenth to the twenty-first postoperative day the granulating wound was kept covered with beef extract paste. The fistula was entirely healed by thirty days after the operation.

We might have obtained early healing of the wound by the use of the Potter technic.

SUMMARY

A case of complete division of the pancreas from an accident without other serious injury is herewith placed on record. This is the fifth case of this type to be recorded and the second patient to recover.

15 East Monroe Street.

# Council on Physical Therapy

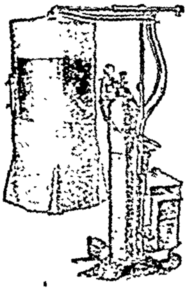
THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

H. A. CARTER, Secretary.

## HEIDBRINK MOTORLESS OXYGEN TENT, MODEL 40, ACCEPTABLE

The Heidbrink Oxygen Tent, Model 40, is manufactured by the Heidbrink Company, 2633 Fourth Avenue, Minneapolis. According to the firm, it is recommended for use as an adjunct in the administration of oxygen therapy where a supply of electric current is not available.

The Heidbrink Oxygen Tent, Model 40, consists essentially of a tent with a noninflammable window, an injector, a cabinet, a soda lime container and a supply of oxygen. The entire equipment is mounted on a triangular chassis, the wheels of which are equipped with roller bearings and are rubber tired. The shipping weight is about 230 pounds.



Heidbrink motorless oxygen tent, model 40.

The oxygen-air circulation is maintained by means of the energy of the oxygen under pressure forced through an injector which permits a flow of 6 cubic feet per minute in and through the tent; hence the confined oxygen-rich atmosphere is circulated and recirculated in the relatively closed gas system with the continuous addition of oxygen. A by-pass permits further addition of oxygen when needed.

The firm claims that the humidity is ordinarily maintained at less than 50 per cent and that a cooling at less than 15 degrees below room temperature may be reached.

The Heidbrink Company believes that the Heidbrink Oxygen Tent, Model 40, will provide suitable oxygen as a valuable aid in the early and permanent relief of anoxemia resulting from acute pulmonary edema, coronary thrombosis, cardiac decompensation, pneumonia, and carbon monoxide poisoning.

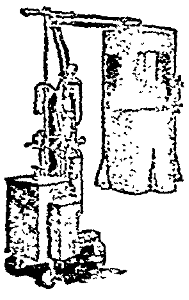
The Council on Physical Therapy declares the Heidbrink Motorless Oxygen Tent, Model 40, acceptable for inclusion in its list of accepted devices.

## HEIDBRINK OXYGEN TENT, MODEL 31, ACCEPTABLE

The Heidbrink Oxygen Tent, Model 31, manufactured by the Heidbrink Company, 2633 Fourth Avenue, Minneapolis, is recommended by the firm as a valuable "aid in the early and permanent relief of anoxemia resulting from acute pulmonary edema, coronary thrombosis, cardiac decompensation, pneumonia, and carbon monoxide poisoning."

The Heidbrink Oxygen Tent Model 31 consists essentially of a tent hood, a motor and blower, a soda lime container, a cooling chamber and an oxygen supply tank. The entire assembly is mounted on a chassis and is easily moved from place to place on roller bearing casters. The circulation of the oxygen-air mixture is maintained by a blower connected to a universal type motor totally enclosed to prevent open sparks from coming in contact with the air-oxygen mixture. The firm claims that the apparatus delivers oxygen to the patient, independently and under automatic regulation, in accurately measured quantities as desired, at from 1 to 15 liters per minute. Through an auxiliary valve, from 50 to 60 per cent and higher oxygen concentration may be built up in the tent within a few seconds; hence the oxygen-rich atmosphere is circulated and recirculated in the closed system with the continuous addition of oxygen to the atmosphere.

The motor blower unit is under rheostatic control; thus the volume of flow of oxygen-rich atmosphere through the closed circulating system may be controlled by the attending physician. Cooling of the oxygen-air mixture through the closed circulating system may be controlled by the attending physician. Cooling of the oxygen-air mixture is accomplished by passing the mixture over cracked ice. A temperature reduction of from 15 to 20 degrees F. below room temperature may be secured in the tent. It is claimed that the ice consumption is about 60 to 80 pounds for twenty-four hours. The firm claims that the oxygen-air mixture is deflected to avoid a strong draft directly hitting the patient.



Heidbrink oxygen tent, model 31.

Carbon dioxide is absorbed by soda lime packed in the blower return lead. A wire gauze basket (which holds about a twenty-four hour supply of soda lime) is conveniently located for removal and replacement of the soda lime from the circulation. A by-pass is provided in the circulating system to switch the soda lime in and out while the lime is being replenished. An attachment designed to administer carbon dioxide independently may be obtained, if desired, but is not recommended. The shipping weight is about 230 pounds.

The Council on Physical Therapy declares the Heidbrink Oxygen Tent, Model 31, acceptable for inclusion in its list of accepted devices.

## LASTEX SURGICAL STOCKINGS AND GARTER HOSE ACCEPTABLE

Lastex Surgical Stockings and Garter Hose are distributed and sold by Bauer & Black of Chicago.

The firm claims that the stockings and hose are knitted with Lastex yarn. This yarn has a rubber core thread made from Lastex rubber, around which is wound two layers of two-ply silk thread. The resulting yarn looks like silk and is knitted into fashion hosiery just as silk yarn is knitted.

The company claims that the fabric made of Lastex yarn stretches in all directions. The toe, heel and top of a Lastex stocking are made of nonelastic silk and lisle material far more serviceable than that ordinarily found in hosiery.

It is further claimed that the Lastex Stocking and Garter Hose are of light weight and relatively comfortable to the joints, and the pressure around the leg may be regulated by the height to which the garment is pulled. Lastex stockings may be worn without other hosiery, although the average woman will probably wear another stocking over it because of lack of color selection. Lastex is relatively inconspicuous when worn underneath regular hosiery. The firm claims that the Lastex Stocking is designed to be worn by women and the Lastex Garter Hose to be worn either by men or by women who do not need support above the knee. The Lastex stockings come in regular sizes 8½, 9, 9½, 10, 10½ and 11.

The Lastex Stockings and Garter Hose may be used as an adjunct in the treatment of varicose veins. This is the only therapeutic claim that the firm of Bauer & Black makes for the stockings and hose.

The Council on Physical Therapy declares the Lastex Surgical Stockings and Garter Hose acceptable for inclusion in its list of accepted devices.

---

**Indoctrination.**—Children throughout the world must learn caution in the face of physical danger, skill in handling themselves and their immediate environment, respect for property, formulae of politeness, and consideration for the comfort of others. The method of teaching varies with different cultures. Nowhere is the process of indoctrination perfectly smooth and untroubled. The degree of conflict and the type of difficulty aroused, however, seem to be correlated with the style of discipline current in the particular society to which the child belongs.—Levy, John: The Impact of Cultural Forms upon Children's Behavior, *Ment. Hyg.* **16:**209 (April) 1932.

# *Council on Pharmacy and Chemistry*

## NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

**IODOBISMITOL** (See The Journal, Feb. 13, 1932, p. 554).

The following dosage form has been accepted:

*Ampules Iodobismitol 2 cc.:* Each 2 cc. contains sodium iodobismuthite 0.12 Gm., sodium iodide 0.24 Gm., in ethylene glycol.

**METAPHEN** (See New and Nonofficial Remedies, 1931, p. 283).

The following dosage form has been accepted:

*Tincture Metaphen 1:200:* Metaphen 0.5 Gm., dissolved in a liquid composed of acetone 10 cc., water 40 cc., and alcohol 50 cc.

**SOLUTION LIVER EXTRACT NO. 343.**—A sterile aqueous solution of liver extract No. 343, preserved with 0.3 per cent of cresol. Each cubic centimeter contains the active material derived from 5 Gm. of liver.

*Actions and Uses.*—Solution liver extract No. 343 is proposed for intramuscular injection in the treatment of pernicious anemia.

*Dosage.*—Determined by the condition of the patient. Daily intramuscular injection of 2 cc. has been followed by maximal reticulocyte count. The maintenance dose varies with the individual patient.

Manufactured by Eli Lilly and Co., Indianapolis, Ind. No U. S. patent. U. S. trademark 243,147.

*Ampoules Solution Liver Extract No. 343, 10 cc.:* Each cubic centimeter contains the active material derived from 5 Gm. of liver.

To prepare solution liver extract No. 343, livers from edible animals are ground directly into water, and the mixture adjusted to the isoelectric point (approximately *p*H 5 to *p*H 6). The mixture is then heated to coagulate protein (approximately 80 C.), stirred for thirty minutes, and filtered. The filtrate is reduced in vacuum to a small volume and enough 95 per cent alcohol added to produce a concentration of 70 per cent. The precipitate that is formed is discarded and the filtrate reduced to a small volume; it is added to alcohol and the precipitate separated, dried in vacuum, dissolved in water; 0.3 per cent of cresol is added, and the mixture is filtered, sterilized and filled into ampules.

## REPORTS OF THE COUNCIL

The Council has authorized publication of the following reports.

W. A. Puckner, Secretary.

### CALLAWAY'S CREOSOTE, DE-MONO-HYDRATED, NOT ACCEPTABLE FOR N. N. R.

According to the label, "Callaway's Cresote, de-mono-hydrated," is "A 2½% aqueous solution of Beechwood Creosote U. S. P., from which the mono-hydric phenols (carbolic acid etc.) have been REMOVED, . . ." In the information sent to the Council by the Creo-Chemical Distributing Co. it is stated that "In the manufacture of this preparation a 2½% Beechwood Creosote U. S. P., is used in an aqueous solution, from which the mono-hydric phenols (carbolic acid etc.) have been removed" and that it "Contains all the elements of Creosote U. S. P., minus the mono-hydric phenols" and that it is colored red by a dye made from certified colors, but no definite statement of the composition was furnished. The firm submitted a report of an analysis made by a firm of analytic chemists which stated that a specimen marked Cre-Cal-Co received from the Creo-Chemical Distributing Company had been analyzed and that the material was found to have been made up of cresol, guaiacol, alcohol and glycerin and to have been free from other phenols. This analytic report bears a note from the Creo-Chemical Distributing Company to the effect that "Cre-Cal-Co" is now presented to the Council under the new name Callaway's Creosote, de-mono-hydrated. According to a Notice of Judgment issued by the Food and Drug Administration of the U. S. Department of Agriculture (The Journal, April 11, 1931, p. 1251) Cre-Cal-Co was found to consist essentially of small amounts of creosote, traces of salts of calcium, magnesium and sodium, phosphates, chlorides, and sulphates in water colored with a red dye. From these conflicting statements it is evident that a frank declaration of composition has not been made.

No information was furnished the Council in regard to the method by which the claimed elimination of phenol (carbolic acid, etc.) is accomplished, nor were tests furnished which could be used to demonstrate the absence of phenol. According to the label for Callaway's Creosote, de-mono-hydrated, the removal of the monohydric phenols (carbolic acid, etc.) from the creosote eliminates "all harmful ingredients, without impairing its medicinal properties, permitting therefore of unusually large dosage to obtain quick constitutional saturation." It is claimed that with this preparation "noticeably effective results in the treatment of lung infections" have been obtained in a remarkably short time. In the information sent the Council it is asserted that the preparation is "indicated in the treatment of a series of diseases, starting from a severe cold to pneumonia and influenza." It is stated that in "the treatment of tuberculosis and especially in a number of serious, third stage cases" there is "unquestioned evidence of definite improvement." It is also claimed that the product "has shown remarkable efficacy in the treatment of diphtheria, scarlet fever, venereal diseases and erysipelas (internal plus topical)" and the firm believes that "it is fair to assume the practicing physician may find it of value in the treatment of many other germ diseases, perhaps in cholera, small pox and others." No evidence was submitted in support of these sweeping recommendations, nor was any evidence offered in support of the claim that the removal from the official creosote of any monohydric phenols that may be present permits the administration of unusually large doses of creosote.

Callaway's Creosote, de-mono-hydrated, is unacceptable for inclusion in New and Nonofficial Remedies because it is a preparation of indefinite composition offered with unwarranted claims under a proprietary name which is not descriptive of its composition.

### PEPTO-SALICYLAS COMPOUND NOT ACCEPTABLE FOR N. N. R.

Pepto-Salicylas Compound is stated by the proprietors, the Curtis Pharmacal Company, Denver, to be "a mixture, containing in each fluid ounce Salicylic Acid, thirty grains,—Phosphate of Iron,—eight grains, Phosphate of Soda, one hundred and five grains,—Pure Pepsin, six grains, and Colchicine one sixty-fourth grain, in aqueous solution, with one minim Fluid Cardamon Compound to the ounce as flavoring." The label on the trade package declares the amount of salicylic acid that is in the mixture but does not declare the amounts of any of the other ingredients.

The proprietors state that Pepto-Salicylas Compound is a "Uric Acid Solvent and Eliminant" and that the mixture is indicated in the treatment of "rheumatism fever, muscular and articular rheumatism, and for pain attending Arthritis." According to the label the mixture is "an agreeable and promptly efficient preparation of TRUE SALICYLIC ACID, in which proper combination and accurately balanced proportion obviate the gastric irritation usually encountered" and the mixture is stated to be "An eligible Vehicle for the Iodides." There is no reason to believe that the several components of this mixture will mitigate in any way the characteristic effects of salicylic acid when administered in the form of sodium salicylate: on the contrary, the other ingredients are a hindrance to the intelligent use of salicylates and the combination of colchicine with salicylates is irrational. The statement that this complex mixture is "an eligible vehicle for the Iodides" is an unwarranted recommendation for the administration of this salicylate preparation as a routine when iodides are given. As a vehicle for the administration of iodides there is nothing superior to an abundance of pure water as a diluent.

The Council finds Pepto-Salicylas Compound unacceptable for New and Nonofficial Remedies because it is a complex, unscientific mixture marketed with unwarranted claims under a name not descriptive of its composition, and without a declaration on the label of the amounts of the potent ingredients other than the salicylic acid claimed to be present, which are contained in it.

# Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## PORTOLA BRAND CALIFORNIA TUNA

(Extra Fancy) (Packed in High Grade Salad Oil)

*Manufacturer.*—K. Hovden Company, Monterey, Calif.

*Description.*—Canned cooked light meat of Yellowfin Tuna with added salt, refined cottonseed oil and sour pickle.

*Manufacture.*—Tuna fish are harvested from 300 to 500 miles off the coast of Mexico. For this brand, small (15 to 60 pounds) Yellowfin Tuna only, the most solid and tasty of the tuna species, is used. The fish are packed in ice immediately after catching and kept in refrigerator ships until delivered to the factory. All fish are inspected by the state board of health inspectors before they are taken into the plant. The inspected fish are eviscerated, washed with brushes, laid in baskets, cooked in closed cookers under pressure for three to five hours, cooled, brought to a cleaning table, cleaned, boned, cut into quarters, the brown meat is scraped away and the light meat only is used. The light strips of meat are carefully laid into trays, cut into chunks of proper size by a perforating machine to fit the cans and placed in cans, effort being made to retain the chunk in one piece. A proper quantity of salt, refined cottonseed oil and a piece of sour pickle are added on the bottom and top of the can. The cans are sealed and heat processed in retorts under the supervision of the state board of health both as to temperature and as to length of time of heating.

*Analysis* (submitted by manufacturer).—

| (analysis of entire can) | per cent |
|---|---|
| Moisture | 55.1 |
| Ash | 2.3 |
| Chlorides as sodium chloride | 1.4 |
| Fat (ether extract) | 17.9 |
| Protein (N × 6.25) | 24.6 |
| Glycogen | trace |
| Crude fiber | 0.02 |
| Carbohydrates (by difference) | 0.1 |
| Iodine (I) | 0.0001 |

*Calories.*—2.6 per gram; 74 per ounce.

*Claims of Manufacturer.*—These California tuna are for all table uses. A dietary source of iodine.

## REPORTS OF THE COMMITTEE

The Committee has authorized publication of the following report.

Raymond Hertwig, Secretary.

### "SWEANEY'S BUTTER KRUST BREAD" NOT ACCEPTABLE

Sweaney's Bakery, Canton, Ohio, submitted to the Committee on Foods a white bread called "Sweaney's Butter Krust Bread. This bread is prepared by the sponge dough method from patent flour, water, yeast, salt, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride, and potassium bromate, sucrose, lard, sweetened condensed skim milk and a hydrolyzed starch.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 36.0 |
| Ash | 1.2 |
| Fat (ether extraction method) | 1.0 |
| Protein (N × 6.25) | 9.4 |
| Crude fiber | 0.1 |
| Carbohydrates other than crude fiber (by difference) | 52.3 |

*Discussion of Name and Label Statement.*—The name "Sweaney's Butter Krust Bread" indicates either that the baking formula contains sufficient milk-fat or butter or that the bread crust has been specially treated with butter to impart to it a distinctive and characteristic butter flavor. Butter, however, is not an ingredient of the bread; furthermore, skim-milk and not whole milk is used in the baking formula. Neither the bread nor the crust has any detectable characteristic butter flavor. The name is considered inappropriate for the bread, and is misinformative and misleading.

The label statement "Is made with milk" is incorrect in that skim-milk and not milk is an ingredient; further, the statement implies that milk is used in place of water in the preparation of the bread dough, making the product a "milk bread," which is misleading.

The manufacturer when informed of this opinion expressed himself as unwilling to change the name or correct the label statement in accordance with the Committee's recommendations. This bread therefore cannot be listed among the Committee's "accepted" foods.

## GENERAL COMMITTEE DECISIONS

The Committee on Foods authorizes the publication of the following General Committee Decisions adopted for its own guidance and for that of food manufacturers and advertising agencies on food advertising.

Raymond Hertwig, Secretary.

### TESTIMONIALS OF A MEDICINAL OR THERAPEUTIC CHARACTER IN FOOD ADVERTISING

Testimonials of a "health," medicinal or therapeutic character, or with such implication, in food advertising by persons unqualified to express a scientific authoritative opinion or judgment on the subject of the testimonial are misleading or deceptive and are not permissible. Testimonials accompanied by the writer's name and used with his permission will be considered as to their acceptability *in* individual instances.

### ACADEMIC TITLES "DOCTOR" AND "M.D." AS INTEGRAL PARTS OF NAMES OF FOODS

Names of foods including the academic titles "Doctor" or "M.D." accompanied or unaccompanied by the name of a person lend themselves to misleading or deceptive advertising of a medicinal, quasimedicinal or therapeutic character and are not permissible. No objection will be taken to such names for products that have been on the market at least ten years before the institution of this rule (April 15, 1932).

### SUPERLATIVE AND COMPARATIVE CLAIMS

Objection will not be made to superlative and comparative claims without specific scientific or technical significance and which are overtly recognizable as without definite meaning provided they are not deceptive or misleading. Statements expressing or inferring exactness of comparison which is not scientifically or technically warranted or in accord with fact are not permissible.

*"One of the best"* instead of *"the best"*; *"an ideal"* instead of *"the* ideal"; *"one* of *the* richest" instead of *"the* richest"; and similar forms of expression exemplify possible acceptable claims in instances in which the specific superlative statement is not permissible.

### THE CLAIM "RECOMMENDED BY PHYSICIANS" AND EQUIVALENT STATEMENTS

The claim "recommended by physicians" and statements of similar import in food advertising are vague in meaning, usually assumed, have no factual significance, convey misleading implications of nutritional or therapeutic values, and therefore are not allowable. Proper and correct recommendations by food manufacturers for specific uses of their products or signed statements based on specific studies by recognized authorities are permissible.

### AMBIGUOUS AND INCORRECT USE OF THE TERM "ADEQUATE" IN FOOD ADVERTISING

The term "adequate" in connection with vitamin, mineral or other nutritional claims in food advertising shall be used with its correct scientific significance. The term is permissible only in connection with definite and stated quantities of food containing the adequate quantity and then only when the claim for adequacy is supported by established knowledge.

## RATE OF HEALING OF BONE FRACTURES

The inevitable wear and tear to which the organism is subjected during life raises the mechanisms of defense and the processes of repair to a position of great importance. Attention has been called repeatedly to the details of such activities as the clotting of blood, the regeneration of nerves, the healing of superficial wounds and the restitution of functional hepatic tissue. Not only has the process itself been described, but factors that facilitate or retard it have been studied. Thus, much attention has been directed to the importance of sterility in the healing of wounds and, during recent years, the influence of diet has been extensively investigated. In view of the increase of accidental injuries correlated with modern life, it is not surprising that studies of the reparative processes in the body have found application in the clinic. It should not be overlooked, however, that much of the finer detail and relationships of the mechanisms of repair have been worked out through the use of experimental animals in the laboratory. In a recent study, McKeown, Lindsay, Harvey and Howes[1] have determined the rate of healing of fractures and certain related factors.

In this investigation, particular care was used to maintain the experimental animals (albino rats) under uniform dietary conditions. In one group the fibula of the right hind leg was fractured and allowed to heal. At stated intervals these rats were killed and the breaking strength of the callus was determined. This was compared to the breaking strength of the intact left fibula of the same animal as well as to that of the fibula of control animals without preliminary fractures. It was observed that the breaking strength of the fibula of the control rats was directly correlated with the length of the bone and with the body weight of the animal. The food intake and body weight of this control group decreased slowly in the course of the study and there occurred a diminution in breaking strength of the intact fibula, which roughly paralleled this decrease. Since the length of the experimental period was only forty-five days, it appears that the observed tendency of the breaking strength to decrease was associated with nutritive condition rather than with age.

The diameter of the callus of the broken bone, as seen in roentgenograms, increased progressively from the sixth postoperative day to the fifteenth. Apparently during this time salts were being laid down in the callus, although the depositions were noticeably irregular. At the same time there occurred a decalcification of the fractured surfaces. The breaking strength of the callus increased sharply to the fifteenth day, then decreased to the twenty-first day, and finally showed an increase to the forty-fifth day. Histologic examination of the callus indicated that the period of weakness between the fifteenth and the twenty-first day was associated with the fusion of the ingrowing blood vessels whereby the medullary space is formed. Subsequent thickening of the cortex and reorganization of the callus was correlated with the increased breaking strength after the twenty-first day.

It was further observed that the unfractured left fibula showed parallel variations in breaking strength with those of the callus of the fractured bone. This observation was found true of the breaking strength of the radii of the same rat. Whereas it has been shown that, under stress, the osseous tissue acts as a readily available reservoir for the characteristic mineral salts, it would appear from these studies that, under the particular experimental conditions imposed, there is a general response on the part of the body as a whole to the requirements in a local situation, and that this response is motivated through a mechanism which is not highly selective.

## GRAPES AND URINARY ACIDITY

One of the contributions made by biochemistry during the present century is the demonstration that the reaction of the foods which we eat, that is, their immediate acid or alkaline character, is by no means a dependable index of their behavior in metabolism. Citrus fruits, for example, are acid when tested by the usual methods employed by chemists for this purpose. They exhibit marked acidity toward litmus or many others of the various indicators in current use. This result is due to the well known presence of organic acids, notably citric acid, in such edible products. These acids are, as a rule, oxidized in the body, leaving a residue of basic ingredients to be disposed of. Hence there exists the seeming paradox that an acid food may be potentially alkaline, so far as its behavior in the organism is concerned. On this account it is readily possible to bring about with acid fruit juices metabolic consequences that are quite like those induced by the alkaline sodium bicarbonate. Sodium citrate is a potential alkali in the organism; it is now occasionally used in place of sodium bicarbonate when there is a desire to induce alkalization.

---

[1] McKeown, R. M.; Lindsay, M. K.; Harvey, S. C., and Howes, E. L.: The Breaking Strength of Healing Fractured Fibulae of Rats, Arch. Surg. 24: 458 (March) 1932.

These now well known reactions have directed attention to the consideration of foods as potentially alkaline or acid. Protein foods and cereals as a rule give rise to acid end-products in the body; fruits and vegetables tend to be potentially alkaline. Milk, "the most nearly perfect food," is intermediate in its effects. True acidosis can therefore be combated by the ingestion of potentially alkaline foods, even though they are naturally acid in reaction; and the reverse is true of alkalosis. The urine of herbivorous animals is normally alkaline; that of carnivorous species is unmistakably acid as a rule. The capacity of the organism to oxidize organic acids in the way referred to is quite remarkable. For example, Blatherwick and Long[1] have reported that even when large amounts of acid orange juice are ingested there is a production of alkaline urine. They state that it was impossible to overreach the organism's ability to oxidize the contained citric acid even though the amounts of orange juice drunk in one day were the equivalent of 48 Gm. of acid. The excess of base in the orange juice in Blatherwick's experiments was sufficient to balance the organic acidity that escaped oxidation and to cause an alkaline urine, as well as a marked depression in the excretion of ammonia.

There are, however, a number of organic acids that occur naturally in foods and are not so readily oxidized. Oxalic acid is an extreme illustration. Benzoic acid and its salts are conjugated in the body with glycine to form hippuric acid. Tartaric acids have been reported to exhibit considerable resistance to oxidation. Grapes are notably rich in tartrates, grape juice forming a familiar source of "cream of tartar." There has accordingly been some doubt as to the behavior of grapes and grape juices from the standpoint of their potential reaction in the body. An elaborate study of this problem has been reported by Saywell[2] from the University of California College of Agriculture at Berkeley. It included observations of persons on a control diet and on the same "basal" regimen supplemented by fresh grapes, fresh natural grape juice, detartrated grape juice, natural grape juice concentrate, concentrate-tartrate mixture, Thompson seedless raisins and Muscat seeded raisins. An increase in the urinary hydrogen ion concentration occurred, ranging from 0.8 to 1.2 $p_H$ units. A decrease in the ammonia excreted and a corresponding decrease in the total acidity were noted. There was an increase of the alkali reserve above the normal for each person. A correlation between the alkalinity of the ash and the physiologic reaction was apparent. Grapes and grape products with the greater alkalinity of ash were associated with a more basic body reaction. An increase occurred in organic acids excreted. This may be explained by the presence in the urine of some incompletely oxidized tartaric acid. The most surprising feature, however, is that considerably more than 90 per cent of the organic acids ingested in grape products, sometimes exceeding 30 Gm. (1 ounce) was oxidized in the body as a rule. The crucial physiologic experiment thus shows that grapes and their derivative products behave like many other fruits in the body. Nevertheless, as 2 Gm. or more of the ingested acids of grapes was often excreted unoxidized, the possible nephrotoxic action of even such small quantities of an incriminated acid cannot be overlooked. Until further evidence is forthcoming, one may therefore question the physiologic advisability of the continued use of large quantities over long periods of time.

## SCHÜLLER-CHRISTIAN DISEASE—A DISTURBANCE OF THE LIPID METABOLISM

About forty years ago, Hand discussed in the Transactions of the Philadelphia Pathological Society a peculiar clinical and anatomic picture characterized by xanthomatous lesions of the bones and polyuria. Since the case also presented signs of tuberculosis, he considered the xanthomatous changes tuberculous. Hand's observations were apparently not repeated until more than twenty years later. Then Schüller called attention to sharply defined geographic defects of the skull in young persons, with signs of dyspituitarism. A similar combination was observed by Christian, who outlined a symptom complex consisting of defects of the membranous bones, diabetes insipidus and exophthalmos. Cases more or less related to those described by Hand, Schüller and Christian had been published from time to time under different names and had been interpreted as being granulomatous or blastomatous in nature. With an intuitive feeling for causal relations, Rowland collected this material, grouped together the common features and, basing his analysis on the careful study of two cases in his own experience, established the anatomic background for a disease entity. He demonstrated that osseous defects, dyspituitarism and exophthalmos had a common cause; namely, the formation of xanthomatous lesions in the dura mater and about the infundibulum of the brain. To this osseous form of xanthomatosis the name "Schüller-Christian disease" has been given.

The modern clinical and pathologic-anatomic literature contains many observations which indicate that the xanthoma is really the local manifestation of a disturbed lipid metabolism. Thus, Schüller-Christian disease becomes related to the other well defined disturbances of the lipid metabolism, in particular to Gaucher and to Niemann-Pick disease. According to our present knowledge the essential difference between the three diseases seems to be the chemical nature of the lipid substance, which is either formed or retained in excessive amounts and becomes deposited in the tissues, especially those with the greatest storing ability (the cells belonging to the reticulo-endothelial system). In Gaucher disease, the cerebroside kerasin is deposited in the liver, spleen, lymph nodes and bone marrow. In Niemann-Pick disease, excessive amounts of phospholipids appear in practically every organ of the body, including the brain. The characteristic lesions of Schüller-Christian disease are rich in cholesterol and cholesterol esters (E. Epstein).

---

[1] Blatherwick, N. R., and Long, M. Louisa: Studies of Urinary Acidity: I. Some Effects of Drinking Large Amounts of Orange Juice and Sour Milk, J. Biol. Chem. 53:103 (July) 1922; II. The Increased Acidity Produced by Eating Prunes and Cranberries, ibid. J. Biol. Chem. 57:815 (Oct.) 1923.

[2] Saywell, L. G.: The Effect of Grapes and Grape Products on Urinary Acidity, J. Nutrition 5:103 (March) 1932.

In a recent exhaustive review of the anomalies of the lipid metabolism,[1] Rowland submits a tentative classification of these anomalies which should prove useful for further investigations. He distinguishes between essential or primary disturbances of the lipid metabolism, which include essential xanthomatosis, Schüller-Christian disease, Niemann-Pick disease and Gaucher disease, and symptomatic or secondary disturbances, which are observed in diabetes mellitus, icterus, pregnancy, menstrual anomalies and renal diseases. Though the clinical and anatomic picture of these conditions is well established, much further work is required in order to disclose the nature of the biochemical processes that lead to their manifestations.

## *Current Comment*

### PARTURITION AND THE POSTERIOR HYPOPHYSIS

The demonstration of the marked physiologic potencies of epinephrine early led many students of endocrine function to the conclusion that the suprarenal medulla is indispensable to life. It was known that in suprarenal disease low blood pressure is often a characteristic symptom; and as epinephrine is extremely potent as a pressor substance, what could be more logical, seemingly, than to assume that the hypotension attending suprarenal destruction is due to a lack of epinephrine from the medulla? However, the hypothesis failed to be supported by the actual experiments. Epinephrine *does not supply complete replacement therapy* following removal of the suprarenals. Furthermore, there is conclusive evidence that the cortex of the suprarenals, rather than the epinephrine-secreting medulla, is the truly indispensable part of these structures. Removal of the medulla is not necessarily fatal; but loss of the suprarenal cortex results in death unless the newly investigated cortical hormone is supplied. A somewhat similar upset of an attractive hypothesis seems to have been made recently by studies of the posterior hypophysis. The effectiveness of extracts of this structure in strengthening the uterine contractions of parturition are well known to clinicians. The pharmacologic observations have made it seem probable to some observers that the posterior lobe plays an important or even essential part in the initiation and completion of this process. Experimental proof of the liberation of unusual amounts of the oxytocic principle of this lobe, especially into the cerebrospinal fluid at the termination of pregnancy, has even been claimed by a number of investigators. The crucial experiments have been undertaken by P. E. Smith[1] of the College of Physicians and Surgeons at Columbia University. The posterior hypophysis was removed in adult female animals and the effect on parturition noted. The completeness of the ablation was verified by a microscopic examination of serial sections of the pituitary capsule and its contents. In all cases some anterior lobe tissue also was removed, but a sufficient amount remained to maintain normal body growth and sex cycles. Six of these animals were mated and bore litters. Birth occurred at the usual time. The evidence thus shows that at least in the species studied a secretion of the posterior hypophysis is unnecessary for either the onset or the maintenance of the uterine contractions at parturition. Of course, such experiments do not negate the value of the familiar extracts in promoting uterine contractions or the possibility that oxytocic hormones may be supplied by other tissues.

### GRAVITATIONAL SPREAD OF LOCAL INFECTIONS

The pneumococcus forms an antithrombic substance which facilitates the spread by gravity of infected transudate throughout the lungs. The suggestion that this gravitational spread may be inhibited by intravenous injection of prothrombic agents is made in a recent report of research at the Rockefeller Institute. In order to study the mechanical factors in pneumococcic infections, Goodner[1] inoculated rabbits intradermally well up on the flank with virulent pneumococci; thus he produced a "dermal pneumonia . . . basically similar to the pulmonary lesion." The resulting dermal lesion was characterized by copious edema, the local transudate gradually spreading ventrally as a result of the gravitational factor. By mechanical drainage, from 5 to 10 cc. of the edematous fluid was obtained for serologic study. This fluid was found not only noncoagulable but capable of inhibiting normal blood coagulation. A thromboplastic substance added to the fluid, however, restored normal plasma coagulation. The local injection of the thromboplastic substance was therefore tried and was found to prevent the gravitational spread of the edematous fluid. Hourly intravenous injections with the thromboplastic substance were tried and were found effective in holding the gravitational spread in check. "Within two hours after discontinuation" of this intravenous prothrombic therapy, "the edema fluid began to move ventrally at the usual rate." While Goodner has not yet suggested a clinical application of this method, it seems to open a promising line for further research in experimental laboratories.

# PROCEEDINGS OF THE NEW ORLEANS SESSION

## MINUTES OF THE EIGHTY-THIRD ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, MAY 9-13, 1932

*(Concluded from page 1820)*

## *Second Meeting—Tuesday Morning, May 10*

The House of Delegates was called to order at 9:30 a. m. by the Speaker, Dr. F. C. Warnshuis.

It was moved by Dr. Arthur J. Bedell, New York, seconded by Dr. J. W. Van Derslice, Illinois, and carried, that the signed attendance slips constitute the roll call of the House.

Dr. William H. Mayer, Pennsylvania, moved that the House dispense with the reading of the minutes. The motion was seconded by Dr. C. S. Gorsline, Michigan, and carried.

### Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported that 149 delegates had filed satisfactory credentials.

The Speaker, hearing no objections, declared that the report of the Reference Committee on Credentials would be received.

### Report of Board of Trustees

Dr. Edward B. Heckel, Chairman, presented the following report:

1. Relative to the resolution presented by Dr. Gorsline of Michigan, the Board of Trustees reports that it has been giving every possible aid to the Bureau of Medical Economics in order to enable that bureau to secure and publish information on the subjects mentioned, and that as it becomes apparent to the Board that increased budget and personnel are needed, the Board of Trustees will attempt to provide what is necessary.

2. The Board of Trustees favors the recommendation contained in the resolution introduced by Dr. William R. Molony, California, relative to gathering and publishing in book form the legal decisions published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from week to week. The Board feels, however, that these should be provided to the constituent state associations at cost.

3. Relative to the resolution introduced by Dr. Edgar A. Hines, South Carolina, the Board of Trustees reports that careful consideration was given to the matter of reducing the subscription price of THE JOURNAL before Dr. Hines' resolution was introduced as well as on other occasions, and it was not deemed wise or expedient to make any reduction at the present time.

Dr. C. S. Gorsline, Michigan, moved the adoption of the first section of the report, with respect to aid for the Bureau of Medical Economics. The motion was seconded by Dr. B. F. Bailey, Nebraska, and carried.

On motion of Dr. Arthur J. Bedell, New York, seconded by Dr. H. B. Everett, Tennessee, and carried, the second section of the report relative to publication of legal decisions was adopted.

Dr. Wells Teachnor, Sr., Ohio, moved the adoption of the third section of the report concerning reduction in subscription price of THE JOURNAL. The motion was seconded by Dr. B. F. Bailey, Nebraska, and carried.

On motion of Dr. Arthur J. Bedell, New York, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the report of the Board of Trustees was adopted as a whole.

### Report of Reference Committee on Legislation and Public Relations

Dr. Grant C. Madill, Chairman, presented the following report:

The meeting of the Reference Committee was held immediately after the adjournment of the morning session, every member of the committee being present.

1. Resolutions introduced through the secretary of the Michigan State Medical Society concerning the effect of doles and federal health and sick benefit appropriations were read and, after discussion, it was decided to approve of securing data bearing on the question and submit such information to the Board of Trustees.

2. The committee then considered the resolution introduced by Dr. Shoulders concerning the Veterans' Hospitalization Act, which elicited free discussion. It was decided to refer the question to the Committee on Legislative Activities and its Auxiliary Committee on Veterans' Legislation.

GRANT C. MADILL, Chairman.
JOHN F. HAGERTY, Secretary.
SOUTHGATE LEIGH.
C. J. WHALEN.
A. A. ROSS.

The first section of the report was adopted on motion of Dr. Madill, seconded by Dr. Albert E. Bulson, Indiana, and carried.

Dr. Madill moved the adoption of the second portion of the report. The motion was seconded by Dr. Arthur W. Booth, New York, and carried.

On motion of Dr. Madill, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the report of the Reference Committee on Legislation and Public Relations was adopted as a whole.

### Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr. N. B. Van Etten, Chairman, presented the following report:

1. Your Reference Committee on Amendments to the Constitution and By-Laws has carefully considered the proposal of Dr. D. E. Sullivan, New Hampshire, to amend section 2 of article 5 of the Constitution so that the section shall read as follows:

> The House of Delegates is composed of delegates elected by the constituent associations and by the sections of the Scientific Assembly, and of delegates from the medical departments of the Army and the Navy and the Public Health Service and Veterans' Bureau appointed by the Surgeon-General of the respective departments and by the Medical Director of the Veterans' Bureau. The Trustees, the ex-Presidents of the Association and the members of the several councils shall be ex officio members of the House of Delegates without the right to vote, provided that members of the Councils who are also elected delegates may exercise all of the rights of elected delegates.

Under this proposed amendment the Medical Director of the United States Veterans' Administration would be made a member of the House of Delegates.

Your Reference Committee believes that the designation of any one individual, regardless of qualifications, as a member of the House of Delegates violates the democratic principles on which the House of Delegates is organized.

Your Reference Committee further believes that the fact that only 457 of the 1,668 full time physicians who are members of the United States Veterans' Bureau, have membership in the American Medical Association, that only 257 of them are sufficiently interested to become Fellows of the American Medical Association, and that these members are distributed among forty-one constituent organizations, furnishes sufficient reason for denying special representation in the House of Delegates and therefore your Reference Committee disapproves this proposal to amend the Constitution.

2. Your Reference Committee believes that sections 1 and 2 of chapter XI of the By-Laws on membership and Fellowship in the American Medical Association are sufficiently

definite in their provisions concerning dual memberships and that strict observance of these provisions should be insisted on.

3. Your Reference Committee approves the recommendation of Dr. Isaac A. Abt, delegate from the Section on Diseases of Children, to amend section 1 of chapter XIV of the By-Laws by changing the title of the Section on Diseases of Children to Section on Pediatrics, substituting the word "Pediatrics" for the words "Diseases of Children."

N. B. Van Etten, Chairman.
J. W. Amesse.
John H. O'Shea.
H. M. Johnson.
Walter F. Donaldson.

On motion of Dr. Van Etten, duly seconded and carried, the first section of the report disapproving the amendment to section 2, article 5 of the Constitution was adopted.

Dr. Van Etten moved the adoption of the second section of the report. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

It was moved by Dr. Van Etten that the third section of the report amending section 1, chapter XIV, of the By-Laws be adopted. The motion was seconded by Dr. J. W. Burns, Texas, and carried.

Dr. Van Etten moved the adoption of the report as a whole. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

It was moved by Dr. Van Etten that the By-Laws be amended so that the Section on Diseases of Children be now designated "Section on Pediatrics." The motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

### Report of Reference Committee on Sections and Section Work

Dr. F. W. Cregor, Chairman, presented the following report:

Mr. Speaker, your Reference Committee on Sections and Section Work, to which was referred the report of the Council on Scientific Assembly, excepting only that portion of the report having to do with amendment to the By-Laws, expresses its appreciation of the Council's program on scientific presentations. Fully understanding the immensity of their task in selecting lecturers of known skill to address the general assembly and the careful elimination of the sensational, we most heartily endorse its work.

F. W. Cregor, Chairman.

On motion of Dr. Cregor, seconded by Dr. Arthur J. Bedell, New York, and carried, the report was adopted.

### Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. W. F. Braasch, Chairman, read the report of the Reference Committee on the Report of the Secretary, and moved its adoption. On motions, seconded and carried, each section of this part of the report was adopted.

Dr. Braasch read the report of the Reference Committee dealing with the report of the Board of Trustees, consideration of which was postponed until the Executive Session of the House on motion of Dr. Walter F. Donaldson, Pennsylvania, seconded by Dr. William G. Ricker, Vermont, and carried.

### Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, stated that Dr. J. J. Moore, who is the alternate delegate for Dr. D. J. Davis of the Section on Pathology and Physiology, presented no credentials whatever, but had been certified to by Dr. West. He moved that the House of Delegates seat Dr. Moore. The motion was seconded by Dr. William H. Mayer, Pennsylvania, and carried.

### The Surgeon General's Library

The Speaker introduced Gen. R. U. Patterson, Surgeon General of the United States Army, who addressed the House as follows:

*Mr. Speaker, Members of the House of Delegates of the American Medical Association:*

I am here today through the courtesy of the officers of your House of Delegates for the purpose of bringing to your attention the action of this body last June in Philadelphia, which, if it remains on your records unchanged, will result in doing a great injury to the medical education program of the Medical Department of the Army, and also will have an effect which you do not desire on the medical profession of the country itself. Without any further preliminaries, and knowing that your time is valuable, I will go into the matter as briefly as possible.

The Army Medical Library, commonly called the Surgeon General's Library, was started by Surgeon General Lovell in 1818. It never amounted to very much until after the Civil War. At the time of the Civil War there were some 500 or 600 volumes in the whole Army Medical Library. However, at that time the Surgeon General, General Barnes, allocated $80,000 of unallocated funds to the library for the purchase of books. The late distinguished and versatile medical man Colonel John S. Billings became librarian of the Surgeon General's Library, and under him it had an unprecedented growth and became one of the great libraries of the world. In the early eighties, $200,000 was expended on the present buildings in which the library and the museum of the Army are located.

There has always been plenty of advice available to the Surgeon General of the Army and the librarian of the library to assist them in the best policies and plans to follow out in the development of that library. I may say that while it should never be done officially without an act of Congress, the present Surgeon General, and I am sure all those who follow him, fully intend to seek the best advice that can be obtained in this country from those who are familiar with libraries, and with medical libraries in particular, and it is my intention to have what will be always an unofficial committee, but nevertheless a most effective one, to guide us and help us whenever we need counsel.

There are today some 409 incunabula and some 260 other rare books, all prior to the year 1525. The present contents of the library are 333,202 bound volumes, 47,171 unbound volumes, and 509,304 pamphlets; that is, there were on April 29 of this year a total of 889,677 publications in the Surgeon General's Library.

In 1879 the Surgeon General's Library began to publish what was known as the *Index Medicus*. Through lack of funds in recent years it was turned over in 1927 to the American Medical Association, which now publishes it as a part of the *Quarterly Cumulative Index Medicus*. In 1880 the compilation of the *Index Catalogue* was begun by the library and has been continued ever since. They have just completed the ninth volume of the third series of this catalogue. The tenth is about to be published. The last one cost some $22,107 and a few odd cents. The next volume will be more costly and will embrace in it information that has never been placed in one volume; it has been scattered heretofore in the whole series as they were published. Hereafter, though, in the tenth volume you will find listed by name all the incunabula and the rare books.

At the present time the Surgeon General's Library, I believe, is the largest collection of medical works in the world. There is a question about that; we are not sure that the library in Paris may not have more volumes, but they don't know themselves what they have got.

The Medical Department of the Army has always recognized, since its inception, the idea of an army medical library as a national asset and as a trust held by them for the whole profession of the country. However, in that connection it is proper to mention the fact that the Medical Department of the Army was in existence for seventy-odd years before we had an American Medical Association, and that the library was started thirty-five years before the American Medical Association was actually organized in 1847. I simply throw that out as an indication of the fact that we started it and have taken care of it for 112 years.

There has always been an earnest desire on the part of everybody in the Medical Department to make that library useful not only to the profession in this country but to the world. Previous to the war we didn't have a very liberal policy. Our policy was that of most libraries, particularly the Library of Congress; books were not sent out. Men had to come to Washington and consult the works in the library itself, but a much more liberal policy was started during the war and it has become a lending library in its principal activity. For instance, during the last year more than 11,000 volumes were sent out to some 308 libraries throughout the country, so that anybody who wants to get a book does not need to come to Washington unless he wishes to consult one of the incunabula.

The library is an absolutely essential part of our medical educational system in the Army. It is utilized freely by the officers of the Medical Corps of the Navy, of the Public Health Service, of the Veterans' Administration, and by the physicians who are members of the Medical Society of the District of Columbia.

There has been a complaint made on one or two occasions that the library was not open at night. Gentlemen, it doesn't make a bit of difference whether we have it or the Library of Congress has it, whoever has it can keep it open at night only if there are more funds made available for the employment of personnel. There is a far greater chance of our being able to keep it open without additional expense at the Army Medical Center, where we have lots of enlisted men, than there is of its ever being kept open in any other location in the city of Washington without very much increasing the funds for the employment of personnel.

Congress has repeatedly recognized the value of the library of the Surgeon General's Office.

About thirty years ago, the dean who has just retired from George Washington Medical School, Dr. Boyden, conceived the idea of a great army medical center at the capital of the nation, something better than we have in any country in the world. They made their plans. The idea was to have first a large hospital as the clinic, and then the Army Medical School and the veterinary and dental schools, which, as you know, are postgraduate schools, and then the library and the museum alongside, making a complete institution. Today the essential buildings of the Walter Reed General Hospital have been completed. The Army Medical School and the veterinary and dental schools (and they are very handsome buildings) have just been completed. The Army Medical School has been in operation in its present building since 1923, but these other buildings have been built, the additions have been put on, and it is now complete. The only thing we lack to make the center complete is the Army Medical Library and the Army Medical Museum.

In these times it is hard to predict when we will get that money, but the influence, moral and otherwise, of an association like this can assist us very much in getting that money when the time is ripe in this country.

Last June certain gentlemen were interested in the library, and I know they meant the very best in the world. But I think they did what I consider was an extraordinary thing.

I was in Philadelphia myself at your last meeting and would have been more than willing and glad to have an opportunity to say something on the action that was taken. However, though we were the greatest and the most concerned of anybody, we weren't consulted, and your body passed a resolution which will potentially do us great harm, and the record will prove the fact that the American Medical Association desires to have our library placed somewhere else, where it will do us no good and do you some harm if you are interested in libraries.

I am going to state briefly just what happens if this thing prevails. First of all, that is our library. We originated it. We have cared for it and developed it for a hundred and twelve years, and the present resolution that stands on your books would take that thing away from us and put it up somewhere where we don't want it. It would be exactly as if some of you decided that you would prefer, when you go to Baltimore, to have a library down at the Union Station or at the Mount Royal Station, instead of going two and a half miles, probably, to the Johns Hopkins Hospital and the Medical School where the library is located, exactly near those buildings, where it is available and useful. That is a parallel of what you have unwittingly attempted to do to the Medical Department of the Army. It is the first time in my life, and certainly in my thirty-one years of service, that I have ever seen the American Medical Association apparently opposing something that is necessary to the Medical Department of the Army. It has never happened before, and I know it was not done advisedly.

The Planning and Beautification Committee of Washington is planning to beautify that city. We are in the way. Our location is not satisfactory; it will obstruct it. Furthermore, it is too small.

When the Army Medical School was started in 1893, it was with the Army Medical Museum. The library got too large and so did the museum. Finally we were located in the Army Medical Center, where the school is now. But to put it up in the Library of Congress or adjacent to it will make it necessary to condemn a site at great expense, because it is all built up around there, as you well know. Here we have a site available right across from the Army Medical School, and it has been available since 1922, when Congress, for a second time, appropriated funds for the purpose of purchasing land on which to place the Army Medical Library. Many of you know that place; if you do not, the next time you go to Washington, go up and see the school buildings and the hospital and look at the site immediately across the street. There is no finer site for the library. It is absolutely essential for our purposes. It would just ruin the Army Medical Center if we don't have it there. So much for the expense of the site.

If the building were erected near the Library of Congress it would mean that it must be built in harmony with the architecture of those federal buildings on that hill, a very much more expensive proposition than if it should be located where we want it and where it ought to be. The buildings of the Army Medical Center, as you know, are brick and will cost much less than if we have to put up a granite or stone building at the Library of Congress.

As to accessibility, in these days of travel, figures show that fewer and fewer men are coming and consulting that library in person. Most of those who come drive over in automobiles. If they are coming from the north or west, the Walter Reed is five miles out of the city from the center where it is now, and although the city has grown up all around it, it is still nearer Baltimore than it has ever been. There would be ample parking space there, which could not be provided adequately over near the Library of Congress.

Finally, if your motion remains unchanged, it may result in the plans of thirty years of the War Department being frustrated, and the library, originated, developed and cared for by the Medical Department of the Army, will be practically taken away from it for unjustifiable reasons.

Even if the proponents of this motion had thoroughly realized what they were doing, if they did realize it, and I doubt it very much, the Delegates did not, because that was referred to one of your committees here and it came back, as I understand, as a report of that committee, I think it was the Committee on Education, and the whole thing went through very hastily. I am sure that the House of Delegates did not realize just what it was doing to us.

What harm has been done already, if any? I myself have had to answer many, many letters on account of that action, both for the Secretary of War and the President of the Senate, and I would have for the Speaker of the House only he died, and Mr. Garner has been too busy since he got in Congress, since the House opening, to take any notice of that. But your action plays into the hands of a member of Congress who told me not many weeks ago, and General Ireland, that he is going to take the library away from us anyway. He doesn't care whether it hurts you or hurts the Army. He is not very friendly to the Army and he is going to do it willy-nilly. I imagine he is too busy now, but when he gets a little time on his hands I haven't any doubt that he will try to put that through Congress. So long as your action remains unchanged, you are playing right into his hands, and you will be doing a hurt that you never intended to do.

Mr. Putnam, the librarian of Congress, has said distinctly that he doesn't want it, that it will be uneconomical. He doubts whether the efficiency will be increased, and that for many reasons it should be retained as a specialized library, just as the Department of Agriculture library and the library of the Geological Survey, and there is another bureau in Washington that has an entirely independent library.

Since your action of last June I have had many expressions of regret from the groups in Baltimore, in Boston and in Philadelphia. I received a resolution dated Nov. 28, 1931, from the Mayo Library Committee, approved by the Board of Governors of the Mayo Foundation, in which they deplored very much that you had taken the action you did.

Finally, the members of the District of Columbia Medical Society, who were familiar with the library, passed a resolution, Jan. 6, 1932, in which they deplored such action and advocated that no such action be taken as was contemplated by the resolution passed by the House of Delegates last June.

That resolution went through hastily. As long as it remains on your records it has potential power to do us injury, which I know you do not intend to do. I hope that some one will get up and move for a recession or rescinding of the action that you took last June, as it will do us a great deal of help. I feel confident I can ask this great body to be ready to stand behind the Medical Department of the Army if it becomes necessary to combat, I may say, certain malign influences in Congress; I might say one influence; that is the only one whose plans will harm us seriously, and if they carry through will do you harm. Don't make any mistake that if it becomes incorporated into the Library of Congress you will never be able to get books from it. You will have to go to the library to see them.

I hope you will take action in this very body at this time. In conclusion, I wish to thank you for giving me this opportunity and also to say that I appreciate very much your patience in listening to me.

The Speaker referred the remarks and the request of General Patterson to the Reference Committee on Medical Education for consideration and recommendation, after discussion by Dr. H. G. Stetson, Massachusetts, Dr. Thomas S. Cullen, a Trustee, Dr. C. B. Wright, Minnesota, and Dr. W. R. Steiner, Connecticut.

### Resolutions on Site of Surgeon General's Library

Dr. Wright presented the following resolutions, which were referred to the Reference Committee on Medical Education:

Whereas, At the Annual Convention of the American Medical Association held at Philadelphia in June, 1931, the House of Delegates passed a resolution advocating that when the Army Medical Library has to be moved to a new site it be placed adjacent to the Library of Congress; and

Whereas, At that time the House of Delegates did not have before it complete information concerning this status of the Army Medical Library and the plans of the War Department with respect to the Library; and

Whereas, That information being now fully available, it is evident that any departure from those plans of many years' standing with respect to the future location of the Army Medical Library will seriously interfere with the proper development of the Army Medical Center in Washington and will also render it less useful to the medical profession of the country as a whole; be it

*Resolved*, By the House of Delegates of the American Medical Association in convention assembled, that the resolution of the House of Delegates in June, 1931, at Philadelphia, with reference to the location of the Army Medical Library be, and is hereby, rescinded; and be it further

*Resolved*, That a copy of this resolution be sent to the President of the United States, the President of the Senate, the Speaker of the House of Representatives, and the Secretary of War.

We recommend that the House of Delegates offer its cooperation in obtaining a suitable fireproof building to house these priceless volumes.

### Remarks of Dr. T. C. Routley

The Secretary presented Dr. T. C. Routley, secretary of the Canadian Medical Association, who addressed the House as follows:

*Mr. Speaker, Mr. President and Gentlemen:*

It gives me, indeed, a great deal of pleasure to come here this morning and present to you greetings from the Canadian Medical Association, of which body I have the honor to be General Secretary.

There is a story told up in our country about two railroads, one of which you no doubt have heard, the other I doubt you have heard of. One is called the Canadian Pacific Railway and the other is the Cumberland Railway. The Canadian Pacific Railway has many thousands of miles of rails. The Cumberland Railway is a little organization with five miles of rails.

The president of the Cumberland Railway decided one time that he would like to have a pass over the Canadian Pacific, so he went up to the then president, Sir William Van Horn, and presented his card as president of the Cumberland Railway. Sir William, in inviting him in, said, "I never heard of this railway."

He said, "Sir William, it is not as long as yours but it is just as wide."

The Canadian Medical Association, in stature, is dwarfed beside you, but in its ideals and aspirations for progressive medicine, I trust that it is just as wide. I know that our men always delight in coming to your meetings, and you have always extended to them, as you have to me, a most cordial invitation and a delightful welcome. On their behalf and on my own behalf I desire to thank you.

I hope that some day this great body will see fit to join hands with us and meet in Canada. We would give you a most cordial welcome, indeed.

### Report of Reference Committee on Rules and Order of Business

Dr. R. W. Fouts, Nebraska, read the following report of the *Reference Committee on Rules and Order of Business:*

This report deals with the report of the Judicial Council except that part which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Your Reference Committee endorses the sentiment expressed in the second paragraph of the Council's report, calling attention to the danger of attempting to overturn some of the older traditions by submitting untried methods of practice and suggests the continuance of this procedure.

Your Reference Committee likewise believes that the present Principles of Medical Ethics is adequate and should be strictly adhered to in dealing with "Patents and Perquisites."

Your Reference Committee calls attention to the incorrect address of Dr. Donald Macrae, Jr., deceased, and in order that the records may be correct, recommends that this be changed to Council Bluffs, Iowa.

Your Reference Committee also recommends that some suitable memorial be devised for those who die during their term of service as officers of the American Medical Association.

Respectfully submitted.

Bertram L. Bryant, Chairman.
R. W. Fouts, Secretary.

Dr. Fouts moved that the report be adopted. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

### Report of Reference Committee on Miscellaneous Business

Dr. James R. Bloss, Chairman, read the following report of the Reference Committee on Miscellaneous Business:

1. Your Reference Committee recommends that the Secretary of the Association be instructed to comply with the request of F. V. Cargill that a letter be written to the Woman's Auxiliary expressing the appreciation of the House of Delegates for the activities of the Auxiliary and that the Secretary write the letter as asked.

2. The resolution presented by Dr. W. R. Molony, California, in the opinion of your committee, should be referred to the Bureau of Medical Economics. Your committee recommends that the Bureau of Medical Economics secure the information required by the resolution and that the report of the information requested by the California Medical Association be given at the earliest possible moment.

Respectfully submitted.

James R. Bloss, Chairman.
H. B. Everett.
William R. Bathurst.

On motion of Dr. Bloss, seconded by Dr. Randolph Winslow, Maryland, and carried, the report was adopted.

## NEW BUSINESS

### Resolution on Approval of Standard Classified Nomenclature of Disease

Dr. Frederic E. Sondern, New York, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

Whereas, A standard classified nomenclature of disease has been compiled by the National Conference on Nomenclature of Disease; and

Whereas, The said national conference is composed almost entirely of delegates from national clinical societies and other interested organizations, including a delegate from the American Medical Association; and

Whereas, The said Standard Classified Nomenclature of Disease has been prepared through the joint efforts of these delegates and committees appointed by their parent organizations and has been unanimously approved by the assembled delegates; and

Whereas, The national conference is now seeking the approval of the nomenclature as published in preliminary form for this purpose, before the publication of an official edition for general use; and

Whereas, The official edition will be substantially the same as the preliminary edition, differing from it not in design but only to a small extent in detail; and

Whereas, The purpose of the said national conference is to provide a uniform authoritative standard of nomenclature of disease for use throughout the country; and

Whereas, The approval of the American Medical Association will materially further this worthy object; therefore be it

*Resolved,* That the American Medical Association approve the said Standard Classified Nomenclature of Disease and recommend its use as a standard throughout the United States.

### Resolutions on Closer Cooperation Between the County Societies and the American Medical Association

Dr. Southgate Leigh, Virginia, presented the following resolution, which was referred to the Board of Trustees:

Whereas, The profession is confronted with difficulties that are both serious and urgent; and

Whereas, There is pressing need for close and active cooperation on the part of all component societies, as well as the individual doctors; and

Whereas, With such earnest cooperation many problems may be readily solved; therefore be it

*Resolved,* By the House of Delegates of the American Medical Association that the officers and trustees of the Association be instructed to communicate with the various constituent state societies, advising them of the difficulties and suggesting that they take the following steps:

1. To keep in close touch with the national organization.
2. To strengthen the county society units, and as far as possible to arrange for an organization in each county in the state.
3. To continue with renewed energy the work of the various public relation committees in states and counties; and

*Resolved,* That the delegates from each state society present this matter vigorously and promptly to their respective organizations; and further

*Resolved,* That the officers and trustees communicate with the Woman's Auxiliary to the American Medical Association, requesting its continued active cooperation with the profession and urging that local auxiliaries be formed in connection with every county society.

On motion of Dr. J. W. Van Derslice, Illinois, seconded by Dr. Samuel P. Mengel, Pennsylvania, and carried, the meeting recessed at 11 o'clock to reconvene at 1:30.

---

## *Third Meeting—Tuesday Afternoon, May 10*

The House of Delegates was called to order at 1:30 p. m. by the Speaker, Dr. F. C. Warnshuis.

### Report of Reference Committee on Medical Education

Dr. Irvin Abell, Chairman, presented the following report:

1. The Reference Committee has fully considered the report of the Council on Medical Education and Hospitals and desires to offer its commendation on the excellence of the amount of work detailed therein.

It is gratifying to note that cooperation of all but one of the acceptable medical schools was secured in publishing a record of the hospital training of their graduates, affording a distinct stimulus to graduate or fifth year education. The discouragement of the graduation of unqualified students is approved. It is suggested that a copy of the graphic chart on page 109 of the Handbook, showing the percentage of "repeaters," be sent to the schools listed therein.

It is further suggested that the resolution of the Council pertaining to the classification of foreign schools be affirmed.

The certification of specialists presents a problem of great practical importance and offers many angles to which the Council is devoting study but on which it is not yet prepared to make recommendations.

It is interesting to note that the number of medical graduates in the United States shows a steady increase, representing about 50 per cent more than the loss by death of the medical profession each year.

The hospital statistics presented by the Council show the results of decidedly active supervision with the resultant desire on the part of governing boards to comply with the essentials for registration and as well of an appreciable number for approval for internships and for residency in specialties; 6,612 are now on the register, while 684 have been approved for internships and 371 approved for residencies in specialties, offering at the present time facilities in graduate training in excess of the demand.

With the view of correlating hospital activities to meet the requirements of today to the end that its benefits may accrue in greatest measure both to the physician and the patient, the Council on Feb. 14, 1932, amended the "Essentials of a Registered Hospital" as adopted by the House of Delegates in 1928 and requests approval of these "Essentials" in the form submitted in supplement A, page 115, of the Handbook. The Reference Committee recommends this approval.

2. The "Essentials of an Approved Clinical Laboratory" were adopted by the Council in compliance with instructions received from the House of Delegates in 1923. For the more practical rating of laboratories, the Council at its February meeting adopted a statement of the "Essentials for the Listing of Physicians Specializing in Clinical Work and Pathology" and requests approval of the House of Delegates for these "Essentials" as submitted in supplement B, page 118, of the Handbook. The Reference Committee recommends this approval.

3. The "Essentials of an Approved Department of Radiology and Roentgenology" were approved by the House of Delegates in 1929. For the more satisfactory classification of such laboratories the Council in February, 1932, adopted "Essentials for Admission to List of Physicians Specializing in Radiology" and requests approval for these "Essentials" as submitted in supplement C, page 121, of the Handbook. The Reference Committee recommends this approval.

4. The following resolution, introduced by Dr. G. Henry Mundt, delegate from Illinois, was considered by the Reference Committee:

*Resolved,* That it is the opinion of the House of Delegates of the American Medical Association that physicians on the staffs of hospitals approved for intern training by the Council on Medical Education and Hospitals should be limited to members in good standing of the American Medical Association, this ruling to apply to all hospitals except federal, state, county and municipal institutions.

The Reference Committee regards this resolution as an expression of opinion in favor of a standard which should be striven for, and as such approves it, recognizing at the same time that it may not be desirable at present to make it a hard and fast rule.

5. The Reference Committee has considered the resolution introduced by Dr. C. B. Wright, delegate from Minnesota, pertaining to the Surgeon General's Library at Washington, and recommends the adoption of the resolution.

Irvin Abell, Chairman.
William Allen Pusey.
F. S. Crockett.
Seale Harris.
J. F. Burnham.

The first section of the report was adopted on motion of Dr. Abell, seconded by Dr. H. B. Everett, Tennessee, and carried.

Dr. Abell moved that the second section of the report dealing with essentials of an approved clinical laboratory, be adopted. The motion was seconded by Dr. Frederic E. Sondern, New York, and carried.

On motion of Dr. Abell, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the third section of the report, referring to essentials of an approved department of radiology and roentgenology, was adopted.

Dr. Abell moved that the fourth section of the report dealing with the resolution introduced by Dr. G. Henry Mundt, Illinois, be adopted. The motion was seconded by Dr. E. P. Sloan, Illinois, and carried.

On motion of Dr. Abell, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the fifth section of the report with reference to the resolution pertaining to the Surgeon General's Library was adopted.

Dr. Abell moved that the report be adopted as a whole. The motion was seconded by Dr. Mather Pfeiffenberger, Illinois, and carried.

It was moved by Dr. Abell that the motion of the House adopted a year ago, with reference to the location of the Surgeon General's Library, be rescinded. The motion was seconded by Dr. Albert E. Bulson, Indiana, and carried unanimously.

### Report of Reference Committee on Reports of Officers

The Vice Speaker, Dr. Albert E. Bulson, took the chair.

Dr. C. E. Mongan, Chairman, presented the following report:

#### ADDRESS OF SPEAKER

1. The speaker has called attention to the tremendous responsibility resting on the House of Delegates of molding and guiding public opinion and formulating the fundamental principles that will bring about acceptable readjustments wherein all the traditions and achievements of the medical profession will be conserved and its relationship to the patient and public enhanced. We heartily approve of that recommendation and in furtherance further recommend that the Delegates of the House of Delegates of the American Medical Association tender to their state societies at the annual meeting a full report of the transactions of the House of Delegates of the American Medical Association.

2. The Speaker stressed the point that all persons presenting resolutions to the House of Delegates should appear before the Reference Committees considering the resolution introduced and give reasons for its adoption, so that the Reference Committee should have full information concerning the offering of the resolution; and, further, those members who are opposed to resolutions offered in the House of Delegates should also appear and give argument sustaining their objections. Unless this procedure is followed, a Reference Committee cannot render to the House of Delegates an intelligent and comprehensive opinion.

3. In order that the Tuesday afternoon executive session shall not aimlessly concern itself with irrelevant matters, your Speaker recommends that you authorize your Secretary, Chairman of the Board of Trustees and Speaker to formulate a program of pending questions that the year's activities and experience indicate as meriting executive consideration. We recommend the adoption of that portion of the Speaker's address.

#### ADDRESS OF PRESIDENT

4. In the portion of the President's address which relates to the study of economics, he says: "It seems to me that a new committee might be formed, or that some member of a permanent staff might be delegated to cooperate with the Bureau and Councils for the purpose of further study of some of the plans in European countries and any new plan suggested. I am not at all sure how much change, if any, should be in our present plan, but I do think that if there were a committee working on these problems for possibly the next five years, it might be able to suggest some changes that would help solve problems in this country."

Your committee suggests that the study of medical economics deserves careful consideration and has already been studied by the Bureau of Economics and by the Committee on the Costs of Medical Care.

If it seems desirable that a permanent committee be appointed to study these problems in European countries and in our own country, as suggested by the President, we recommend that this committee be appointed by the Board of Trustees and that the committee cooperate with the Bureau of Medical Economics in the study of these problems.

5. We have given consideration to that portion of the President's address in which he says "There has been a tendency in some specialties and in certain communities to turn over certain cases to nurses, midwives or technicians. So far as I can see, there is no way to make the conscientious practice of medicine an easy task. And, furthermore, it has been asserted repeatedly that there are too many physicians. Although I do not believe that there are too many physicians, nevertheless, I do think that in order to give the people the best care, the actual practice of medicine must be kept in the hands of physicians."

We heartily endorse that statement in the President's address on the principle that all medical work be done by medical men.

6. We especially call attention of every member of the House of Delegates to the President's comment on "graduate training." This part of his address is too long to incorporate in the report, but it should be the conscientious duty of every member of the House of Delegates to read, consider and assimilate the good that is contained in these paragraphs. We heartily recommend the President's opinion on graduate training.

Concerning the President's comment on "specialization," we suggest the importance of the study of the question of proper classification and regulation of specialists. Last year, the House of Delegates requested the Council on Medical Education and Hospitals to investigate the subject of specialization, and we are awaiting their report on this subject.

#### ADDRESS OF PRESIDENT-ELECT

7. With reference to the President-Elect's comment on the development of a nation-wide scheme of postgraduate medical instruction by the Council on Medical Education and Hospitals, we realize the importance of postgraduate medical instruction and recommend that the Council on Medical Education and Hospitals of the American Medical Association promote this work by urging the state medical societies to conduct regional clinical meetings, and that the Council endeavor to provide, as far as possible, suitable information regarding material for such instruction.

8. In regard to the President-Elect's comment on a new building for the Association, we understand that the careful consideration of the erection of a new building is in the hands of the Board of Trustees and we may well await the result of their deliberation.

C. E. MONGAN, Chairman.
W. R. STEINER.
W. A. COOK.
J. F. SMITH, Secretary.

Dr. Mongan moved that the first section of the report, urging the delegates to render a full report of the transactions of the House to their respective state associations, be adopted. The motion was seconded by Dr. Joseph F. Smith, Wisconsin, and carried.

On motion of Dr. Mongan, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, the second section of the report, urging persons who present resolutions in the House to appear before the reference committees to which the resolutions are referred, was adopted.

It was moved by Dr. Mongan, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, that the third section of the report, referring to the executive session, be adopted.

Dr. Mongan recommended that the fourth section of the report be referred to the Board of Trustees, as it might entail the expenditure of money. Without further action the Vice Speaker referred this section of the report to the Board of Trustees.

The fifth section, endorsing the statement of the President that all medical work be done by medical men, was adopted on motion of Dr. Mongan, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

Dr. Mongan moved that the sixth section of the report, dealing with graduate training, be adopted. The motion was seconded by Dr. E. P. Sloan, Illinois, and carried.

Dr. Mongan moved that the seventh section of the report, dealing with postgraduate medical instruction, be adopted. The motion was seconded by Dr. Mather Pfeiffenberger, Illinois, and carried.

Dr. Mongan moved that the eighth section of the report, with reference to a new building, be adopted. The motion was seconded by Dr. Joseph F. Smith, Wisconsin, and carried.

Dr. Mongan moved the adoption of the report as a whole, excepting the portion that was referred to the Board of Trustees. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

## *Executive Session—Tuesday Afternoon, May 10*

The Speaker resumed the chair and on motion of Dr. Mather Pfeiffenberger, Illinois, seconded by Dr. H. B. Everett, Tennessee, and carried, the House went into executive session at 1:50.

### Report of the Special Committee on Legislative Activities

Dr. C. B. Wright, Chairman, presented the following report:

I. Pursuant to the action of the House of Delegates in Philadelphia in 1931, the Board of Trustees, on the recommendation of the Committee on Legislative Activities and the General Manager, Dr. West, appointed an Auxiliary Committee on Veterans' Legislation to act with the Committee on Legislative Activities. This committee consists of the following members:

Dr. Otho A. Fiedler, Sheyboygan, Wis.
Dr. Angus McLean, Detroit.
Dr. H. H. Shoulders, Nashville, Tenn.
Dr. E. A. Meyerding, St. Paul.
Dr. F. S. Crockett, La Fayette, Ind.
Dr. Holman Taylor, Fort Worth, Texas.

A combined meeting was held on Sept. 4, 1931. At this meeting the following were present:

Chairman, C. B. Wright.
Dr. J. H. J. Upham.
Dr. D. Chester Brown.
Dr. E. H. Cary.
Dr. Angus McLean.
Dr. H. H. Shoulders.
Dr. E. A. Meyerding.
Dr. F. S. Crockett.
Dr. Otho A. Fiedler.
Dr. Olin West.
Dr. Morris Fishbein.
Dr. William C. Woodward.

Methods of carrying out the instructions of the House of Delegates were discussed and the resolution submitted to the House of Delegates by Dr. H. H. Shoulders was carefully considered.

Following this meeting, Dr. Barrett, a former commander of the Wisconsin State Legion, attended the National Convention of the American Legion in Detroit. At Minneapolis Dr. E. A. Meyerding and the chairman arranged a meeting with Mr. E. V. Cliff, Minnesota member of the National Executive Committee of the American Legion. At this meeting the suggestion was made that a committee from the American Legion and one from the American Medical Association talk over the situation.

#### SECRETARIES' CONFERENCE

At the annual conference of state secretaries and editors of state journals in November, 1931, these committees had a second meeting. Following this meeting Dr. Barrett (through the influence of Dr. Fiedler) attended the meeting of the Executive Committee of the American Legion, then in session in Indianapolis.

Immediately following the secretaries' conference, Dr. West was informed by telephone that representatives of the American Legion would be glad to meet with the representatives of the American Medical Association in Indianapolis.

#### INDIANAPOLIS CONFERENCE

The Indianapolis conference was held on Nov. 19, 1931. Those attending were:

Representing the American Legion: Mr. Watson B. Miller, chairman of the Rehabilitation Committee of the Legion; Mr. John A. Hartman, National Liaison Officer; Mr. E. V. Cliff, and Mr. E. A. Hayes, members of the Executive Committee of the Legion, and Dr. Edward W. Thompson, president of the Indiana Hospital Association.

Representing the American Hospital Association: Mr. Paul H. Fesler, president.

Representing the American Medical Association: Dr. Olin West, Dr. H. H. Shoulders, Dr. F. S. Crockett, Dr. Otho A. Fiedler, Dr. E. A. Meyerding and Dr. C. B. Wright.

The Shoulders resolution was fully discussed and points of view on veterans' care were fully presented by the various groups. The result of this conference was a better understanding and a desire on the part of every one to continue the discussion. This resulted in the Chicago conference.

#### CHICAGO CONFERENCE

The Chicago conference was held at the headquarters of the American Medical Association on Dec. 30, 1931. There were in attendance, in addition to our committee, members of the Board of Trustees, Dr. Olin West, Dr. Morris Fishbein and Dr. William C. Woodward of the American Medical Association; Mr. E. A. Hayes, Mr. E. V. Cliff and Capt. Watson B. Miller, representing the American Legion; Mr. Paul H. Fesler (president) and Dr. Bert W. Caldwell (executive secretary) of the American Hospital Association; Dr. Martin Cooley, representing the United States Veterans' Administration; and a number of others from the various organizations who were interested in this subject.

This was a round table discussion of all aspects of veterans' care, and the representative of the Veterans' Administration spent a great deal of time discussing the subject from their standpoint. Again the Shoulders plan was very thoroughly presented.

A tentative basis of agreement was suggested by Dr. E. H. Cary and passed, as follows: (1) That the hospital building program should stop, except for the erection of hospitals for the care of patients suffering from nervous and mental diseases and tuberculosis, and all building plans should be modified as far as possible to meet the future needs of the civilian population by location and distribution; (2) that a modification of veterans' legislation should be asked, allowing that veterans be taken care of in the nonfederal hospitals at home and that all acute medical surgical conditions should be so cared for. All in attendance were urged to consider carefully this tentative agreement and as far as possible obtain reactions from their own organizations.

Mr. Miller then proposed that the representatives of the American Medical Association, American Hospital Association, Committee on Rehabilitation, Veterans' Administration and American Legion confer in Washington at a date to be determined later. This proposal was accepted.

#### WASHINGTON CONFERENCE

Sunday evening, Jan. 31, 1932, we had a preliminary meeting with the representatives of the American Hospital Association at the Mayflower Hotel in Washington.

On the morning of Feb. 1, 1932, we met with the Rehabilitation Committee of the American Legion. About 120 representatives of the Legion from all parts of the country were present. Dr. Shoulders explained his plan to this group and Mr. Fesler presented the resolution passed by the American Hospital Association in Toronto, urging the use of nonfederal hospitals for the care of veterans.

The same afternoon we attended a conference in the board rooms of the Veterans' Administration under the chairmanship of Dr. C. M. Griffith, medical director of the Veterans' Administration.

The representatives of the various groups present were:

Medical Advisory Council of the Veterans' Administration:

Dr. L. F. Barker, Baltimore.
Dr. Kennon Dunham, Cincinnati.
Col. W. F. Lorenz, Madison, Wis.
Dr. L. I. Dublin, New York.
Major Gen. R. U. Patterson, Surgeon General of the Army.

American Hospital Association:

Col. F. A. Washburn, Superintendent, Massachusetts General Hospital.
Dr. S. S. Goldwater, New York.
Dr. N. W. Faxon, Rochester, N. Y.
Dr. N. R. Kneifl, St. Louis, Catholic Hospital Association.
Mr. Paul H. Fesler, Minneapolis, president of the American Hospital Association.

American Legion:

Mr. E. A. Hayes, Illinois.
Mr. E. V. Cliff, Ortonville, Minn.
Capt. Watson B. Miller, Washington, D. C.
Dr. William M. Leffingwell, New York, represented by Dr. H. D. Shapiro, Washington, D. C.

American Medical Association:

Dr. E. H. Cary.
Dr. D. Chester Brown.
Dr. E. B. Heckel.
Dr. Thomas S. Cullen.
Dr. Olin West.
Dr. William C. Woodward.
Dr. Angus McLean.
Dr. Holman Taylor.
Dr. Otho A. Fiedler.
Dr. F. S. Crockett.
Dr. H. H. Shoulders.
Dr. E. A. Meyerding.
Dr. C. B. Wright.

At this conference the duties of the Medical Advisory Council were explained by Dr. Barker as simply advisory, not on policies but on individual problems which came up for solution. The Council has no initiative, no power, and no spontaneous action is taken, except in answer to definite requests for advice regarding specific problems. Dr. Barker stated that, so far as he knew, the Medical Council had never recommended the providing of beds in veterans' hospitals.

Dr. Dublin then explained that on request he had outlined a tentative plan along actuarial lines as to the number of beds necessary to carry out fully the provisions of the law if all the disabled veterans were to be taken care of. He stated that 129,000 beds would be necessary, but they never had recommended providing these beds and in fact their estimates were made for the purpose of showing how expensive the carrying out of this plan would be.

Dr. West spoke from the standpoint of the American Medical Association, urging the stopping of building of federal hospitals and the use of nonfederal hospitals of the country for the care of veterans. He felt that the government should take care of the veteran disabled because of service-connected injuries or illnesses, of nervous and mental and of tuberculous cases, and possibly of some other chronic cases. He also expressed the opinion that Mr. Cliff's idea of getting service in local institutions for emergency cases might be adopted, but he urged that the man whose disability has no service connection and who is able to take care of himself should do so and be made to do so and the government should not pauperize its citizens by giving to those who are able to provide for themselves.

The representatives of the American Legion expressed their opposition to the insurance plan of Dr. Shoulders. They stated that this plan had been fully presented and discussed by them and that rather than discuss concrete plans it would be better to try to arrive at some agreement on policies.

After discussions by Mr. Fesler, Dr. Goldwater, Mr. Cliff, Mr. Miller and Mr. Hayes, Dr. Cary suggested the formation of a smaller committee to formulate some policy that we could all agree on for future action and which would act as a liaison committee with the Veterans' Administration. This was agreed upon and the following committee was appointed:

Committee of the American Legion:

Mr. E. V. Cliff.
Mr. E. A. Hayes.
Dr. William M. Leffingwell (represented by Dr. Shapiro).
Capt. W. B. Miller.

Committee of the American Medical Association (appointed by the representatives of the Board of Trustees present):

Dr. E. H. Cary.
Dr. C. B. Wright.
Dr. William C. Woodward.
Dr. Holman Taylor.

Committee of the American Hospital Association:

Mr. Paul Fesler.
Dr. N. W. Faxon.
Dr. Hugh Scott.
Dr. F. A. Washburn.
Dr. N. R. Kneifl (*Catholic Hospital Association*).

The general meeting was then adjourned and the smaller committee went into session and elected Mr. Paul H. Fesler chairman. After a great deal of discussion, this committee reached a tentative agreement subject to endorsement by the various organizations.

This tentative agreement is the final result of the various meetings held. The principles laid down can be used as the foundation for future cooperation. While it does not represent the principles of the Shoulders resolution as to insurance, it does give an opportunity to work out constructive legislation. Many of the medical profession, who are not committee members, feel very much pleased with results so far and express the opinion that we have accomplished more in this short time than could have been expected. Dr. Shoulders is entitled to a great deal of credit for having brought his resolution before the House of Delegates. It offered a distinctly constructive proposal that has served to make possible conferences and discussions of a most helpful nature and has centered attention of all groups concerned on the undesirable features of the method now in use under government control.

We therefore wish you would give this tentative agreement which follows your careful consideration:

1. There are no available statistics on which a comparison could be made between the cost of care in federal and nonfederal hospitals, for the same class of cases. It was agreed that the chairman, Mr. Fesler, should obtain a study of treatment costs in federal and nonfederal hospitals, comparing the cost of care of like diseases.

2. At the request of the Legion a definition of an emergency was agreed on which was as follows: "An emergency case, in the opinion of this committee, is a case where there is need for medical or hospital service which cannot be furnished by veterans' hospitals promptly enough to prevent avoidable danger to the health and life of the patient or to prevent a lasting disabling condition." This is more of a legal than a medical definition—it covers a great deal.

3. It was recommended that the hospital program of the American Legion having to do with nervous and mental and tuberculous cases and service-connected cases be approved, including the extension of hospitals for the care of these cases where necessary, it being definitely understood, however, that the beds provided by the extension of hospitals for nervous and mental and tuberculous cases will not be used for the care of general medical and surgical non-service-connected cases. It was further agreed that there were non-service-connected general medical and surgical conditions of a chronic nature that the nonfederal hospital would not care to accept, and conversely there would be service-connected cases which might be more satisfactorily cared for in nonfederal hospitals.

4. On the motion of Dr. Cary, the chairman was authorized to appoint a committee to draw up an amendment to the existing law to permit veterans to be taken care of in home hospitals by their own doctors at government expense. On this committee are Dr. Woodward, Mr. Cliff and Dr. Faxon.

5. It was recommended that liaison committees be organized in every state, consisting of representatives of the State Hospital Association, the State Medical Association and the State Legion and the local regional representatives of the Veterans' Administration, looking toward better cooperation among these groups.

6. Mr. Hayes, representing the American Legion, urged the continued advice and cooperation of the members of the medical and hospital associations as the "best and most skilful care available was necessary in the treatment of disabled veterans."

The committee then adjourned, agreeing to meet at the call of the chairman. It was further agreed that a report should be made which could be sent to all the groups at the conference.

While in Washington, at the request of Representative McClintic, members of our committee presented arguments for the care of veterans with acute medical and surgical conditions in local hospitals by local physicians.

### DISCUSSION

An attempt to evaluate the concrete results of our year's work is difficult. We believe, however, that we have accomplished something. The result of educational work of all kinds is often intangible but, if properly done, in the long run is often more fruitful than concrete results without a secure foundation. As this work has progressed throughout the country, numerous plans have been suggested. A number of Legion posts have adopted the Shoulders insurance plan, a number have adopted the emergency care plan, and various other plans have been suggested or adopted throughout the country. When one realizes that there are approximately 10,000 Legion posts, the impossibility of reaching a majority of them before the Legion convention in September with our machinery is quite apparent. Regardless of concrete plans, however, we have been able to bring to the attention of an interested, and the most influential, group in this country the benefits of individualistic practice and the danger of any type of federal or state medicine for the general medical and surgical care of the veterans and the general population, and particularly the danger to the veteran suffering from acute medical or surgical conditions. This also holds true in the early diagnosis of cancer, tuberculosis, diabetes, nephritis and other diseases.

We believe that the work we have started should continue. On every side the medical profession is being confronted with health activities which, started with the highest motives in most instances, have through publicity and propaganda diverted the attention of the public from the practicing physician as the most essential factor in any public or private health program. The most essential factor in the proper care of the veteran is that he be taken care of by a doctor who is a well informed, interested practitioner of medicine in the local community, who is unfettered by official "red tape."

### SUMMARY

First, our committee has established, through the Board of Trustees, a standing committee cooperating with the American Legion, the American Hospital Association and the Veterans' Administration to work out some change in policy in regard to the care of veterans.

Second, we have stimulated the medical legionnaires and the profession throughout the country to interest the local Legion posts in the dangers of federalized medicine from the standpoint of the veteran and the country.

Third, members of our committee have discussed veterans' legislation before the secretaries' conference and before the Annual Congress on Medical Education, Medical Licensure, and Hospitals.

Fourth, we have written and stimulated editorials and articles in the state medical journals on veterans' legislation. In this work Dr. Shoulders has been particularly active.

Fifth, every member of the committee has talked before groups of medical men and legionnaires, not only in their own but also in other states.

Sixth, by stimulating the establishment of a permanent committee in all states, representing the American Legion, American Hospital Association, Veterans' Administration and the American Medical Association, the machinery is gradually being built up for better mutual understanding and to prepare the way for any change in policy which may come in the future.

### II. HEARING ON RURAL INFANCY AND MATERNITY BILL

An additional matter of interest was the hearing on the Maternal and Infancy bill before the Committee on Commerce in the United States Senate on Feb. 4, 1932. Dr. Holman Taylor of Texas, Dr. H. M. Johnson (sent by the Minnesota State Medical Association), Dr. George W. Kosmak of New York, Dr. W. D. Chapman of Illinois, Dr. W. C. Woodward and Dr. C. B. Wright spoke against this bill.

We would urge the members of the House of Delegates to write to their senators for the report of the hearing on S. F. 572. Apparently there is a great need for information regarding this proposed legislation on the part of many members of our association, and we feel the members of the House of Delegates should be informed on this subject. There is a strong sentimental appeal in all legislation which purports to be for the benefit of mothers and children.

This bill differed from the old Sheppard-Towner bill in that it applied only to the rural population and to towns under 50,000. The reason for this limitation of course was not apparently well founded because statistical analyses, as brought out at the hearing, fairly uniformly showed that maternal and infancy death rates are less in rural than in urban districts.

It was also shown that as far as could be determined the operation of the Sheppard-Towner Act had no influence on maternity and infancy death rates.

This bill was referred out from the Committee on Commerce of the Senate with the rural aspects of the bill stricken out. There was also a minority report against this bill signed by Senators George H. Moses, Edwin S. Broussard, Hubert D. Stephens, Harry B. Hayes, Josiah W. Bailey, Marcus A. Coolidge and Hiram Bingham.

We would also recommend your reading, if you have not done so, Senator Bingham's careful analysis of how the money was actually spent which was appropriated under the Sheppard-Towner Act. We would also like to call attention to the careful analysis of the subject "Federal Subsidies for Rural Maternal and Infant Hygiene," by Dr. Woodward. This can be obtained from the office of the American Medical Association.

It might be worth while for the officers of the American Medical Association to arrange a conference between the Committee on Legislative Activities of the American Medical Association and representatives of the organization of state health officers to find out why the health officers so persistently lobby for federal instead of state control of health activities.

C. B. WRIGHT, Chairman.
E. H. CARY.
J. H. J. UPHAM.
THOMAS S. CULLEN.
D. CHESTER BROWN.
COMMITTEE ON LEGISLATIVE ACTIVITIES.

III. After careful consideration the committee agrees to the purpose and purport of the resolutions, introduced by Dr. Shoulders and referred to the Reference Committee on Legislation and Public Relations and then to the Committee on Legislative Activities and to its Auxiliary Committee on Veterans' Legislation, and recommends that the House of Delegates refer these resolutions back to the Committee on Legislative Activities without instructions.

C. B. WRIGHT, Chairman.
D. CHESTER BROWN.
E. H. CARY.
H. H. SHOULDERS.
E. A. MEYERDING.
F. S. CROCKETT.
HOLMAN TAYLOR.
THOMAS S. CULLEN.
WILLIAM C. WOODWARD, Ex Officio.

Dr. Wright moved that section I of the report dealing with veterans' legislation be adopted and that the committee be continued. The motion was seconded by Dr. B. F. Bailey, Nebraska, and carried, after discussion by Dr. Junius B. Harris, California.

It was moved by Dr. Wright that section II of the report, referring to the hearing on the rural infancy and maternity bill, be adopted. The motion was seconded by Dr. Mather Pfeiffenberger, Illinois, and carried.

Dr. Wright moved that section III of the report, referring to the resolutions introduced by Dr. H. H. Shoulders, Tennessee, be adopted. The motion was seconded by Dr. H. H. Shoulders, Tennessee, and carried.

On motion, duly seconded and carried, the report was adopted as a whole.

## Resolution on the Appointment of a Committee to Study Birth Control

Dr. J. D. Brook, Michigan, moved the adoption of resolutions providing for the appointment by the President of a suitable Committee on the Study of Birth Control.

The motion was seconded by Dr. Carl F. Moll, Michigan, and discussed by Dr. Charles E. Mongan, Massachusetts, and Dr. J. W. Van Derslice, Illinois.

### REPORT OF REFERENCE COMMITTEE ON EXECUTIVE SESSION

Dr. Samuel P. Mengel, Pennsylvania, for the Reference Committee on Executive Session, presented the following report:

This is a controversial subject and the committee believes that it would not be advisable at this time to inject this subject before the profession. The committee therefore disapproves the adoption of the resolutions.

J. W. VAN DERSLICE, Chairman.
S. P. MENGEL.
ARTHUR W. BOOTH.
J. F. D. COOK.

Dr. J. W. Van Derslice, Illinois, moved, as a substitute for Dr. Brook's motion, that the recommendation of the Reference Committee on Executive Session be adopted. The motion was seconded by Dr. John F. Hagerty, New Jersey, and carried, after discussion by Dr. Holman Taylor, Texas.

## Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. W. F. Braasch, Chairman, presented the report of the Reference Committee dealing with the Report of the Board of Trustees.

Dr. J. H. J. Upham, a Trustee, read a statement from the Board of Trustees in reply to questions raised in the report of the Reference Committee.

The subjects in the report of the Reference Committee were discussed by Dr. W. F. Braasch, Minnesota; Dr. Junius B. Harris, California; Dr. J. W. Van Derslice, Illinois; Dr. Olin West, Secretary; Dr. C. B. Wright, Minnesota; Dr. William Duffield, California; Dr. Wendell C. Phillips, a Past President; Dr. H. H. Shoulders, Tennessee; Dr. B. F. Bailey, Nebraska; Dr. Isaac A. Abt, Section on Pediatrics; Dr. Holman Taylor, Texas; Dr. G. Henry Mundt, Illinois; Dr. J. W. Burns, Texas; Dr. H. M. Johnson, Minnesota, and Dr. A. E. Bulson, Indiana.

On motions duly seconded and carried, the following report of the Reference Committee on Reports of Board of Trustees and Secretary was adopted section by section and as a whole:

Your committee notes with commendation the evidence of progress made during the past year as shown by the reports submitted to the Board of Trustees by the various bureaus and committees. Unless the members of the House of Delegates have taken the time to review carefully each item of the report, they cannot conceive of the volume and variety of progressive work carried on under their supervision. It is a great pity that such information cannot be disseminated among the entire membership of the Association. If it were possible, every Fellow would appreciate how much is being accomplished by his financial support, which amounts individually to so modest a sum. The action taken by the trustees in maintaining the present Fellowship dues receives our whole-hearted approval. This is no time to diminish the Association activities, which a reduction in income would necessitate. Rather than diminish our activities, we should increase them. The ever increasing problems confronting organized medicine as the result of the present social and economic upheaval demand vigorous consideration and early solution if possible, at our hands.

### THE JOURNAL

Your committee sets its stamp of approval on its official publication; namely, The Journal of the American Medical Association. We are glad to know that it is generally regarded as a recognized leader in its field by both medical and lay critics. The Journal offers every one of us the opportunity to keep in touch with the developments of modern medicine. Every member of the Association should regard it his duty to read its contents carefully. Your committee is glad to know of the continued support accorded the special journals published by the Association, which are maintaining the high standard set by the organization. The Association is to be complimented on the high character of its publication.

### HYGEIA

Your committee desires to commend the continuous progress made by Hygeia in the development of its circulation and the increased interest among physicians as well as the laity. The fact that, in spite of the present financial conditions, the management is able not alone to pay operating costs but to make a modest net income, merits hearty approval. We particularly approve of the improvements made by its editorial department, embracing the cover, the type, and the general make-up. We note with satisfaction the character of the articles and the adaptation of features employed with success by other magazines. Hygeia is deserving of support by the medical profession. The least that could be done is to see that it is in every public library in the country.

### QUARTERLY CUMULATIVE INDEX MEDICUS

Your committee notes with interest the fact that this is the first year that the Association has become solely responsible for the financial support of the Quarterly Cumulative Index Medicus. Although it will be a source of additional expense, we believe that continuation of this important publication is essential to scientific medicine and, in assuming this responsibility, the Association is conveying a great benefaction to the future of scientific medicine.

### LIBRARY

Your committee would especially recommend the continued development of the package library service, which has been increased during the year some 20 per cent. The importance of this work is difficult to appreciate in that it makes available a wide range of material ordinarily unobtainable in outlying districts. This, together with the correspondence regarding medical references, is a most important service of the Association.

### COUNCIL ON PHARMACY AND CHEMISTRY

We note that the work of the Council on Pharmacy and Chemistry has been going on apace. No activity sponsored by the Association has done more to raise the standard of medicine than the extraordinary work carried on by the Council and its subsidiary, the Chemical Laboratory. It has been a most important factor in establishing the high standard of therapy set by our association. We would especially commend The Journal for its action in giving full publicity to the investigations of the Council. The Council has done distinct service through its publication of New and Nonofficial Remedies, the annual printing of the Council Reports, of special reports, of Useful Drugs and the Handbook for Interns, all of which are of the greatest practical importance to the profession. We would also commend the study recently carried on by the Council in the field of intravenous therapy. The wiles of advertisers have led some of the profession to believe that intravenous therapy offers special merits over other forms of medication. The Council deserves great credit for demonstrating that many of these claims were inspired by commercialism, and that intravenous therapy is indicated only in special conditions. The Council has shown quite conclusively that, for routine medication, the oral or rectal route is safer and to be preferred.

The importance of the Committee on Foods, which has recently been given an independent status, is becoming quite evident. While it may be too early to pass judgment as to the final value of its work, nevertheless it would seem that what it has already accomplished is of a distinctly constructive nature. If it can influence and correct any untruthful statements made in the advertising of foods, it will be of great value to the public. If it can be of help in giving the profession a better idea of the value of certain nutritional products, it will also be worth while.

### BUREAU OF HEALTH AND PUBLIC INSTRUCTION

The important work done by the Bureau of Health and Public Instruction merits commendation. Efforts to stimulate the interest of the laity in medical problems should be furthered in every legitimate way. The influence of the radio seems to be increasing apace. We who are forced to listen to the so-called health messages given out by charlatan advertisers naturally resent their blatant audacity. We urge the continuance of the efforts that have been made to stop this obnoxious publicity.

Your committee commends the efforts made to stimulate interest in periodic health examinations. In this connection it should be emphasized that the examination given must be thorough and include all the modern clinical methods. Without complete physical and laboratory data, periodic health examinations will fail of future approval.

We commend the close cooperation established with lay organizations, such as the Parents and Teachers Congress. Every effort should be made to have the medical profession take the lead in all matters pertaining to health.

### BUREAU OF LEGAL MEDICINE AND LEGISLATION

The work of the Bureau of Legal Medicine and Legislation has been of value to the medical profession in keeping the Association and its members informed in regard to the ever increasing legislative problems, both state and national, which affect the practice of medicine. The staff of this bureau has been of great aid in the past year in giving freely of legal advice and in helping to solve the various legislative problems that have arisen.

### INCOME AND EXPENDITURE

Although many rightful demands are undoubtedly made on the Board of Trustees for increased funds by the various bureaus and committees, nevertheless your committee believes that some of the activities which the Association is now carrying on are inadequately financed. We refer particularly to the work carried on by the Committee on Legislation and by the Bureau of Medical Economics.

### BUREAU OF MEDICAL ECONOMICS

The significance of the work carried on by the Bureau of Medical Economics in its bearing on the future of organized medicine cannot be overestimated. Taking advantage of its accumulating data, and guided by the experience of the medical profession in other countries, the solution of economic problems in the future should be made more easy. The need of such a movement has long been widely recognized and sporadic attempts to cope with the various problems have been made by individual state societies during the past decade. It may be remembered that the demand for the institution of this all important bureau was made in the House of Delegates last year by the delegates from California and passed with much enthusiasm. The pity is that such a movement was not started years ago, so that the data which might have been accumulated could now be available when sorely needed. Now that the machinery has been tardily erected for this all important work, it would seem that everything possible should be done to quicken its aims. Its director undoubtedly deserves credit for what he has already accomplished and for the wide scope outlined for the future activities of his department. It appears to your committee, however, that the need for immediate results in obtaining all possible data, the desirability of making them available to every state association, and the furtherance of their adoption, is imperative.

While the wide range of topics for investigation noted in his report is to be commended, it is evident that if all the subjects were properly investigated, years of work with the present personnel would be necessary in order to arrive at any conclusions. In the solution of the many problems involved, not alone is it essential to have an accumulation of facts bearing on the problems, but principles for their solution must be recommended. The question might well be raised whether it would not be advisable to single out a few of the most urgent problems and pursue them to an immediate constructive conclusion. The difficulties of solving the problems peculiar to various districts of the country again call our attention to the desirability of regional supervision.

In reviewing the financial budget of the Board of Trustees, we note that the sum made available for carrying on the operations of this bureau was inadequate. Your committee recommends that this amount should be greatly increased and that the scope and the personnel of this department be augmented.

### HOUSE OF DELEGATES

Your committee desires to call attention to the fact that resolutions and instructions adopted by the House of Delegates are occasionally overlooked by the Board of Trustees or other officers of the Association and fail to receive any executive action. Doubtless, in some cases, logic and common sense would explain such action. To be specific, we refer to a recommendation made by the President of the Association and adopted last year by the Reference Committee on Reports of Officers and approved by the House of Delegates, which endorsed the arrangement of scientific meetings in various sections of the country by association officers. A word of explanation in regard to its disposition might have been included in the report of the Trustees to the House of Delegates.

In conclusion your committee would raise the question whether the members of the House of Delegates representing the membership of our Association are given sufficient opportunity to discharge their duties as such representatives and to take part in the activities of the Association. It is open to question whether they can become familiar with its policies in the short annual sessions now held. In raising the question, we do not reflect on the ability and judgment of the Board of Trustees and the officers who direct the affairs of the Association. It is possible, however, that a more permanent influence and contact with the activities by members of the House of Delegates might be of mutual benefit. This could be attained either by meeting several days prior to the week of the annual session, or by semiannual meetings of the House of Delegates instead of annual as at present. We realize that this subject has been brought up before and has met with adverse action. It is only after discussion with a number of the delegates that the desirability of further cooperation on the part of the House of Delegates is brought up for further consideration.

Your committee presents these suggestions for your consideration. It is recommended that the Delegates record their desires definitely for further guidance.

On request, the Secretary explained the methods used in trying to build up Fellowship.

## NEW BUSINESS

### Resolution on Increase of Burden of Taxation on Medical Profession

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, The relief of economic chaos is dependent on the restoration of confidence and stability of thought among the American people in the place of hysteria, confusion and indecision;

Whereas, The Congress of the United States has in contemplation a return to the income tax in effect during the World War;

Whereas, The burden of earned income tax falls heavily as class legislation on the physician and surgeon who works day and night for the small fees he may be able to collect; be it

*Resolved,* That Congress be immediately advised of the injustice, inequality and the burden of this taxation on the medical profession in this time of depression and that they be requested to ponder, stop, look and listen to our appeal against injustice to the medical profession of America.

### Resolution on Assistance to Small Hospitals in Raising Their Standards

Dr. R. W. Fouts, Nebraska, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Whereas, At the annual meeting of the American Medical Association held in Detroit in June, 1930, a resolution was unanimously passed directing the Council on Medical Education and Hospitals of the American Medical Association to begin a program of standardizing the small hospitals of the country; and

Whereas, No classification of the small hospitals has been established, and many of these small institutions would gladly welcome a survey and constructive advice relative to improving their service and adding to their efficiency; and

Whereas, The majority of the 6,612 hospitals now on the official register of the American Medical Association are small hospitals which should have created for their benefit certain definite standards which they desire to meet; and

Whereas, It is the belief of many hospital authorities that the American Medical Association, composed of practitioners of medicine and surgery in all specialties, is the one organization best able to give them constructive information relative to improving hospital service; therefore be it

*Resolved,* That this House of Delegates urge the Council on Medical Education and Hospitals to give all possible assistance to the small hospitals so that their standards may be raised and their efficiency accordingly improved.

### Memorandum Concerning Reduction in Number of Officers in the United States Army

Dr. Holman Taylor, Texas, presented the following statement, which was referred to the Reference Committee on Legislation and Public Relations:

For many years, from time to time, since the World War, there has been discussion in Congress looking to a reduction in the number of officers in the army. Whenever this has come up, even in the time of President Coolidge, it was thoroughly understood that the Medical Department of the Army was already underofficered to meet the present peace time needs of the army adequately, particularly so with respect to the officers of the Medical Corps and the Dental Corps. So it was a complete surprise when on last Friday (May 5) the Committee on Appropriations of the House recommended to Congress the passage of the proposed army appropriation bill for 1933, to see that a cut or reduction of 2,000 officers from the army was recommended, and that it would affect the Medical Department. It was always understood that any cut would not be made applicable to the Medical Department, known as the "non-promotion list," but it would come from the "promotion list," or line of the army, which in time of peace can best stand a reduction in the number of officers, if any is to be made.

It is now known that a study of that bill by the general staff indicates that the heaviest reduction of all will fall on the Medical Department. In other words, the Medical Department will stand to lose 323 officers, of which number 260 will be from the Medical Corps alone. A greater percentage loss than any other branch or service. The Medical Department has had a hard time for many years to keep up with the many demands made on it with its present strength. A further reduction at this time will literally ruin the Medical Department. It will be forced to withdraw from practically all the activities now carried on under War Department policies which are considered essential and will render the Medical Department unable to continue to operate efficiently many of its station hospitals and otherwise care for the different military posts. This will cause suffering, inefficiency and a lowering of morale. The situation is a most serious one, in which the American Medical Association is naturally interested, both from the standpoint of interest in their brothers in the Medical Corps of the Army and as patriotic citizens who naturally do not desire to see the welfare of the enlisted men of the army adversely affected. They will suffer because of lack of proper medical attention if this reduction takes place.

A statement of such interest on the part of the President of the American Medical Association, or other proper official, addressed to those in authority in Washington, would be most timely, and probably produce prompt results.

RECOMMENDATIONS

1. Send a telegram to the President in substance as follows:

"Recent newspaper articles indicate that there will be a cut of 2,000 officers from the army. Although the Medical Department is well known to be underofficered at the present time, it is understood that this reduction in officers will seriously affect the Medical Department; in fact, the largest cut will fall on that department. The American Medical Association is deeply concerned that such action is even contemplated and earnestly hopes that no action will be taken that will so reduce the personnel of the Medical Department of the Army that its efficiency may thereby be impaired.

2. Similar telegrams to be sent to the speaker of the House of Representatives and to the Secretary of War.

### Request for Discussion of Restriction of Prescriptions of Medicinal Alcohol

Dr. J. W. Van Derslice, Chairman of the Reference Committee on Executive Session, presented the following message, which the Reference Committee had not received through the usual channels, and with which it felt it had nothing whatever to do:

A member of the New York delegation requests that the Committee on Executive Session provide, in their order of business, time for the general discussion of the present status of legislation in regard to restriction of prescriptions of medicinal alcohol.

The Speaker referred this to the committee composed of the Chairman of the Board of Trustees, the Secretary of the Association and the Speaker of the House, which was appointed by the House to arrange a program of subjects for consideration at the executive session.

### Report of Board of Trustees

Dr. J. H. J. Upham, a Trustee, presented the following report: The Board reports that it endorses the resolutions introduced by Dr. Southgate Leigh, Virginia, relative to the need for closer cooperation between the county and state associations and the American Medical Association.

Dr. F. S. Crockett, Indiana, moved that the report be adopted. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

### Request for Publicity by Reference Committees Concerning Hearings on Matters Referred to Them

Dr. D. E. Sullivan, New Hampshire, presented the following request, which was referred to the Reference Committee on *Rules and Order of Business:*

Whenever a resolution or motion is referred to a Reference Committee it shall be the duty of the chairman of such committee to give it publicity in the Daily Bulletin and by such other means as may be convenient, stating the subject-matter and the time and place at which a hearing will be given.

### Report of Committee on Medicinal Alcohol

Dr. William H. Mayer, Chairman, presented the following statement:

A request was made that this committee report to the House of Delegates the present status of the legislation which has been the subject of so much controversial discussion before this group for some years. The committee felt some years ago that it was best that this subject be discussed in executive *session because of the tenderness of the situation.*

When the Lambert-Yellowley suit was before the Supreme Court, the House of Delegates felt that, in the event that section 7 of the Volstead Act were declared unconstitutional, the prescription of alcohol should have some adequate regulation. A committee consisting of Dr. Southgate Leigh, Dr. Paul White, Dr. Tom B. Throckmorton and myself was created to draft such regulations in the event of the success of this suit. The committee had referred to it from time to time certain other resolutions, one of which was that certain bills should be prepared against the continuance of the irrelation of the United States government limiting the practice of medicine and the principle involved in section 7 of the Volstead Act.

This committee was also required to draft, and make a part of this bill, certain reasonable regulations. We studied the proposition. We understood the practical side of it; we appealed to the various governmental officers for their suggestions, and we felt that our time would be wasted were we to present any such legislation under the conditions which then existed.

We appeared before the Wickersham Committee, feeling that this subject was germane. Dr. Woodward and myself represented the American Medical Association, and I think that I may say with pardonable pride that, of all the recommendations of the Wickersham Commission, one unanimous report was in complete support of the principle outlined by our association.

These bills were eventually drafted after the Wickersham Commission recommended that the irrelation contained in the limitation from nine to ten days be removed from the Volstead Act. These bills were prepared and introduced at the present session of Congress. There were similar bills in the House, one presented by Senator Copeland of New York and the second by Representative James Beck of Pennsylvania. Hearings were held on these bills. Dr. Woodward appeared before the House hearings, at which time Colonel Woodcock and Commissioner Doran felt that we had placed in those bills no statement concerning the amount which might be prescribed at any one time. You can readily see our difficulty. Were we to have made this amount a large quantity of alcohol, our recommendation would have been the subject of considerable criticism; secondly, had we put a small quantity in, say four ounces of prescription, immediately we would have been accused of trying to increase the service charge to our patients by repeated subscriptions. Being between Scylla and Charybdis, we simply stated that we felt that that should be subject to adequate regulation. Commissioner Doran and Colonel Woodcock asked that the bill be so amended that it would contain definite legal restrictions to the point that it would place in the hands of the Secretary of the Treasury and the Attorney-General, now jointly controlling the medicinal alcohol situation, the power to put down those regulations governing the prescription of whisky.

Now, gentlemen, I want to say that I don't know what the medical association would do without Dr. Woodward at Washington. His contacts and his associations, the high plane on which you are represented, is something that you could not buy elsewhere. His commissionership of health in the District of Columbia for over twenty years has given him an entrée and a standing there which makes him respected by all people, and you gentlemen derive reflected credit from his career. So our motives were always understood in these things; but we have first fought for a principle, that principle which reserves the right to you to prescribe in the legitimate practice of medicine anything that God has created or may create, for the benefit of your patient. Aside from that I think that we have also represented your point of view in that we have insisted that regulatory measures should always be in force so that the intent and purpose of the laws of these United States might be safeguarded.

We have no other statement to make concerning this. I don't care whether they put all the whisky six miles under the ocean so far as I am concerned, but I do say if this principle were extended it might be just as easy for Congress to say that you must consult with a recognized chiropractor before you do an appendectomy.

I have made some thirty-six trips to Washington, back and forth, during the last six years. I may say that the representatives of the departments of the government are most cordial gentlemen. Our bills at the present time have been postponed in one committee, mainly because one of our state association groups did not play ball. They simply went to one legislator and he had letters from the doctors that this was not necessary, so why bother with it, and for that reason his adverse vote resulted in the postponement of this thing at least temporarily. It may not be carried out this session, but the favorable report of the committee I think will eventually be gotten and that this thing will eventually become a law.

Until the Wickersham Commission made its report, the President had really no obligation not to veto this bill. At the present time I think he has. You know he is on record as saying that modification means nullification, so therefore if he sticks to that principle he must veto this legislation if it is passed by both Houses of Congress.

What I would like to have from you gentlemen is your expression of confidence in your Board of Trustees and its committee appointed for this purpose. Six years of work in this has been a distinct pleasure. Gentlemen, that is the situation. I hope you understand it and that this House will either express its confidence in its committee and the Board of Trustees in this matter, or see fit to advise us as to a course which will be acceptable to you.

Some organizations throughout the country have gone in the wrong direction and have taken unto themselves to dictate policies which have become confused with ours. In one particular case an estimable gentleman stepped into the committee and gave, I think, the most remarkable lecture on the medicinal values of beer that I have ever heard, so much so that I was convinced when he got through that I thought it was wonderful, and yet I recognized that the people there did not understand, that it was clouding the issue on a principle and helped to defeat our purposes at the time. For that reason I wish your committee might have your complete confidence in this matter so that we might go forward in the future.

Dr. Samuel J. Kopetzky, New York, moved that the report be adopted and that it is the sense of the House that it express its thanks, its appreciation, and its confidence in the committee which has just reported, the motion was seconded by Dr. Carl F. Moll, Michigan, and carried after discussion by Dr. Southgate Leigh, Virginia.

### Time of Thursday Meeting

Dr. Arthur C. Morgan, Pennsylvania, moved that the Thursday afternoon meeting be called to order at 1 o'clock. The motion was seconded by Dr. Samuel J. Kopetzky, New York, and carried.

Dr. B. F. Bailey, Nebraska, moved that the House arise from executive session. The motion was seconded by Dr. Samuel J. Kopetzky, New York, and carried.

The House recessed at 5:10 p. m., to meet at 1 o'clock, Thursday afternoon, May 12.

## *Fourth Meeting—Thursday Afternoon, May 12*

The House of Delegates was called to order at 1 p. m., by the Speaker, Dr. F. C. Warnshuis.

### Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, stated that Dr. L. C. Ingram, who had been vouched for by Dr. G. H. Edwards, president of the Florida Medical Association, and by the other delegate from Florida, Dr. Bundy Allen, but whose name did not appear on the Secretary's list of delegates, had made application to be seated in place of Dr. C. D. Christ. Dr. Brook moved that Dr. Ingram be seated. The motion was seconded by several delegates, and carried, and Dr. L. C. Ingram was seated.

Dr. Brook stated that a total of 157 delegates had filed proper credentials, and moved that the report of the Reference Committee be adopted. The motion was seconded by Dr. Charles J. Whalen, Illinois, and carried.

On motion of Dr. Mather Pfeiffenberger, Illinois, seconded by Dr. Arthur J. Bedell, New York, and carried, the House dispensed with the reading of the minutes.

### Report of Reference Committee on Rules and Order of Business

Dr. R. W. Fouts, Nebraska, presented the following report:

The following resolution was introduced by Dr. D. E. Sullivan of New Hampshire:

> *Resolved*, That whenever a resolution is referred to a reference committee it shall be the duty of the chairman of such committee to give publicity to the same in the Daily Bulletin and by such other means as may be convenient, stating the subject matter, the time and place at which a hearing will be given.

Your committee feels that it would be impractical to establish a hard and fast rule, such as implied in this resolution, but would suggest that any one interested in a resolution referred to a reference committee immediately communicate with the chairman of said committee as to the time and place of their meeting.

B. L. Bryant, Chairman.
R. W. Fouts, Secretary.

On motion of Dr. Fouts, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the report of the Reference Committee on Rules and Order of Business was adopted.

### Report of Reference Committee on Legislation and Public Relations

Dr. Grant C. Madill, Chairman, presented the following report:

1. Your committee has considered the statement presented by Dr. Holman Taylor, objecting to the reduction of officers in the Medical and Dental Corps of the Army, and approves of the recommendations contained therein.

2. Your committee also approves of the resolutions introduced by Dr. Burt R. Shurly, relative to increasing the burden of taxation on the medical profession.

Grant C. Madill, Chairman.
J. F. Hagerty.
Southgate Leigh.
C. J. Whalen.
A. A. Ross.

It was moved by Dr. Madill that the first section of the report, protesting against the reduction of medical officers in the army, be adopted. The motion was seconded by Dr. Alexius McGlannan, Maryland, and carried.

Dr. Madill also moved that the second section of the report, dealing with the burden of taxation on the medical profession, be adopted. The motion was seconded by Dr. Samuel P. Mengel, Pennsylvania, and carried.

On motion of Dr. Madill, seconded by Dr. Alexius McGlannan, Maryland, and carried, the report of the Reference Committee on Legislation and Public Relations was adopted as a whole.

The House recessed for ten minutes.

### Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. N. B. Van Etten, Chairman, read the following report:

Considering the request of the Secretary for a decision of the House of Delegates on the question of either amending the By-Laws or adding a standing rule, incorporating the sense of the resolution adopted at the Philadelphia session in 1931, which reads as follows:

> *Resolved,* That it is the sense of the House of Delegates of the American Medical Association that these provisions of the Constitution and By-Laws of the American Medical Association dealing with the credentials of constituent state associations shall be so construed by the Reference Committee on Credentials that when a constituent state association reports that one of its delegates and his respective alternate are both unable to attend a specified annual session of the American Medical Association in which one of them could have functioned as a delegate, under such conditions (provided the constituted body or council of such a constituent state association is authorized by its state constitution and by-laws to act for the state association and its house of delegates), when such authorized state body has duly elected others of its members to fill the vacancies caused by the absence of both a delegate and his respective alternate, such a duly elected substitute delegate, or his duly elected substitute alternate who presents proper credentials shall be eligible to regular membership in the House of Delegates of the American Medical Association for such a specified annual session.

Your Reference Committee on Amendments to Constitution and By-Laws believes that a standing rule may wisely be added to the section on rules for the guidance of the Committee on Credentials which shall be 5 and shall read as follows:

> When a constituent state association reports that one of its elected delegates and his elected alternate are both unable to attend a specified annual session of the American Medical Association, the constituted authority of said constituent state association may fill the vacancies caused by the absence of both an elected delegate and his elected alternate, and such a substitute delegate or his substitute alternate who presents proper credentials signed by the president and secretary of said constituent state association shall be eligible to regular membership in the House of Delegates of the American Medical Association in such a specified session.

N. B. Van Etten, Chairman.
Walter F. Donaldson.
John H. O'Shea.
H. M. Johnson.

It was moved by Dr. Van Etten, seconded by Dr. Frederic E. Sondern, New York, and carried after discussion by Dr. Holman Taylor, Texas, that the report be adopted.

Dr. Van Etten moved that the Standing Rules be amended by the addition of this rule as number 5 under the heading Rules for the Guidance of the Committee on Credentials. The motion was seconded by Dr. Grant C. Madill, New York, and carried.

### Report of Reference Committee on Medical Education

Dr. Irvin Abell, Chairman, presented the following report:

Your Reference Committee has considered the resolution introduced by Dr. R. W. Fouts urging the Council on Medical Education and Hospitals to give all possible assistance to the small hospitals so that their standards may be raised and their efficiency be accordingly improved, and recommends its adoption.

Irvin Abell, Chairman.
William Allen Pusey.
J. F. Burnham.
Seale Harris.
F. S. Crockett.

On motion of Dr. Abell, seconded by Dr. Mather Pfeiffenberger, Illinois, and carried, the report of the Reference Committee on Medical Education was adopted.

### Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following supplementary report of the Judicial Council, which was adopted on motion of Dr. Follansbee, seconded by Dr. G. Henry Mundt, Illinois, and carried:

The privilege of healing the sick as a profession is a right granted only to those properly qualified and licensed by the state. It is a privilege belonging only to the medical profession. It is a sacrifice of professional dignity that this exclusive right of medicine is so often sold for individual gain or its possessor deprived of it against his will. In increasing numbers, physicians are disposing of their professional attainments to lay organizations under terms which permit a direct profit from the fees or salaries paid for their services to accrue to the lay bodies employing them. Such a procedure is absolutely destructive of that personal responsibility and relationship which is essential to the best interests of the patient.

Outstanding examples of this type of unearned gain are not difficult to find. There are insurance companies administering workmen's compensation benefits wherein the salaries or fees paid to the physician by the insurance company are so much below the legal fees on which the premium paid by the industry is based as to furnish a large direct profit to the insurance company. As mentioned in a former report of the Council, certain hospitals are forbidding their staffs of physicians to charge fees for their professional services to "house cases" but are themselves collecting such fees and absorbing them in the hospital income. Some universities, by employing full time hospital staffs and opening their doors to the general public, charging such fees for the professional care of the patients as to net the university no small profit, are in direct and unethical competition with the profession at large and their own graduates. They are making a direct profit by a practice of questionable legality, from the professional care. There are other examples which could be cited but those mentioned suffice.

The increasing number of such instances indicates either a thoughtlessness or a selfishness on the part of the participants that is disturbing to the Judicial Council and in its opinion warrants the Council in bringing the practice, with the disapproval, again to the attention of the House of Delegates and through it to the profession at large.

## NEW BUSINESS

### Proposed Amendment to Constitution

Dr. Southgate Leigh, Virginia, requested that section 2, article 5, of the Constitution be amended so that the presidents of the state societies shall be ex officio members of the House of Delegates.

The Speaker announced that this proposed amendment would lie over until the next annual session.

### Resolutions of Appreciation to Dr. Edward B. Heckel

Dr. C. W. Roberts, Georgia, presented the following resolutions, which were adopted on motion of Dr. Roberts, seconded by Dr. Frederic E. Sondern, New York, and carried unanimously by a rising vote:

> Whereas, Dr. Edward B. Heckel has served this House of Delegates for a quarter of a century; and
>
> Whereas, He has served continuously as a member of the Board of Trustees for eight years, during seven of which he has been unanimously chosen by the Board as its Chairman, in recognition of the faithfulness, self-sacrifice and efficiency that he has displayed; be it
>
> *Resolved,* That the House of Delegates extend to Dr. Heckel a rising vote of thanks; and be it further
>
> *Resolved,* That this resolution be spread on the minutes of the House of Delegates and that a copy of it be suitably engraved and presented to Dr. Heckel.

### Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, stated that Dr. G. F. Zinninger, Ohio, who presented no credentials but whose name appeared on the Secretary's list and who was vouched for by other delegates from Ohio, desired to be seated as alternate delegate for Dr. C. W. Waggoner, Ohio.

Dr. J. Newton Hunsberger, Pennsylvania, moved that Dr. Zinninger be seated. The motion was seconded by Dr. John P. De Witt, Ohio, and carried.

It was announced that there were now 158 delegates who had filed proper credentials. The Secretary called the roll and stated that more than a quorum was in attendance.

### Report of Reference Committee on Hygiene and Public Health

Dr. Junius B. Harris, Chairman, stated that the Reference Committee had considered "A Standard Classified Nomenclature of Disease" as submitted by the National Conference on Nomenclature of Disease in a temporary draft, and recommended that, until the conference had completed its report, the Reference Committee would have no report to make except that, on completion of the draft by the conference, the matter in toto should be submitted to the International Bureau of Vital Statistics and then to the American Medical Association. Dr. Harris moved that the report be adopted.

Dr. Frederic E. Sondern, New York, moved as a substitute for Dr. Harris's motion that the House favor the endorsement of the preliminary draft of "A Standard Classified Nomenclature of Disease." This motion was seconded by Dr. Arthur J. Bedell, New York, and carried, after discussion by Dr. Junius B. Harris, California, and Holman Taylor, Texas.

## ELECTION OF OFFICERS

### Election of President-Elect

The Speaker called for nominations for the office of President-Elect of the American Medical Association.

Dr. Randolph Winslow, Maryland, nominated Dr. Dean Lewis, Baltimore. The nomination was seconded by Dr. Irvin Abell, Kentucky; Dr. Mather Pfeiffenberger and Dr. G. Henry Mundt, Illinois; Dr. E. G. Wood, Tennessee; Dr. Walter Ralph Steiner, Connecticut; Dr. J. F. Hassig, Kansas; Dr. Walter F. Donaldson, Pennsylvania; Dr. John H. O'Shea, Washington; Dr. A. W. Skelsey, North Dakota, and Dr. Alexius McGlannan, Maryland.

Dr. Southgate Leigh, Virginia, nominated Dr. Hugh S. Cumming, Washington, D. C. The nomination was seconded by Dr. Edmond F. Cody, Massachusetts; Dr. Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health; Dr. Bertram L. Bryant, Maine; Dr. Carl F. Moll, Michigan; Dr. J. N. Baker, Alabama, and Dr. H. W. Wade, Philippine Islands.

Dr. Fred Moore, Iowa, nominated Dr. Walter L. Bierring, Des Moines, Iowa. The nomination was seconded by Dr. William Duffield in behalf of the full California delegation.

The Speaker declared the nominations closed, and appointed as tellers Dr. Samuel J. Kopetzky, New York; Dr. William R. Molony, California; Dr. T. O. Freeman, Illinois; Dr. S. L. Baysinger, Missouri, and Dr. E. G. Wood, Tennessee.

The Secretary announced that 152 members of the House had recorded themselves as present, and that 151 votes had been cast, of which Dr. Dean Lewis, Baltimore received 73; Dr. Hugh Cumming, Washington, D. C., 47, and Dr. Walter L. Bierring, Des Moines, Iowa, 31. The Speaker declared that none of the candidates had received a majority vote of the House.

The Secretary announced as the result of the second ballot that there were 153 members of the House who had recorded themselves as present and that 152 votes had been cast, of which Dr. Dean Lewis, Baltimore, received 98 and Dr. Hugh Cumming, Washington, D. C., 54.

The Speaker declared Dr. Dean Lewis, having received the majority of the votes cast, elected President-Elect of the American Medical Association.

On motion of Dr. Southgate Leigh, Virginia, duly seconded and carried, the election of Dr. Dean Lewis was made unanimous.

### Election of Vice President

Dr. H. A. Miller, New Mexico, nominated Dr. W. H. Seemann, New Orleans. Dr. John H. O'Shea, Washington, seconded the nomination and moved that the nominations be closed and the Secretary cast the unanimous ballot of the House for Dr. Seemann.

The Speaker declared that as Dr. Seemann was a member of the House of Delegates, he was not eligible to election as Vice President.

Dr. Louis J. Hirschman, Michigan, nominated Dr. Rudolph Matas, New Orleans, as Vice President. The nomination was seconded by Dr. Seale Harris, Alabama, who moved that the nominations be closed and the Secretary be instructed to cast the unanimous ballot of the House for Dr. Matas as Vice President. The motion was regularly seconded and carried, and the Secretary cast the unanimous vote of the House of Delegates for Dr. Rudolph Matas. The Speaker declared Dr. Matas elected as Vice President of the American Medical Association for the ensuing year.

### Election of Secretary

Dr. A. E. Bulson, Indiana, nominated Dr. Olin West, Chicago, as Secretary, and the nomination was seconded by Dr. H. H. Shoulders, Tennessee.

Dr. Samuel P. Mengel, Pennsylvania, moved that the nominations be closed and the unanimous ballot of the House be cast for Dr. Olin West as Secretary. The motion was seconded by Dr. H. B. Everett, Tennessee, and carried unanimously.

The Vice Speaker cast the ballot of the House for Dr. Olin West, Chicago, as Secretary, and the Speaker declared Dr. West elected unanimously for the ensuing year.

### Election of Treasurer

Dr. Edward B. Heckel, Chairman, Board of Trustees, nominated Dr. Austin A. Hayden, Chicago, to succeed himself as Treasurer.

Dr. Arthur J. Bedell, New York, moved that the nomination be confirmed. The motion was seconded by several delegates, and carried, and the Speaker declared the nomination confirmed and Dr. Austin A. Hayden, Chicago, elected to the office of Treasurer.

### Election of Speaker of the House of Delegates

The Vice Speaker, Dr. A. E. Bulson, took the chair and announced that nominations were in order for Speaker of the House of Delegates.

Dr. Louis J. Hirschman, Michigan, nominated Dr. F. C. Warnshuis, Grand Rapids, Mich., as Speaker of the House of Delegates. Dr. T. O. Freeman, Illinois, seconded the nomination and moved that nominations be closed and the Secretary cast the unanimous ballot of this House for Dr. Warnshuis as Speaker. The motion was seconded by several delegates, and carried unanimously.

The Secretary cast the vote of the House and Dr. F. C. Warnshuis, Grand Rapids, Mich., was declared Speaker of the House of Delegates for the ensuing year.

### Election of Vice Speaker of the House of Delegates

The Speaker resumed the chair and called for nominations for Vice Speaker of the House of Delegates.

Dr. R. L. Sensenich, Indiana, nominated Dr. Albert E. Bulson, Fort Wayne, Ind. The nomination was seconded by Dr. John A. Card, New York; Dr. William G. Ricker, Vermont; Dr. Walter F. Donaldson, Pennsylvania; Dr. R. W. Fouts, Nebraska, and Dr. W. Albert Cook, Oklahoma, who moved that the nominations be closed and the Secretary cast the ballot for Dr. Bulson as Vice Speaker. The motion was seconded by Dr. Samuel J. Kopetzky, New York, and carried.

The Secretary cast the unanimous ballot of the House of Delegates for Dr. A. E. Bulson, Fort Wayne, Ind., for Vice Speaker of the House of Delegates and the Speaker declared Dr. Bulson elected as Vice Speaker of the House for the ensuing year.

### Election of Trustees

The Speaker announced that the next order of business was the election of a Trustee for a term of five years to succeed Dr. Edward B. Heckel, whose term of office had expired and who because of constitutional provisions was not eligible for reelection.

Dr. N. B. Van Etten, New York, nominated Dr. Arthur W. Booth, Elmira, N. Y. The nomination was seconded by Dr. Daniel S. Dougherty, New York; Dr. Samuel P. Mengel, Pennsylvania; Dr. R. H. Walker, West Virginia; Dr. R. L. Sensenich, Indiana; Dr. H. G. Stetson, Massachusetts; Dr. B. S. Pollak, New Jersey, and Dr. H. B. Everett, Tennessee, who moved that the nominations be closed and the Secretary cast the unanimous ballot of the House for Dr. Booth as Trustee of the Association. The motion was seconded by several members, and unanimously carried.

The secretary cast the unanimous vote of the House of Delegates for Dr. Arthur W. Booth, Elmira, N. Y., to succeed Dr. E. B. Heckel as a member of the Board of Trustees and the Speaker declared Dr. Booth elected as a Trustee of the Association for a term of five years.

The Speaker called for nominations for the office of Trustee to succeed Dr. Rock Sleyster, Wauwatosa, Wis., whose term of office had expired.

Dr. Joseph F. Smith, Wisconsin, placed in nomination Dr. Rock Sleyster, Wauwatosa, Wis., to succeed himself as Trustee of the American Medical Association, for a term of five years. The nomination was seconded by Dr. C. B. Wright, Minnesota; Dr. Walter F. Donaldson, Pennsylvania; Dr. J. W. Van Derslice, Illinois; Dr. William R. Molony, California; Dr. H. M. Johnson, Minnesota; Dr. D. E. Sullivan, New Hampshire; Dr. Seale Harris, Alabama; Dr. E. A. Hines, South Carolina, and Dr. E. P. Sloan, Illinois, who moved that the nominations be closed and the Secretary be instructed to cast the ballot of the House for Dr. Sleyster. The motion was seconded by Dr. Mather Pfeiffenberger, Illinois, and carried unanimously.

The Secretary cast the unanimous ballot of the House for Dr. Rock Sleyster, to succeed himself as a member of the Board of Trustees, and the Speaker declared Dr. Sleyster elected as a member of the Board for a term of five years.

## Nominations for Standing Committees

Dr. E. H. Cary, President, presented the following nominations:

Dr. E. P. Sloan, Bloomington, Ill., to succeed Dr. Donald Macrae, Jr. (deceased), on the Judicial Council for a term of five years.

Dr. Ray Lyman Wilbur, Washington, D. C., to succeed himself as a member of the Council on Medical Education and Hospitals for a term of seven years, and Dr. F. A. Washburn, Boston, for a term of six years to succeed on that Council Dr. Dean Lewis, Baltimore, who had just been elected President-Elect.

Dr. Frank H. Lahey, Boston, to succeed himself as a member of the Council on Scientific Assembly, for a term of five years, and Dr. Irvin Abell, Louisville, Ky., to succeed himself on the Council on Scientific Assembly to fill out the term of Dr. Lewis H. McKinnie (deceased), ending in 1934.

Dr. C. E. Humiston, Illinois, moved that these nominations be confirmed by the House. The motion was seconded by Dr. G. Henry Mundt, Illinois, and carried.

## Address of President-Elect Dean Lewis

The Speaker introduced President-Elect Dean Lewis, who addressed the House as follows:

*Mr. Speaker and Members of the House of Delegates:*

It is needless for me to tell you how highly honored I am. You know every one has an ambition; it has always been my ambition to be President of the American Medical Association. The only sad thing about it is that it seems like the journey's end. I don't know how I can show my appreciation for the honor that you have conferred on me more than by filling to the best of my ability the duties of the office. I am greatly indebted to you.

## Election of Affiliate and Associate Fellows

The Secretary read the following nominations for Affiliate and Associate Fellowship:

### APPLICANTS FOR AFFILIATE FELLOWSHIP APPROVED BY COUNCIL ON SCIENTIFIC ASSEMBLY

Craig, John W., Lohrville, Iowa.
Finch, H. C., Pulaski, Iowa.
Hofstetter, George, Clinton, Iowa.
Smith, Ferdinand J., Milford, Iowa.
Smith, Frank S., Nevada, Iowa.
Bennet, Eben H., Lubec, Maine.
Cobb, Oliver, W., Easthampton, Mass.
Twombley, Edward L., Boston, Mass.
Moorhead, Martha B., Minneapolis.
Rishmiller, J. H., Minneapolis.
Warham, Thomas T., Minneapolis.
Wright, C. D'A., Minneapolis.
Sweetman, R. H., Sauk Center, Minn.
Delavan, D. Bryson, New York.
Fox, George Henry, New York.
McEncroe, John F., Schenectady, N. Y.
Hawkins, John A., Solebury, Pa.
Mahon, John B., Pittston, Pa.
Stevens, J. V., Janesville, Wis.

### APPLICANTS FOR ASSOCIATE FELLOWSHIP FROM AMERICAN MEDICAL MISSIONARIES APPROVED BY JUDICIAL COUNCIL

Baker, Donald H., Mondome, Belgian Congo.
Baugh, Harold T., Andong, Chosen.
Brinkman, Harry, Resht, Persia.
Calvert, R. N., Shanghai, China.
Carman, John S., Hanumakonda, India.
Dorman, Henry G., Beirut, Syria.
Gibbons, Howard C., Burma, India.
Harley, George W., Monrovia, Liberia, West Africa.
Harris, Edwin A., Sake, Belgian Congo.
King, Judson C., Belgian Congo.
Manley, Charles R., South India.
Rue, George Henry, Seoul, Chosen.
Stannard, Raymond E., Ningpo, China.
Tuttle, Glen Willis, Belgian Congo.
Werelius, Walter R., Manipur, Assam, India.
Westcott, George W., Belgian Congo.

### APPLICANTS FOR ASSOCIATE FELLOWSHIP NOMINATED BY THE SECTIONS INDICATED

### Laryngology, Otology and Rhinology

Boyko, G. Victor, Paterson, N. J.
Gilden, Charles T., Jr., Philadelphia.
Lieban, E. Alan, New York.

### Pathology and Physiology

Cunningham, Robert S., Nashville, Tenn.
Fulton, John F., New Haven, Conn.
Langston, W. C., Little Rock, Ark.
LeCount, E. R., Chicago.
Looney, J. M., Philadelphia.
Taylor, Walter F., Dallas, Texas.

### Nervous and Mental Diseases

Jungeblut, Claus W., New York.

### Preventive and Industrial Medicine and Public Health

Brokaw, Raymond V., New York.
Exner, Max Joseph, New York.
Luckett, George S., Stanford University, Calif.
Norton, John F., Detroit.

On motion of Dr. Arthur C. Morgan, Pennsylvania, seconded by Dr. Daniel S. Dougherty, New York, and carried, the applicants listed were elected to Affiliate or Associate Fellowship in the American Medical Association, as indicated.

## Place of the 1933 Annual Session

The Speaker announced that the next order of business was the selection of the place of the 1933 annual session and requested that the Board of Trustees present nominations:

Dr. Edward B. Heckel, Chairman, Board of Trustees, stated that the officers of the Association had investigated the facilities of the cities from which invitations for the 1933 annual session of the Association had been received and reported that the following cities, mentioned in alphabetical order, had adequate facilities to accommodate a successful meeting of the Association: Atlantic City, Cleveland and Milwaukee.

Dr. F. Gregory Connell, Wisconsin, extended an invitation from Milwaukee; Dr. Walt P. Conaway, New Jersey, an invitation from Atlantic City, and Dr. C. W. Stone, Ohio, an invitation from Cleveland.

The Secretary announced that 153 delegates were registered and that of 128 votes cast, 73 were for Milwaukee, 44 for Cleveland, and 11 for Atlantic City.

The Speaker declared Milwaukee the place for the next annual session of the American Medical Association, as it had received a majority of the votes cast.

## Unfinished Business

Dr. N. B. Van Etten, New York, moved that the House of Delegates unanimously express its appreciation by a hearty vote of thanks to the Louisiana State Medical Society, to the local medical societies, to the Woman's Auxiliary, to the city of New Orleans and to the press, for their delightful hospitality. The motion was seconded by Dr. Irvin Abell, Kentucky, and carried unanimously. The Secretary was requested to tender the appreciation of the House.

The House of Delegates adjourned sine die at 3 o'clock.

# MINUTES OF THE SECTIONS

## SECTION ON PRACTICE OF MEDICINE

### WEDNESDAY, MAY 11—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. G. Gill Richards, Salt Lake City.

Dr. Adolph S. Rumreich, Washington, D. C., read a paper on "The Typhus-Rocky Mountain Spotted Fever Group: Developments in Epidemiology and Clinical Considerations." Discussed by Drs. Victor H. Bassett, Savanah, Ga.; G. Gill Richards, Salt Lake City, and Adolph S. Rumreich, Washington, D. C.

Drs. John W. Towey, Powers, Mich., Henry C. Sweany, Chicago, and Willis H. Huron, Iron Mountain, Mich., presented a paper on "A Severe Bronchial Asthma Apparently Due to Fungus Spores Found in Maple Bark." Discussed by Drs. Francis M. Rackemann, Boston; Frank Smithies, Chicago; N. F. Thiberge, New Orleans, and John W. Towey, Powers, Mich.

Dr. Walter L. Bierring, Des Moines, Iowa, introduced the lecturer for this year, Dr. William S. Thayer, Baltimore, who read a paper on "Thoughts on Medical Education in the United States."

Dr. Augustus B. Wadsworth, Albany, N. Y., read a paper on "The Value of Serum Therapy in Pneumonia, Meningitis, Scarlet Fever and Other Streptococcus Infections." Discussed by Drs. W. G. Smillie, Boston; Harold L. Amoss, Durham, N. C.; Virgil E. Simpson, Louisville, Ky., and Augustus B. Wadsworth, Albany, N. Y.

Dr. H. Milton Conner, Rochester, Minn., read a paper on "Injection of Liver Extract in the Treatment of Pernicious Anemia." Discussed by Drs. John H. Musser, New Orleans, and H. Milton Conner, Rochester, Minn.

### THURSDAY, MAY 12—AFTERNOON

A joint meeting was held with the Section on Preventive and Industrial Medicine and Public Health.

The following papers were read as a symposium on "The Relation of Private Practice to Preventive Medicine":

Dr. Frank G. Boudreau, Geneva, Switzerland: "The Relationship of the Doctor to Society." Discussed by Dr. John L. Morse, Boston.

Dr. Roger I. Lee, Boston: "Preventive Medicine in General Medical Practice." Discussed by Dr. Stewart R. Roberts, Atlanta, Ga.

Dr. J. N. Baker, Montgomery, Ala.: "Organized Medicine and Public Health." Discussed by Dr. H. F. Vaughan, Detroit.

Dr. Morris Fishbein, Chicago: "Present-Day Trends of Private Practice in the United States." Discussed by Dr. E. Starr Judd, Rochester, Minn.

The four papers were discussed by Drs. G. Henry Mundt, Chicago, and J. Cyril Eby, Plaquemine, La.

### FRIDAY, MAY 13—AFTERNOON

The following officers were elected: chairman, Dr. Reginald Fitz, Boston; vice chairman, I. I. Lemann, New Orleans; secretary, William J. Kerr, San Francisco; delegate, James S. McLester, Birmingham, Ala.; alternate, J. E. Paullin, Jr., Atlanta, Ga. Executive Committee: Dr. Ernest E. Irons, Chicago; Dr. L. W. Gorham, Albany, N. Y.; Dr. Reginald Fitz, Boston.

Dr. Alexius M. Forster, Colorado Springs, Colo., read a paper on "Nontuberculous Respiratory Diseases." Discussed by Drs. William S. Thayer, Baltimore; Frank Smithies, Chicago, and Alexius M. Forster, Colorado Springs, Colo.

Dr. Eugene S. Kilgore, San Francisco, read a paper on "Treatment of Coronary Thrombosis." Discussed by Drs. I. I. Lemann, New Orleans; William S. Thayer, Baltimore; O. P. J. Falk, St. Louis, and Eugene S. Kilgore, San Francisco.

Dr. G. Gill Richards, Salt Lake City, read the chairman's address, entitled "The Family Doctor and the Pioneer Physician of the West."

Dr. John O. Bower, Philadelphia, read a paper on "The Mortality in Acute Appendicitis." Discussed by Drs. Donald Guthrie, Sayre, Pa.; William E. Robertson, Philadelphia, and John O. Bower, Philadelphia.

Drs. Willard O. Thompson, Chicago, and James H. Means, Boston, presented a paper entitled "A Comparison of Exophthalmic Goiter in Boston and Chicago with Special Reference to the Iodine Reaction." Discussed by Drs. Frank H. Lahey, Boston; Jacob Lerman, Boston; Harry B. Friedgood, Ann Arbor, Mich.; Eugene S. Kilgore, San Francisco, and Willard O. Thompson, Chicago.

Dr. John B. Youmans, Nashville, Tenn., read a paper on "Endemic Nutritional Edema." Discussed by Drs. Roy H. Turner, New Orleans, and John B. Youmans, Nashville, Tenn.

## SECTION ON SURGERY, GENERAL AND ABDOMINAL

### WEDNESDAY, MAY 11—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Hubert A. Royster, Raleigh, N. C.

Drs. Eslie Asbury and H. Kennon Dunham, Cincinnati, presented a paper on "Thoracoplasty in Pulmonary Tuberculosis." Discussed by Drs. Alton Ochsner, New Orleans; E. J. O'Brien, Detroit; Frank K. Boland, Atlanta, Ga.; A. M. Forster, Colorado Springs, Colo.; Horace Reed, Oklahoma City, and H. Kennon Dunham, Cincinnati.

Dr. C. R. Edwards, Baltimore, read a paper on "Acute Intestinal Obstruction Due to Mesenteric Defects Requiring Massive Resection." Discussed by Drs. Owen H. Wangensteen, Minneapolis; E. D. Martin, New Orleans; Harold M. Trusler, Indianapolis; Willard Bartlett, Jr., St. Louis, and C. R. Edwards, Baltimore.

The following papers were read as a symposium on "Traumatic and Industrial Surgery":

Dr. Lloyd Noland, Birmingham, Ala.: "Some Problems of Administration in Industrial Surgery."

Dr. Grover C. Penberthy, Detroit: "The Surgeon's Responsibility in the Readjustment of the Injured."

Dr. W. L. Estes, Jr., Bethlehem, Pa.: "After-Care of the Injured."

Dr. E. Dunbar Newell, Chattanooga, Tenn.: "An Outline of the Treatment of Fractures by the General Surgeon."

These four papers were discussed by Drs. George A. Hendon, Louisville, Ky.; Joseph F. Smith, Wausau, Wis.; Willis C. Campbell, Memphis, Tenn.; Wayland Morrison, Los Angeles; Muir Bradburn, New Orleans; John Darrington, Yazoo City, Miss.; Frank Warner, Columbus, Ohio; Robert Carothers, Cincinnati, and W. L. Estes, Jr., Bethlehem, Pa.

A moving picture on fractures was shown by Dr. Robert Carothers, Cincinnati.

### THURSDAY, MAY 12—MORNING

Dr. Frank K. Boland, Atlanta, Ga., read a paper on "Results of Treatment in Acute Appendicitis." Discussed by Drs. J. C. A. Gerster, New York; John O. Bower, Philadelphia; Southgate Leigh, Norfolk, Va.; Roland Hill, St. Louis; Harold M. Trusler, Indianapolis; Horace Reed, Oklahoma City; L. F. Barney, Kansas City, Kan., and Frank K. Boland, Atlanta, Ga.

Dr. Alfred W. Adson, Rochester, Minn., read a paper on "Thrombo-Angiitis Obliterans: Results of Sympathectomy." Discussed by Drs. Arthur W. Allen, Boston, and Alfred W. Adson, Rochester, Minn.

*Dr. Hubert A. Royster, Raleigh, N. C.*, read the chairman's address, entitled "Surgical Vision."

Dr. Frederick A. Coller, Ann Arbor, Mich., read a paper on "Dehydration Attendant on Surgical Operations." Discussed by Drs. Thomas G. Orr, Kansas City, Mo.; Isidore Cohn, New Orleans; George A. Hendon, Louisville, Ky.; J. Shelton Horsley, Richmond, Va., and Frederick A. Coller, Ann Arbor, Mich.

Dr. E. Starr Judd, Rochester, Minn., read a paper on "A Study of the Late Results of Operations for Diseases of the Biliary Tract."

Dr. J. Tate Mason, Seattle, read a paper on "The Conservative Treatment of Cholecystitis."

These two papers were discussed by Drs. R. L. Payne, Norfolk, Va.; Frank H. Lahey, Boston; Moses Behrend, Philadelphia; Willard Bartlett, Jr., St. Louis; I. S. Ravdin, Philadelphia, and J. Tate Mason, Seattle.

### Friday, May 13—Morning

The following officers were elected: chairman, Dr. F. W. Rankin, Rochester, Minn.; vice chairman, Dr. Lloyd Noland, Birmingham, Ala.; secretary, Dr. Howard M. Clute, Boston; delegate, Dr. J. Tate Mason, Seattle; alternate, Dr. Frank H. Lahey, Boston.

Dr. Géza de Takáts, Chicago, read a paper on "Surgical Attempts at Increasing Sugar Tolerance." Discussed by Drs. Joseph A. Danna, New Orleans; J. Shirley Sweeney, Dallas, Texas; Seale Harris, Birmingham, Ala., and Géza de Takáts, Chicago.

Dr. G. M. Dorrance, Philadelphia, read a paper on "Essential Factors in the Ideal Cleft Palate Operation." Discussed by Drs. Gordon B. New, Rochester, Minn.; G. V. I. Brown, Milwaukee; Vilray P. Blair, St. Louis, and G. M. Dorrance, Philadelphia.

Dr. Damon B. Pfeiffer, Philadelphia, read a paper on "Anterior Hemipylorosphincterectomy for Duodenal Ulcer and Pylorospasm." Discussed by Drs. Urban Maes, New Orleans; Norman McLeod Allen, Detroit, and Damon B. Pfeiffer, Philadelphia.

Drs. Howard C. Naffziger and Ottiwell Wood Jones, San Francisco, presented a paper on "The Operative Treatment of Progressive Exophthalmos Following Thyroidectomy."

Dr. R. S. Dinsmore, Cleveland, read a paper on "Hyperthyroidism in Children."

Dr. Howard M. Clute, Boston, read a paper on "The Results of Surgery in the Treatment of Exophthalmic Goiter."

These three papers were discussed by Drs. R. E. Semmes, Memphis, Tenn.; E. R. Arn, Dayton, Ohio; Donald Guthrie, Sayre, Pa.; R. M. Howard, Oklahoma City; Willard Bartlett, Jr., St. Louis; Frank H. Lahey, Boston; Howard C. Naffziger, San Francisco; R. S. Dinsmore, Cleveland, and Howard M. Clute, Boston.

## SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

### Wednesday, May 11—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. Fred L. Adair, Chicago.

Dr. Percy W. Toombs, Memphis, Tenn., read a paper on "Preconceptional and Prenatal Care."

Dr. Alfred C. Beck, Brooklyn, read a paper on "The Management of Normal Labor."

Dr. J. C. Litzenberg, Minneapolis, read a paper on "Preventable Invalidism Following Childbirth."

These three papers were discussed by Drs. Grandison D. Royston, St. Louis; Phil C. Schreier, Memphis, Tenn.; Marie Pichel Levinson, New York; William F. Hewitt, Chicago; F. J. Schatz, St. Cloud, Minn.; Percy W. Toombs, Memphis, Tenn.; Alfred C. Beck, Brooklyn, and J. C. Litzenberg, Minneapolis.

Dr. Everett D. Plass, Iowa City, read a paper on "The Difficulties and Dangers of Forceps Deliveries."

Dr. W. E. Studdiford, New York, read a paper on "Breech Presentations and Their Delivery."

Dr. W. R. Cooke, Galveston, Texas, read a paper on "Contraindications to Cesarean Section."

These three papers were discussed by Drs. Edward L. King, New Orleans; Edward A. Schumann, Philadelphia; Grandison D. Royston, St. Louis; P. Brooke Bland, Philadelphia; H. G. Dorman, Beirut, Syria; J. Bay Jacobs, Washington, D. C.; E. D. Plass, Iowa City; W. E. Studdiford, New York, and W. R. Cooke, Galveston, Texas.

### Thursday, May 12—Afternoon

Dr. John T. Williams, Boston, read a paper on "The Relation of Respiratory Infections to Puerperal Infection." Discussed by Drs. Phillips John Carter, New Orleans; F. J. Schatz, St. Cloud, Minn., and John T. Williams, Boston.

Dr. P. Brooke Bland, Philadelphia, read a paper on "The Prevention of Maternal Injury Incident to Pregnancy and Labor from the Standpoint of the General Practitioner." Discussed by Drs. J. L. Baer, Chicago, and P. Brooke Bland, Philadelphia.

Dr. Fred L. Adair, Chicago, read the chairman's address, entitled "The Interrelationship of Mother and Fetus."

Dr. C. B. Upshaw, Atlanta, Ga., read a paper on "The Conservative Treatment of Eclampsia."

Dr. James C. Janney and Miss Elizabeth W. Walker, Boston, presented a paper on "Kidney Function in Pregnancy."

Dr. A. W. Rowe, Boston, read a paper on "The Toxemias of Pregnancy."

These three papers were discussed by Drs. E. L. King, New Orleans; Milton Smith Lewis, Nashville, Tenn.; Phil C. Schreier, Memphis, Tenn.; E. D. Plass, Iowa City; C. B. Upshaw, Atlanta, Ga.; James C. Janney, Boston, and A. W. Rowe, Boston.

Dr. George D. Huff, San Diego, Calif., read a paper on "Technic of Spinal Anesthesia in Lower Abdominal Surgery and Obstetrics." Discussed by Drs. John S. Lundy, Rochester, Minn.; H. G. Dorman, Beirut, Syria; J. B. Stoll, Fontanelle, Iowa, and George D. Huff, San Diego, Calif.

### Friday, May 13—Afternoon

The Committee on Maternal Welfare reported activity in connection with the White House Conference on Child Health and Protection. The volume on Obstetric Education has been published, and other manuscripts are now in the hands of the publishers. The members of the committee have been active in this work. The committee recommended that it be continued and that its activities be carried out in cooperation with the other organization represented on the Joint Committee for Maternal Welfare. It further recommended that the section sanction the incorporation of the Joint Committee on Maternal Welfare without the assumption of any financial responsibility by the section. The purpose of this committee is to further maternal welfare and to improve conditions surrounding maternity through the leadership of the medical profession.

On motion by Dr. Emil Novak, Baltimore, seconded by Dr. Arthur H. Curtis, Chicago, the report was adopted.

Dr. J. C. Litzenberg, Minneapolis, described the work of the American Board of Obstetrics and Gynecology.

The following officers were elected: chairman, Dr. Barton Cooke Hirst, Philadelphia; vice chairman, Dr. Willard R. Cooke, Galveston, Texas; secretary, Dr. James R. McCord, Atlanta, Ga.; delegate, Dr. Arthur H. Curtis, Chicago; alternate, Dr. Carl Henry Davis, Milwaukee.

Dr. W. H. Buecrmann, Portland, Ore., read a paper on "Vaginal Enterocele."

Dr. James C. Masson, Rochester, Minn., read a paper on "Consideration of Prolapse, Cystocele, Rectocele and True Vaginal Hernia."

These two papers were discussed by Drs. Harold E. Simon, Birmingham, Ala., and W. H. Buecrmann, Portland, Ore.

Dr. Arthur H. Curtis, Chicago, read a paper on "Adhesions of the Anterior Surface of the Liver." Discussed by Drs. Hilliard E. Miller, New Orleans; J. P. Pratt, Detroit, and Arthur H. Curtis, Chicago.

Dr. T. E. Jones, Cleveland, read a paper on "Cancer of the Cervix: A Review of Three Hundred and Seventy-Five Cases." Discussed by Drs. W. P. Healy, New York; L. Wallace Frank, Louisville, Ky., and James E. Davis, Detroit.

Drs. Emil Novak and S. M. R. Reynolds, Baltimore, presented a paper on "The Cause of Primary Dysmenorrhea, with Especial Reference to Hormonal Factors." Discussed by Drs. C. Jeff Miller, New Orleans; J. P. Pratt, Detroit, and Emil Novak, Baltimore.

## SECTION ON OPHTHALMOLOGY

### Wednesday, May 11—Morning

At the suggestion of the chairman, Dr. Harry Friedenwald, Baltimore, and on motion of Dr. Harry S. Gradle, duly seconded and carried, a committee consisting of Drs. Edward Jackson, William H. Wilder, Hunter H. McGuire, Joseph S. Lichtenberg, Arthur J. Bedell, Harry S. Gradle, Parker Heath and Harry Friedenwald was appointed to lay a wreath on the grave of the late Dr. Marcus Feingold, in token of the respect, esteem and affection of the members of the section.

Dr. Harry Friedenwald, Baltimore, read the chairman's address, entitled "The Progress of Ophthalmology."

Dr. Conrad Berens, New York, read a paper on "Resection Operation for Strabismus." Discussed by Drs. Luther C. Peter, Philadelphia; W. Thornwall Davis, Washington, D. C.; Walter B. Lancaster, Boston; Otis Wolfe, Marshalltown, Iowa, and Conrad Berens, New York.

Dr. Harry S. Gradle, Chicago, read a paper on "The Reaction Time of the Normal Pupil." Discussed by Drs. Charles A. Bahn, New Orleans; Edward B. Heckel, Pittsburgh, and Harry S. Gradle, Chicago.

Dr. William C. Finnoff, Denver, read a paper on "A Syndrome in Uveal Tuberculosis." Discussed by Drs. Ralph I. Lloyd, Brooklyn; Albert E. Bulson, Fort Wayne, Ind.; H. L. Hilgartner, Austin, Texas; Arthur J. Bedell, Albany, N. Y.; Jonas Friedenwald, Baltimore; Eugene R. Lewis, Los Angeles; Harry S. Gradle, Chicago; Sanford R. Gifford, Chicago; Sylvester J. Beach, Portland, Maine; William H. Crisp, Denver; T. B. Holloway, Philadelphia, and William C. Finnoff, Denver.

Dr. Arthur J. Bedell, Albany, N. Y., read a paper on "The Significance of Choroidal Hemorrhage." Discussed by Drs. Everett L. Goar, Houston, Texas, and William H. Wilder, Chicago.

Dr. Hunter H. McGuire, Winchester, Va., read a paper on "Gyrate Atrophy of the Choroid and Retina (Fuchs)." Discussed by Dr. T. B. Holloway, Philadelphia.

### THURSDAY, MAY 12—MORNING

Dr. Herbert Moulton, Fort Smith, Ark., exhibited specimens of choroidal sarcoma, shown later on the screen in connection with his paper.

Dr. Conrad Berens, New York, exhibited an eye speculum and a hand campimeter. (Description and cuts attached.)

Dr. Edward Jackson exhibited, for Dr. James M. Shields, Denver, a series of large photographs of specimens worked out from slides from the Clinic of Professor Fuchs, some furnished by Dr. Prentiss and some from the University of Iowa, illustrating the value of the large photograph in fixing the anatomy in the mind. These pictures showed:

1. The optic nerve entrance in a case of opaque nerve fibers.
2. A section showing the angle of the anterior chamber.
3. A section showing the retina with all its layers.
4. A further enlargement of the retina showing the rods and cones and their nuclei.

Dr. Jonas Friedenwald, Baltimore, presented a new ophthalmoscope.

Dr. John Green, Jr., St. Louis, exhibited epinephrine bitartrate powder. Also the 0.06 cross-cylinder.

Dr. Sanford R. Gifford, Chicago, exhibited cross-action iris forceps.

Dr. Derrick T. Vail, Jr., Cincinnati, exhibited an ingnipuncture conjunctival retractor.

Dr. Thomas D. Allen, Chicago, exhibited a modification of the well known instrument for implanting bone spheres into the orbit and muscle cone. In this instrument the size of the wires is increased, and there is a little slot at the bottom of the plunger so a muscle hook may be introduced, pressing on the bone sphere while the instrument is removed and the sutures tied.

Drs. Lloyd Mills and George Martyn, Los Angeles, presented a paper on "Urinary Proteose in Ocular Allergy." Discussed by Drs. Richard W. Whitehead, Denver; J. W. Jervey, Greenville, S. C.; George Piness, Los Angeles; Laura Lane, Minneapolis; Eugene R. Lewis, Los Angeles; Alan C. Woods, Baltimore; George W. Jean, Santa Barbara, Calif.; Edwin N. Robertson, Concordia, Kan.; Jonas Friedenwald, Baltimore, and George Martyn, Los Angeles.

Dr. Grady E. Clay, Atlanta, Ga., read a paper on "Angioid Streaks of the 'Retina' Associated with Pseudoxanthoma Elasticum: A Report of Seven Cases." Discussed by Drs. W. E. Fry, Philadelphia; Arthur J. Bedell, Albany, N. Y.; Jack Jones, Atlanta, Ga.; D. T. Vail, Jr., Cincinnati; Walter B. Lancaster, Boston, and Grady E. Clay, Atlanta, Ga.

Dr. Sanford R. Gifford, Chicago, read a paper on "The Permeability of the Normal and Pathologic Lens System: A Preliminary Report." Discussed by Drs. D. T. Vail, Jr., Cincinnati; Jonas Friedenwald, Baltimore, and Sanford R. Gifford, Chicago.

Dr. W. L. Benedict, Rochester, Minn., read a paper on "Foreign Proteins and Gold in the Treatment of Uveitis." Discussed by Drs. George Slocum, Ann Arbor, Mich.; Alan C. Woods, Baltimore, and W. L. Benedict, Rochester, Minn.

Dr. Edward Jackson, Denver, read a paper on "Aberrations of Eye and Lenses." Discussed by Dr. Henry C. Haden, Houston, Texas.

Dr. William T. Davis, Washington, D. C., read a paper on "Metastatic Carcinoma of the Optic Disk: Report of a Case." Discussed by Drs. George F. Suker, Chicago, and W. L. Benedict, Rochester, Minn.

Drs. Herbert Moulton and E. C. Moulton, Fort Smith, Ark., presented a paper on "Sarcoma of the Choroid: History of Six Cases with Early Operation." Discussed by Drs. Mary Knight Asbury, Cincinnati; Laura Lane, Minneapolis; Edward Jackson, Denver, and E. C. Moulton, Fort Smith, Ark.

Dr. Alan C. Woods, Baltimore, read a paper on "Uveal Pigment Hypersensitivity and Therapeusis." Discussed by Drs. Parker Heath, Detroit, and Jonas Friedenwald, Baltimore.

### FRIDAY, MAY 13—MORNING

The reports of the Committee on Compensation Tables, the Committee on the Knapp Testimonial Fund and the Committee on National Museum of Ophthalmic Pathology were published in the presession volume.

The report of the Committee on Optics and Visual Physiology was presented by Dr. Edward Jackson, Chairman.

Drs. Clifford B. Walker, Los Angeles, Bernard Samuels, New York, and F. Phinizy Calhoun, Atlanta, Ga., were elected members of the Committee on Awarding the Knapp Medal.

Dr. John Green, St. Louis, presented the report of the American Board for Ophthalmic Examinations, which was accepted.

Dr. William C. Finnoff, Denver, presented the report of the Committee to Cooperate with the National Society for the Prevention of Blindness. The report was accepted and the committee continued.

The secretary stated that in the report of the Committee on Scientific Exhibit, published in the presession volume, Dr. Bahn's name which came in too late for publication, should have been included.

Dr. Walter B. Lancaster, Chairman, presented the report of the Committee to Confer with the National Conference on Nomenclature of Disease. On motion, duly seconded, the report was received and the committee continued.

Dr. William H. Crisp, Delegate, made his report, which was accepted.

Dr. T. B. Holloway presented the report of the Executive Committee. On motion of Dr. W. B. Lancaster, seconded by Dr. Edward Jackson, the report was accepted.

The following officers were elected: chairman, Dr. F. H. Verhoeff, Boston; vice chairman, Dr. Charles A. Bahn, New Orleans; secretary, Dr. Parker Heath, Detroit; to the American Board for Ophthalmic Examination, Dr. John Green, St. Louis; to the Committee on Optics and Visual Physiology, Dr. Alfred Cowan, Philadelphia; chairman of Committee to Cooperate with National Society for the Prevention of Blindness, Dr. T. B. Holloway, Philadelphia.

The Executive Committee stated that no award was being made for ophthalmic research in the American Medical Association this year.

At the suggestion of Dr. T. B. Holloway, the members of the section stood for one minute in memory of Dr. George S. Derby.

The chairman announced that Dr. W. H. Luedde, vice chairman of the section, who had been seriously ill, was recovering.

Drs. John Green, Jr., and Carl C. Beisbarth, St. Louis, presented a paper on "Inexpert Refraction." Discussed by Drs. William H. Crisp, Denver; C. W. Rutherford, Iowa City; Laura Lane, Minneapolis; E. L. Jones, Cumberland, Md.; Hans Schroeder, New Orleans; S. B. Muncaster, Washington, D. C.; Thomas D. Allen, Chicago, and John Green, Jr., St. Louis.

Dr. C. W. Rutherford, Iowa City, read a paper on "Asthenopia, a Psychoneurosis and a Medical Responsibility." Discussed by Drs. Walter B. Lancaster, Boston; Hans Schroeder, New Orleans, and C. W. Rutherford, Iowa City.

Dr. Louis Bothman, Chicago, read a paper entitled "Further Report on the Relation of the Basal Metabolic Rate to Progressive Myopia." Discussed by Drs. W. R. Buffington, New Orleans, Meyer Weiner, St. Louis; and Louis Bothman, Chicago.

Dr. Jonas Friedenwald and Eugene Chan, Baltimore, presented a paper on "The Pathogenesis of Retinitis Pigmentosa, with a Note on the Phagocytic Activity of Müller's Fibers." Discussed by Drs. F. Herbert Haessler, Milwaukee; Parker Heath, Detroit; S. B. Muncaster, Washington, D. C., and Jonas Friedenwald, Baltimore.

Dr. Vilray P. Blair, St. Louis, showed slides illustrating "Repairs and Adjustments of the Eyelids." No discussion.

## SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

### Wednesday, May 11—Afternoon

The meeting was called to order by the chairman, Dr. Gabriel Tucker, Philadelphia.

Dr. Gabriel Tucker, Philadelphia, read the chairman's address, entitled "The Infant Larynx."

The following applications for Associate Fellowship in the section were read, and as the secretary announced that the qualifications of the applicants were satisfactory, on motion, duly seconded, they were nominated for Associate Fellowship: G. Victor Boyke, D.D.S., Paterson, N. J.; Charles T. Gilden, Jr., D.D.S., Philadelphia; E. Alan Lieban, D.D.S., New York.

Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, presented a paper on "Benign Tumors of the Trachea and Bronchi, with Especial Reference to Those of Inflammatory Origin." Discussed by Drs. Joseph C. Beck, Chicago; Thomas E. Carmody, Denver; Frank W. Konzelmann, Philadelphia; Eugene R. Lewis, Los Angeles, and Chevalier Jackson, Philadelphia.

Dr. L. W. Dean, St. Louis, read a paper on "Laboratory Investigations as an Aid in Otolaryngologic Diagnosis." Discussed by Drs. Harris P. Mosher, Boston; Burt R. Shurly, Detroit; I. S. Kahn, San Antonio, Texas; George Piness, Los Angeles, and L. W. Dean, St. Louis.

Drs. Gordon B. New and Eleanor M. Fletcher, Rochester, Minn., presented a paper on "The Selection of Treatment in Carcinoma of the Larynx." Discussed by Drs. Albert C. Broders, Rochester, Minn.; William V. Mullin, Cleveland; Joseph C. Beck, Chicago, and Gordon B. New, Rochester, Minn.

Dr. John D. Kernan, New York, read a paper on "The Treatment of Carcinoma of the Bronchus with Radon Implantations and Diathermy."

Dr. M. F. Arbuckle, St. Louis, read a paper on "The Use of Radon Seeds in the Field of Otolaryngology and Endoscopy, with Case Reports."

These two papers were discussed by Drs. Henry K. Pancoast, Philadelphia; F. E. LeJeune, New Orleans; George Taquino, New Orleans; G. W. Walker, Fresno, Calif.; John D. Kernan, New York, and M. F. Arbuckle, St. Louis.

### Thursday, May 12—Afternoon

This being the first anniversary of the death of Dr. Robert C. Lynch, the section stood in silence for one minute in his memory, and the secretary announced that flowers had been sent to Mrs. Lynch.

Dr. Eugene R. Lewis, Los Angeles, read a paper on "Biochemical Aspects of Nasal Sinus Problems." Discussed by Drs. D. C. Jarvis, Barre, Vt.; Paul R. Nemours, St. Louis; James W. Jervey, Greenville, S. C., and Eugene R. Lewis, Los Angeles.

Dr. O. Jason Dixon, Kansas City, Mo., read a paper on "A Departure in the Management of Thrombophlebitis on Experimental Studies in the Dog." Discussed by Drs. George M. Coates, Philadelphia; Robert F. Ridpath, Philadelphia; Ernest M. Seydell, Wichita, Kan., and O. Jason Dixon, Kansas City, Mo.

Dr. J. A. Babbitt, Philadelphia, read a paper on "Some Studies in Middle Ear Infection." Discussed by Drs. John Raymond Hume, New Orleans; A. G. Fort, Atlanta, Ga., and J. A. Babbitt, Philadelphia.

Dr. Ralph A. Fenton, Portland, Ore., read a paper on "Local Agents Which Increase Tissue Immunity in Sinus Mucosa." Discussed by Drs. Arthur W. Proetz, St. Louis; Hugh L. McLaurin, Dallas, Texas; Robert F. Ridpath, Philadelphia, and Ralph A. Fenton, Portland, Ore.

Dr. H. Marshall Taylor, Jacksonville, Fla., read a paper on "Hygiene of Swimming." Discussed by Drs. Austin A. Hayden, Chicago; Harvey B. Searcy, Tuscaloosa, Ala.; Homer Dupuy, New Orleans; John J. Shea, Memphis, Tenn.; J. A. Babbitt, Philadelphia, and H. Marshall Taylor, Jacksonville, Fla.

### Friday, May 13—Afternoon

The following officers were elected: Chairman, Dr. Harris P. Mosher, Boston; vice chairman, Dr. J. L. Myers, Kansas City, Mo.; secretary, Dr. John J. Shea, Memphis, Tenn.; executive committee, Drs. Thomas E. Carmody, Denver; Gabriel Tucker, Philadelphia, and Harris P. Mosher, Boston; delegate, Dr. Burt R. Shurly, Detroit; alternate, Dr. John W. Carmack, Indianapolis.

Dr. Gabriel Tucker, Philadelphia, exhibited an infant bronchoscope and an infant tracheotomy tube.

Dr. J. B. Nail, Wichita Falls, Texas, exhibited an adaptation of the Davis mouth gag to the Lynch laryngeal speculum, enabling the operator to secure exposure of the larynx.

Dr. Arthur W. Proetz, chairman, presented the report of the Committee on Necrology.

Dr. Chevalier Jackson, chairman, presented the report of the Committee on Lye Legislation.

On motion of Dr. A. R. Crebbin, New Orleans, duly seconded, the report was accepted and the committee was thanked and continued.

In presenting the report of the Examining Board in Otolaryngology, Dr. Joseph C. Beck stated that since the board was formed in 1924 it had held twenty-one examinations and that the number of certified members was 1,933. Dr. Beck moved that the report be accepted and the committee continued; the motion was seconded and carried.

Dr. H. M. Taylor, chairman, presented the report of the Committee on Otorhinologic Hygiene of Swimming. On motion of Dr. Dupuy, duly seconded, the report was received and the committee was thanked and continued.

In presenting the report of the Committee to Confer with the National Inter-Society on Deafness Prevention, Dr. Austin A. Hayden, chairman, stated that largely because of the financial difficulties in which the American Federation of Organizations for the Hard of Hearing had found itself in the past year, little had been done by the committee. On motion, duly seconded, the report of progress was received and the committee was thanked and continued.

Dr. Ernest M. Seydell, Wichita, Kan., read a paper on "Disturbances of Olfaction." Discussed by Drs. Claude L. La Rue, Shreveport, La.; George B. Collier, New Orleans; William D. Gill, San Antonio, Texas, and Ernest M. Seydell, Wichita, Kan.

Dr. John W. Carmack, Indianapolis, read a paper on "After-Care of the Radical Mastoid Operation." Discussed by Drs. Joseph C. Beck, Chicago, and John W. Carmack, Indianapolis.

Dr. C. C. Cody, Houston, Texas, read a paper on "Acute Suppurative Otitis Media in Infancy and Early Childhood." Discussed by Drs. M. A. Lischkoff, Pensacola, Fla.; W. A. Wagner, New Orleans; J. W. Jervey, Greenville, S. C.; Burt R. Shurly, Detroit, and C. C. Cody, Houston, Texas.

Dr. J. L. Myers, Kansas City, Mo., read a paper on "Electrocoagulation of Tonsils." Discussed by Drs. Philip Boebinger, New Orleans; Frederick B. Balmer, Chicago; Austin A. Hayden, Chicago, and J. L. Myers, Kansas City, Mo.

Dr. Murdock S. Equen, Atlanta, Ga., read a paper entitled "A Clinical Study of Appendicitis Following Tonsillectomy." Discussed by Drs. Charles A. McWilliams, Gulfport, Miss.; S. S. Evans, Memphis, Tenn., and Murdock S. Equen, Atlanta, Ga.

## SECTION ON PEDIATRICS

### Wednesday, May 11—Morning

The meeting was called to order at 9:05 by the chairman, Dr. Jay I. Durand, Seattle.

Dr. Jay I. Durand, Seattle, read the chairman's address, entitled "Progress in the Nutrition of Infants."

Dr. George M. Retan, Syracuse, N. Y., read a paper on "Forced Spinal Drainage in Its Relation to Infections of the Central Nervous System." Discussed by Drs. H. Ward Williams, Rochester, N. Y.; B. H. Balser, Syracuse, N. Y., and George M. Retan, Syracuse, N. Y.

Drs. Béla Schick and Samuel Karelitz, New York, presented a paper on "Treatment of Alimentary Toxicosis." Discussed by Drs. Horton R. Casparis, Nashville, Tenn.; C. Ulysses Moore, Portland, Ore.; Harry Lowenburg, Philadelphia; F. J. Schatz, St. Cloud, Minn., and Béla Schick, New York.

Dr. Sidney V. Haas, New York, read a paper on "Celiac Disease: Its Specific Treatment and Cure Without Nutritional Relapse." Discussed by Drs. John Signorelli, New Orleans; John L. Morse, Boston; Charles G. Kerley, New York, and Sidney V. Haas, New York.

Dr. James W. Bruce, Louisville, Ky., read a paper on "Prognosis of Tuberculosis in Infancy."

Dr. Horton R. Casparis, Nashville, Tenn., read a paper on "The Pediatrician's Responsibility in the Tuberculosis Problem."

These two papers were discussed by Drs. O. O. Miller, Louisville, Ky.; William H. Park, New York; Béla Schick, New York; W. Ambrose McGee, Richmond, Va.; Eli Friedman, Boston; James W. Bruce, Louisville, Ky., and Horton R. Casparis, Nashville, Tenn.

### Thursday, May 12—Morning

Dr. M. G. Peterman, Milwaukee, read a paper on "Convulsions in Childhood." Discussed by Drs. Harry Lowenburg, Philadelphia, and M. G. Peterman, Milwaukee.

Drs. Louis A. Lurie and J. Victor Greenebaum, Cincinnati, presented a paper on "Pituitary Medication in the Treatment of Abnormal Mental and Physical Conditions in Childhood." Discussed by Drs. Isaac A. Abt, Chicago, and J. Victor Greenebaum, Cincinnati.

Dr. Charles G. Kerley, New York, read a paper on "Intestinal Stasis in Children." Discussed by Drs. Maud Loeber, New Orleans; Joseph S. Wall, Washington, D. C.; C. Ulysses Moore, Portland, Ore., and Charles G. Kerley, New York.

Dr. W. Lloyd Aycock, Boston, read a paper on "The Problem of the Control of Poliomyelitis." Discussed by Drs. Edward B. Shaw, San Francisco; S. D. Kramer, Boston; A. C. Silverman, Syracuse, N. Y.; Claus W. Jungeblut, New York, and W. Lloyd Aycock, Boston.

Dr. Henry F. Helmholz, Rochester, Minn., read a paper on "The Ketogenic Diet in the Treatment of Pyuria in Childhood." Discussed by Drs. Clifford G. Grulee, Chicago; Fred W. Schlutz, Chicago; Harry Lowenburg, Philadelphia; C. Ulysses Moore, Portland, Ore., and Henry F. Helmholz, Rochester, Minn.

Drs. Fred W. Schlutz and Dorothy Fetter, Chicago, presented a paper on "The Influence of Various Milk Products and Processed Milk on Gastric Motility." Discussed by Dr. L. R. De Buys, New Orleans.

### Friday, May 13—Morning

The following officers were elected: chairman, Dr. Fred W. Schlutz, Chicago; vice chairman, Dr. M. G. Peterman, Milwaukee; secretary, Dr. Alfred A. Walker, Birmingham, Ala.; delegate, Dr. Isaac A. Abt, Chicago; alternate, Dr. A. Graeme Mitchell, Cincinnati. Executive Committee, Drs. Fred W. Schlutz, Chicago; Jay I. Durand, Seattle, and Dr. C. A. Aldrich, Winnetka, Ill.; representative on Scientific Exhibit, Dr. F. Thomas Mitchell, Memphis, Tenn.

Drs. William Weston, Columbia, S. C., Henry F. Helmholz, Rochester, Minn., and John L. Morse, Boston, were appointed to represent the section at the third International Pediatric Congress, to be held in London in 1933.

The following resolution was endorsed by the section and referred to the Committee on Foods of the American Medical Association:

> At the business meeting of the Pediatrics Section of the California Medical Association held Tuesday, May 3, 1932, the following resolution was passed:
>
> "The Section on the Diseases of Children respectfully asks the council of the California Medical Association to strongly urge the Association of Certified Milk Producers to oppose the certification of soft curd milk and milk containing added vitamin and mineral content.
>
> "It is further requested that a copy of this resolution be forwarded to the secretary of the Section on Pediatrics of the American Medical Association."

Dr. Frank C. Neff, Kansas City, Mo., presented the report of the Jacobi Fund Committee.

Dr. Harold K. Faber, San Francisco, retired from the Jacobi Fund Committee, and Dr. Jay I. Durand, Seattle, automatically became a member for a four-year term.

On motion regularly made and seconded, the report of the Jacobi Fund Committee was adopted.

Dr. Isaac A. Abt, Chicago, reported that the House of Delegates passed the necessary amendment to the By-Laws so that hereafter the section will be known as the Section on Pediatrics in place of the Section on Diseases of Children.

Resolutions on the death of Dr. Stafford McLean were presented by Dr. Frank Leech, Washington, D. C., and on the death of Dr. John Brown Manning by Dr. Oscar Reiss, Los Angeles.

The following resolution, presented by Dr. Joseph A. Henske, Omaha, was adopted:

> In view of the place of pediatrics in the medical curriculum of class A medical schools and its importance in practice, the Section on Pediatrics of the American Medical Association requests that the National Board of Medical Examiners consider the inclusion of a requirement in their examinations so that pediatrics will be considered as a major subject.

The following resolution, presented by the Executive Committee, was adopted:

> *Resolved*, By the Section on Pediatrics, that the thanks of the section be extended to the local profession of New Orleans, particularly to Dr. John Signorelli and Dr. Robert A. Strong of the pediatric group.

Dr. M. Hines Roberts, Atlanta, Ga., read a paper on "Studies in Congenital Syphilis." Discussed by Drs. Hugh McCulloch, St. Louis; Joseph Yampolsky, Atlanta, Ga., and M. Hines Roberts, Atlanta, Ga.

Dr. I. Newton Kugelmass, New York, read a paper on "The Management of Hemorrhagic Problems in Infancy and Childhood." Discussed by Drs. Heyworth N. Sanford, Chicago, and I. Newton Kugelmass, New York.

Drs. William W. Anderson, Atlanta, Ga., and Robert L. Ware, Philadelphia, presented a paper on "Sickle Cell Anemia." Discussed by Drs. George S. Graham, Birmingham, Ala., and Thomas B. Cooley, Detroit.

Drs. Hugh L. Dwyer and Frank C. Neff, Kansas City, Mo., presented a paper on "Complemental Feeding in the New-Born: Its Effect on Breast Feeding." Discussed by Drs. J. H. Eugene Rosamond, Memphis, Tenn.; Robert A. Strong, New Orleans; Milton S. Lewis, Nashville, Tenn.; Béla Schick, New York; C. Ulysses Moore, Portland, Ore.; F. J. Schatz, St. Cloud, Minn., and Hugh L. Dwyer, Kansas City, Mo.

Dr. F. Thomas Mitchell and Stephen W. Coley, Memphis, Tenn., presented a paper on "A Study in the Prevention of Rickets." Discussed by Drs. Charles J. Bloom, New Orleans; William Weston, Columbia, S. C.; J. Victor Greenebaum, Cincinnati; Martha M. Eliot, New Haven, Conn., and F. Thomas Mitchell, Memphis, Tenn.

## SECTION ON PHARMACOLOGY AND THERAPEUTICS

### Wednesday, May 11—Morning

The meeting was called to order at 9:05 by the chairman, Dr. R. L. Levy, New York.

Drs. George R. Herrmann, C. T. Stone, W. W. Bondurant and E. H. Schwab, Galveston, Texas, presented a paper on "Some Studies of Diuresis in Patients with Congestive Heart Failure." Discussed by Drs. Willard O. Thompson, Chicago, and George R. Herrmann, Galveston, Texas.

Dr. Charles M. Gruber and Isaac Y. Olch, St. Louis, presented a paper on "Myocarditis in Rabbits Produced Experimentally by Drugs." Discussed by Drs. John H. Musser, New Orleans; E. S. Kilgore, San Francisco, and Charles M. Gruber, St. Louis.

Dr. John J. Sampson, San Francisco, and Evelyn M. Anderson, Montreal, presented a paper on "The Treatment of Certain Cardiac Arrhythmias with Potassium Salts." Discussed by Drs. T. R. Harrison, Nashville, Tenn.; Louis F. Bishop, New York; J. Marion Read, San Francisco; William J. Kerr, San Francisco, and John J. Sampson, San Francisco.

Dr. Charles W. Barrier, Fort Worth, Texas, read a paper on "The Effect of Digitalis in Arrhythmias Other Than Flutter and Fibrillation of the Auricles." Discussed by Drs. Wallace M. Yater, Washington, D. C.; Louis F. Bishop, Jr., New York; W. E. Garrey, Nashville, Tenn., and Charles W. Barrier, Fort Worth, Texas.

Drs. Stewart R. Roberts, Atlanta, Ga., and Shelton P. Sanford, Savannah, Ga., presented a paper on "A Clinical Sign of Right Bundle Branch Block, with Remarks on the Disturbance of the Mechanism, the Results and Treatment." Discussed by Dr. Louis F. Bishop, New York.

Dr. J. S. McLester, Birmingham, Ala., read a paper on "The Diet in Bright's Disease." Discussed by Drs. W. B. Penney, Tacoma, Wash.; W. E. Garrey, Nashville, Tenn., and J. S. McLester, Birmingham, Ala.

### Thursday, May 12—Morning

Dr. L. Minor Blackford, Atlanta, Ga., read a paper on "Bismuth and the Treatment of Cardiovascular Syphilis." Discussed by Drs. Stewart R. Roberts, Atlanta, Ga.; William H. Goeckermann, Rochester, Minn.; Louis F. Bishop, Jr., New York, and L. Minor Blackford, Atlanta, Ga.

Dr. R. L. Levy, New York, read the chairman's address, entitled "Therapeutics and Medicine."

The following papers were read as a symposium on "Anesthesia":

Dr. Frank H. Lahey, Boston: "Advances in Anesthesia from the Standpoint of the Surgeon."

Dr. V. E. Henderson, Toronto: "The Practical Aspect of the Theories of Narcosis."

Drs. M. H. Seevers and R. M. Waters, Madison, Wis.: "Respiratory and Circulatory Changes During Spinal Anesthesia."

Dr. John S. Lundy, Rochester, Minn.: "Advances in Anesthesia from the Standpoint of the Anesthetist."

These four papers were discussed by Drs. J. T. Halsey, New Orleans; E. Starr Judd, Rochester, Minn.; A. M. Caine, New Orleans; H. M. Trusler, Indianapolis; M. H. Seevers, Madison, Wis., and John S. Lundy, Rochester, Minn.

### Friday, May 13—Morning

The following officers were elected: chairman, Dr. E. M. K. Geiling, Baltimore; vice chairman, Dr. John H. Musser, New Orleans; delegate, Dr. N. M. Keith, Rochester, Minn.; alternate, Dr. Cary Eggleston, New York; secretary, Dr. C. H. Greene, Rochester, Minn.

Dr. Henry J. John, Cleveland, read a paper on "Ten Years' Study and Follow Up of Cases of Hyperthyroidism Showing Carbohydrate Metabolism Disturbances." No discussion.

Drs. Frank A. Hartman, Clayton W. Greene, Byron D. Bowen and George W. Thorn, Buffalo, presented a paper on "Further Experience with Cortin Therapy." Discussed by Drs. A. W. Rowe, Boston; C. H. Greene, Rochester, Minn.; J. T. Halsey, New Orleans, and Frank A. Hartman, Buffalo.

Drs. J. P. Sanders, Caspiana, La., and W. T. Dawson, Galveston, Texas, presented a paper on "Efficacy of Quinidine in Malaria." Discussed by Dr. W. J. Sandidge, Shreveport, La.

Drs. Paul D. Lamson, Harold W. Brown and Charlotte B. Ward, Nashville, Tenn., presented a paper on "Some Therapeutic and Practical Considerations on the Use of Anthelmintics." Discussed by Drs. W. G. Smillie, Boston, and Paul D. Lamson, Nashville, Tenn.

Drs. W. J. Merle Scott and John J. Morton, Rochester, N. Y., presented a paper on "The Principles of Treatment in the Common Arterial Diseases of the Extremities." Discussed by Drs. Rudolph Matas, New Orleans; Edgar V. Allen, Rochester, Minn.; A. W. Allen, Boston; Alfred W. Adson, Rochester, Minn., and W. J. Merle Scott, Rochester, N. Y.

## SECTION ON PATHOLOGY AND PHYSIOLOGY

### Wednesday, May 11—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. J. Harvey Black, Dallas, Texas.

On a motion, regularly made and seconded, the following were nominated for Associate Fellowship in the section, for submission to the House of Delegates:

John F. Fulton, New Haven, Conn.
W. C. Langston, University of Arkansas, Little Rock.
E. R. Le Count, University of Chicago, Chicago.
J. M. Looney, Philadelphia.
Walter F. Taylor, Baylor University, Dallas, Texas.
Robert S. Cunningham, Vanderbilt University, Nashville, Tenn.

Dr. Carroll L. Birch, Chicago, read a paper on "Hemophilia." Discussed by Drs. Frank J. Heck, Rochester, Minn.; Owen H. Wangensteen, Minneapolis; Robert Kapsinow, Lafayette, La.; J. H. Woolsey, San Francisco, and Carroll L. Birch, Chicago.

Dr. Henry N. Harkins, Chicago, read a paper on "Granulopenia and Agranulocytic Angina." Discussed by Drs. Clyde Brooks, New Orleans; Merton M. Minter, San Antonio, Texas; Oliver W. Hill, Knoxville, Tenn., and Henry N. Harkins, Chicago.

Dr. Russell L. Haden, Cleveland, read a paper on "Simple Achlorhydric Anemia." Discussed by Drs. A. C. Ivy, Chicago; H. M. Conner, Rochester, Minn., and Russell L. Haden, Cleveland.

Dr. Max Cutler, Chicago, read a paper on "Relation of 'Chronic Mastitis' to Cancer of the Breast." Discussed by Drs. Ira H. Lockwood, Kansas City, Mo.; Charles F. Geschickter, Baltimore; William H. Harris, New Orleans, and Max Cutler, Chicago.

Dr. Charles F. Geschickter, Baltimore, read a paper on "Tumors of the Kidneys." Discussed by Drs. Alvin G. Foord, Pasadena, Calif., and Charles F. Geschickter, Baltimore.

Dr. Albert C. Broders, Rochester, Minn., read a paper on "Carcinoma in Situ Contrasted with Benign Penetrating Epithelium." Discussed by Dr. Max Cutler, Chicago.

Drs. John G. Mateer and F. W. Hartman, Detroit, presented a paper on "Carcinoma of the Duodenum: Clinical and Pathologic Aspects." Discussed by Drs. George B. Eusterman, Rochester, Minn.; Alfred S. Giordano, South Bend, Ind., and John G. Mateer, Detroit.

### Thursday, May 12—Afternoon

The following papers were read as a symposium on "Poliomyelitis":

Dr. S. D. Kramer, Boston: "Immunity to Poliomyelitis: The Mechanism of Its Production in the General Population."

Dr. Harold L. Amoss, Durham, N. C.: "Etiology and Pathology."

Dr. J. E. Gordon, Detroit: "The Diagnosis of Early Poliomyelitis."

Dr. William H. Park, New York: "The Therapeutic Use of Antipoliomyelitis Serum in Preparalytic Cases of Poliomyelitis."

Dr. Arthur T. Legg, Boston: "Paralytic Treatment."

Dr. Frank W. Laidlaw, Middletown, N. Y.: "Poliomyelitis in the State of New York."

These six papers were discussed by Drs. W. Lloyd Aycock, Boston; Edward B. Shaw, San Francisco; Lewis J. Pollock, Chicago; J. P. Leake, Washington, D. C.; A. C. Silverman, Syracuse, N. Y.; S. D. Kramer, Boston; Harold L. Amoss, Durham, N. C.; J. E. Gordon, Detroit; William H. Park, New York, and Frank W. Laidlaw, Middletown, N. Y.

### Friday, May 13—Afternoon

The following officers were elected: chairman, Dr. Clyde Brooks, New Orleans; vice chairman, Dr. William Carpenter McCarty, Rochester, Minn.; secretary, Dr. J. J. Moore, Chicago;

delegate, Dr. D. J. Davis, Chicago; alternate, Dr. J. J. Moore, Chicago; Executive Committee, Drs. A. C. Ivy, Chicago; J. Harvey Black, Dallas, Texas, and Clyde Brooks, New Orleans.

Dr. J. Harvey Black, Dallas, Texas, read the chairman's address, entitled "Some Pressing Problems in Allergy."

Drs. I. S. Kahn and B. F. Stout, San Antonio, Texas, presented a paper on "Practical Value of the Cytologic Examination of the Nasal Smear in the Differential Diagnosis Between Allergy and Infection."

Drs. Ray M. Balyeat and Herbert J. Rinkel, Oklahoma City, presented a paper on "Pathology and Symptomatology of Headaches Due to Specific Sensitization."

Dr. Samuel M. Feinberg, Chicago, read a paper on "Sustained Artificial Fever in the Treatment of Intractable Asthma: Physiologic and Therapeutic Consideration."

These three papers were discussed by Drs. Milton B. Cohen, Cleveland; George Piness, Los Angeles; M. Murray Peshkin, New York; Alfred M. Goltman, Memphis, Tenn.; N. F. Thiberge, New Orleans; B. G. Efron, New Orleans; Clyde Brooks, New Orleans; I. S. Kahn, San Antonio, Texas; Ray M. Balyeat, Oklahoma City, and Samuel M. Feinberg, Chicago.

Dr. Harry J. Corper, Denver, read a paper on "Tissue Substrate Micro Culture for Tubercle Bacilli." Discussed by Drs. Joseph E. Pottenger, Monrovia, Calif., and Harry J. Corper, Denver.

Drs. William G. Exton and Anton R. Rose, Newark, N. J., presented a paper on "The Clinical Partition of Blood Protein by Scopometry." Discussed by Drs. Foster M. Johns, New Orleans, and William G. Exton, Newark, N. J.

## SECTION ON NERVOUS AND MENTAL DISEASES

### Wednesday, May 11—Morning

The meeting was called to order at 9:15 by the chairman, Dr. Franklin G. Ebaugh, Denver.

Dr. George S. Johnson, Denver, read a paper on "Forensic Psychiatry: Review of the Procedure in Colorado." Discussed by Drs. Edward Delehanty, Denver, and George S. Johnson, Denver.

Dr. Herman Chor, St. Louis, read a paper on "Nerve Degeneration in Poliomyelitis: Changes Observed in Motor Nerve Endings." Discussed by Drs. W. Lloyd Aycock, Boston; William H. Harris, New Orleans; George B. Hassin, Chicago; Walter Freeman, Washington, D. C., and Herman Chor, St. Louis.

Drs. Claus W. Jungeblut and Earl T. Engle, New York, presented a paper on "Resistance to Poliomyelitis: The Relative Importance of Physiologic and Immunologic Factors." Discussed by Drs. W. Lloyd Aycock, Boston; Foster M. Johns, New Orleans, and Claus W. Jungeblut, New York.

Dr. Theodore T. Stone, Chicago, read a paper on "The Rôle of the Anterior Roots in Visceral Sensibility." Discussed by Drs. Lewis J. Pollock, Chicago, and Francis M. Pottenger, Monrovia, Calif.

Dr. David C. Wilson, University, Va., read a paper on "Atypical Facial Neuralgias." Discussed by Drs. Edgar F. Fincher, Jr., Atlanta, Ga.; Carrol C. Turner, Memphis, Tenn., and David C. Wilson, University, Va.

Dr. Harry B. Friedgood, Ann Arbor, Mich., read a paper on "Experimental Exophthalmos and Its Relation to the Pathogenesis of Exophthalmic Goiter." Discussed by Drs. John D. Humber, San Francisco; Charles A. Bahn, New Orleans, and Harry B. Friedgood, Ann Arbor, Mich.

Dr. S. Bernard Wortis, New York, read a paper on "Experimental Epilepsy." Discussed by Drs. Henry Daspit, Jr., New Orleans; Wilmot S. Littlejohn, Birmingham, Ala.; Walter Freeman, Washington, D. C., and S. Bernard Wortis, New York.

### Thursday, May 12—Morning

Dr. Franklin G. Ebaugh, Denver, read the chairman's address, entitled "The Crisis in Psychiatric Education."

Dr. Sanger Brown II, Albany, N. Y., read a paper on "Comments on Some Current Criticisms of Psychiatry." Discussed by Drs. H. Douglas Singer, Chicago; George W. Hall, Chicago; George Stevenson, New York, and Sanger Brown II, Albany, N. Y.

Drs. Henry R. Viets and Francis T. Hunter, Boston, presented a paper on "Lymphoblastomatous Involvement of the Nervous System." Discussed by Drs. George W. Holmes, Boston; Frank J. Heck, Rochester, Minn.; George B. Hassin, Chicago, and Henry R. Viets, Boston.

Dr. George B. Hassin, Chicago, read a paper on "Amyotrophic Lateral Sclerosis Complicated by Subacute Combined Degeneration of the Cord." Discussed by Drs. Theodore T. Stone, Chicago; Walter F. Schaller, San Francisco; Walter Freeman, Washington, D. C.; Henry R. Viets, Boston, and George B. Hassin, Chicago.

Drs. R. P. Mackay and George W. Hall, Chicago, presented a paper on "Syphilitic Amyotrophy." Discussed by Drs. Henry Daspit, Jr., New Orleans; George B. Hassin, Chicago; Theodore T. Stone, Chicago, and Carroll Turner, Memphis, Tenn.

Drs. Walter F. Schaller, Archie M. Roberts and Edward F. Stadtherr, San Francisco, presented a paper on "Acute Myelitis: Syndrome of Occlusion of the Anterior Spinal Artery at the Fifth Cervical Cord Segment." Discussed by Drs. Edwin G. Zabriskie, New York; Edmund McCollam Connely, New Orleans, and Walter F. Schaller, San Francisco.

Drs. John L. Eckel, Buffalo, and N. W. Winkelman, Philadelphia, presented a paper on "Focal Lesions of the Spinal Cord Due to Vascular Disease." Discussed by Drs. Michael Osnato, New York; Irving J. Sands, Brooklyn, and John L. Eckel, Buffalo.

### Friday, May 13—Morning

The following officers were elected: chairman, Dr. George B. Hassin, Chicago; vice chairman, Dr. Titus Harris, Galveston, Texas; secretary, Dr. Henry W. Woltman, Rochester, Minn.; delegate, Dr. Tom B. Throckmorton, Des Moines, Iowa; alternate, Dr. Edward Delehanty, Denver; Executive Committe, Drs. Walter Freeman, Washington, D. C.; Frank G. Ebaugh, Denver, and George B. Hassin, Chicago.

Dr. Edward Delehanty, Denver, alternate, presented his report.

Dr. William C. Menninger, Topeka, Kan., read a paper on "Experiments with Therapeutic Aids in a Psychiatric Hospital." Discussed by Drs. F. Garm Norbury, Jacksonville, Ill.; Thomas Heldt, Detroit, and George S. Johnson, Denver.

Dr. Edgar V. Allen, Rochester, Minn., read a paper on "Raynaud's Disease." Discussed by Drs. W. J. Merle Scott, Rochester, N. Y.; William J. Kerr, San Francisco; Arthur W. Allen, Boston, and Edgar V. Allen, Rochester, Minn.

Dr. Francis C. Grant, Philadelphia, read a paper on "Mortality from Brain Abscess." Discussed by Drs. Ernest Sachs, St. Louis; R. E. Semmes, Memphis, Tenn., and Francis C. Grant, Philadelphia.

Drs. Edward L. Hunt, New York, and James R. Lisa, Brooklyn, presented a paper on "Metastatic Abscesses of the Brain of Intrapulmonary Origin." Discussed by Drs. Gilbert C. Anderson, New Orleans; Henry Daspit, Jr., New Orleans, and James Gardner, Cleveland.

Dr. Irving J. Sands, Brooklyn, read a paper on "The "Anatomic Basis of the Clinical Manifestations of Cerebral Vascular Disorders." Discussed by Drs. George B. Hassin, Chicago, and Irvin J. Sands, Brooklyn.

Dr. Michael Osnato, New York, read a paper on "Diagnostic Criteria for the Diagnosis of Brain Tumor: General Symptoms." Discussed by Drs. Henry Daspit, Jr., New Orleans; Walter J. Otis, New Orleans; H. R. Unsworth, New Orleans; Edward Delehanty, Denver; Franklin G. Ebaugh, Denver; Henry R. Viets, Boston; Ernest Sachs, St. Louis, and Michael Osnato, New York.

## SECTION ON DERMATOLOGY AND SYPHILOLOGY

### Wednesday, May 11—Morning

The meeting was called to order at 9:10 by the chairman, Dr. George M. MacKee, New York.

Dr. MacKee presented the report of the joint committee consisting of members of this section and of the American Dermatological Association concerning the creation of a board of examiners in dermatology and syphilology.

Dr. Howard Fox, New York, moved the adoption of the report. The motion was seconded by Dr. Arthur J. Markley, Denver, and unanimously carried.

As members of this examining board, Drs. Howard Morrow, San Francisco (one year), William H. Mook, St. Louis (two years), George M. MacKee, New York (three years), and C. Guy Lane, Boston (four years) were elected.

Dr. George M. MacKee, New York, read the chairman's address, entitled "Physical Therapy in Dermatology."

Dr. O. E. Denney, Carville, La., read a paper on "Leprosy: Comments on the In Vitro Behavior of Lepra and Certain Other Acid-Fast Micro-Organisms in the Presence of Leukocytes." Discussed by Drs. Charles W. Duval, New Orleans; Harold N. Cole, Cleveland; H. Windsor Wade, Culion, P. I.; Ralph Hopkins, New Orleans, and O. E. Denney, Carville, La.

Dr. H. Windsor Wade, Culion, P. I., read a paper on "Observations on Leprosy with Special Reference to Treatment, Classification and the Tuberculoid Lesion." Discussed by Drs. Ralph Hopkins, New Orleans; Howard Fox, New York; Charles W. Duval, New Orleans; O. E. Denney, Carville, La.; Elmore B. Tauber, Cincinnati; Fred D. Weidman, Philadelphia; Hamilton Montgomery, Rochester, Minn.; C. F. Lehmann, San Antonio, Texas; George M. MacKee, New York, and H. Windsor Wade, Culion, P. I.

Drs. Sidney J. Wilson and Sim H. Hulsey, Fort Worth, Texas, and Fred D. Weidman, Philadelphia, presented a paper on "Chromoblastomycosis in Texas (the Second North American Case)." Discussed by Drs. Clark W. Finnerud, Chicago; C. Guy Lane, Boston; Bedford Shelmire, Dallas, Texas, and Fred D. Weidman, Philadelphia.

Dr. Olin J. Cameron, Ann Arbor, Mich., read a paper on "Primary Actinomycosis of the Tongue." Discussed by Drs. Bedford Shelmire, Dallas, Texas; Fred D. Weidman, Philadelphia; Howard Fox, New York; O. H. Wangensteen, Minneapolis, and Olin J. Cameron, Ann Arbor, Mich.

Dr. Norman N. Epstein, San Francisco, read a paper on "Scleredema Adultorum (Buschke)." Discussed by Drs. Harold N. Cole, Cleveland; Fred D. Weidman, Philadelphia; George M. MacKee, New York, and Norman N. Epstein, San Francisco.

Dr. J. P. Thornley, New York, moved that the section express its appreciation and thanks to Dr. O. E. Denney, Carville, La., and his staff and to Dr. Ralph Hopkins, New Orleans, for their splendid arrangements for the visit to Carville on Tuesday. The motion was seconded and unanimously carried by rising vote.

### Thursday, May 12—Morning

Dr. J. P. Thornley, New York, read a paper on "Reactions and Serologic Results Following Arsphenamine or Neoarsphenamine Treatment for Syphilis." Discussed by Drs. Ralph Hopkins, New Orleans; Clyde Cummer, Cleveland; Edward White, Dallas, Texas, and J. P. Thornley, New York.

George W. Raiziss, Ph.D., and Dr. Marie Severac, Philadelphia, presented a paper on "Further Studies of Asymptomatic Syphilis and the Effect of Various Drugs on Spirochaeta Pallida in the Brain of Rabbits and Mice." Discussed by Drs. Earl D. Osborne, Buffalo; Harold N. Cole, Cleveland; Jeffrey C. Michael, Houston, Texas; J. P. Thornley, New York; Frank W. Cregor, Indianapolis, and George W. Raiziss, Philadelphia.

Drs. Harold N. Cole, Torald H. Sollmann and Nora Schreiber, Cleveland, presented a paper on "Excretion of Mercury After Calomel Inunctions, with Some Observations on the Method of Absorption of Mercury when Used by the Inunction Route." Discussed by Drs. William H. Guy, Pittsburgh; J. P. Thornley, New York; Robert C. Jamieson, Detroit, and Harold N. Cole, Cleveland.

Drs. William H. Goeckerman and Paul A. O'Leary, Rochester, Minn., presented a paper on "Erythroderma Psoriaticum." Discussed by Drs. C. F. Lehmann, San Antonio, Texas; Harold N. Cole, Cleveland; Fred D. Weidman, Philadelphia; J. R. Allison, Columbia, S. C.; Clark W. Finnerud, Chicago; William Allen Pusey, Chicago; G. E. Johnson, Ardmore, Okla.; Ralph Hopkins, New Orleans, and William H. Goeckerman, Rochester, Minn.

Drs. Earl D. Osborne and E. D. Putnam, Buffalo, presented a paper on "Industrial Dermatoses with Special Reference to Mycotic Dermatitis in Industry."

Dr. M. E. Obermayer, Chicago, read a paper on "Eczema Due to Contact with Commercial Rubber Preparations."

These two papers were discussed by Drs. C. Guy Lane, Boston; Harry E. Alderson, San Francisco; Harry R. Foerster Milwaukee; Jeffrey C. Michael, Houston, Texas; Leste Hollander, Pittsburgh; Bedford Shelmire, Dallas, Texas; N. Anderson, Los Angeles; William Allen Pusey, Chicago; Cla W. Finnerud, Chicago; Fred D. Weidman, Philadelph Harold N. Cole, Cleveland; Everett S. Lain, Oklahoma Ci Earl D. Osborne, Buffalo, and M. E. Obermayer, Chicago.

### Friday, May 13—Morning

The following officers were elected: chairman, Dr. Francis Eugene Senear, Chicago; vice chairman, Dr. Howard T. Phillips, Wheeling, W. V.; secretary, Dr. Harry R. Foerster, Milwaukee; delegate, Dr. Frank W. Cregor, Indianapolis alternate delegate, Dr. Bedford Shelmire, Dallas, Texas.

Drs. J. V. Van Cleve and Henry F. DeWolf, Clevelan presented a paper on "Lymphogranuloma Inguinale (Lymph granulomatosis Inguinalis of Nicholas and Favre)." Discuss by Drs. Fred D. Weidman, Philadelphia; Elmo D. Fren Miami, Fla.; Lester Hollander, Pittsburgh; Harold N. C Cleveland; Howard Fox, New York, and J. V. Van Cleve, Cleveland.

Dr. Henry D. Niles, New York, read a paper on "The Relation of Roentgen Therapy to Scarring in Acne Vulgaris." Discussed by Drs. Jeffrey C. Michael, Houston, Texas; Howard Fox, New York; C. F. Lehmann, San Antonio, Texas; Fred D. Weidman, Philadelphia; Clark W. Finnerud, Chicago; J. R. Allison, Columbia, S. C.; W. J. MacDonald, Boston; George M. MacKee, New York; Elmo D. French, Miami, Fla.; Earl D. Osborne, Buffalo; E. R. Seale, Houston, Texas; William A. Rosenberg, Chicago, and Henry D. Niles, New York.

Drs. Jack W. Jones, Herbert S. Alden and Everett L. Bishop, Atlanta, Ga., presented a paper on "Pseudoxanthoma Elasticum: Report of Five Cases Showing Its Association with Angioid Streaks of the Retina." Discussed by Drs. Grady E. Clay, Atlanta, Ga.; Jeffrey C. Michael, Houston, Texas; Fred D. Weidman, Philadelphia; Hamilton Montgomery, Rochester, Minn.; Laurence R. Taussig, San Francisco, and Jack W. Jones, Atlanta.

Drs. Clinton W. Lane and C. Malone Stroud, St. Louis, presented a paper on "Pyoderma Gangrenosum with Report of an Unusual Case." Discussed by Drs. William H. Goeckerman, Rochester, Minn.; William H. Guy, Pittsburgh; Jack W. Jones, Atlanta, Ga.; M. F. Engman, Jr., St. Louis, and C. Malone Stroud, St. Louis.

Dr. Ernest K. Stratton, San Francisco, read a paper on "Cutis Verticis Gyrata (of Inflammatory Origin)." Discussed by Drs. Harry R. Foerster, Milwaukee; Harry E. Alderson, San Francisco, and Ernest K. Stratton, San Francisco.

Dr. Harold N. Cole, Cleveland, moved a rising vote of thanks to Dr. Ralph Hopkins, Dr. M. T. Van Studdiford, Dr. Henry E. Menage, Dr. J. N. Roussel, Dr. R. A. Oriol, Dr. John A. Devron, and Dr. T. A. Maxwell for their hospitality and courtesy during the meeting. The motion was seconded and unanimously carried.

---

## SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

### Wednesday, May 11—Afternoon

The meeting was called to order at 2:15 by the chairman, Dr. J. E. Gordon, Detroit.

On motion of Dr. Henry F. Vaughan, Detroit, it was voted to nominate the following for Associate Fellowship: Raymond V. Brokaw, M.D., 25 West Forty-Third Street, New York; Max Joseph Exner, M.D., 110 Morningside Drive, New York; George S. Luckett, M.D., Stanford University, Calif., and John F. Norton, Ph.D., Department of Health, Detroit.

Drs. R. E. Dyer, L. F. Badger and E. T. Ceder, Washington, D. C., presented a paper on "Endemic Typhus of the United

States: History, Recent Developments, and Present Status of Our Knowledge." Discussed by Drs. Bedford Shelmire, Dallas, Texas, and H. A. Kemp, Dallas, Texas.

Drs. E. L. Bishop, Nashville, Tenn., and H. C. Stewart, Franklin, Tenn., presented a paper on "Tuberculosis in Tennessee." Discussed by Drs. Horton B. Casparis, Nashville, Tenn.; J. N. Baker, Montgomery, Ala.; Henry F. Vaughan, Detroit, and H. C. Stewart, Franklin, Tenn.

Drs. T. P. Hughes and W. A. Sawyer, New York, presented a paper on "Significance of Immunity Tests in Epidemiology, as Illustrated in Yellow Fever." Discussed by Drs. Bolivar J. Lloyd, Washington, D. C.; Claus W. Jungeblut, New York; Charles A. Mohr, Mobile, Ala., and W. A. Sawyer, New York.

Drs. Mark F. Boyd, Tallahassee, Fla., and Warren K. Stratman-Thomas, Jacksonville, Fla., presented a paper on "Acquired Immunity in Benign Tertian Malaria." Discussed by Drs. C. C. Bass, New Orleans, and Mark F. Boyd, Tallahassee, Fla.

Dr. Ralph McBurney, Tuscaloosa, Ala., read a paper on "A Study of Conditions Bearing on Intermittence in Typhoid Carriers." Discussed by Drs. Leon C. Havens, Montgomery, Ala., and Ralph McBurney, Tuscaloosa, Ala.

### Thursday, May 12—Afternoon

A joint meeting was held with the Section on Practice of Medicine. For a report of the proceedings, see the minutes of that section.

### Friday, May 13—Afternoon

The following officers were elected: chairman, Dr. J. N. Baker, Montgomery, Ala; vice chairman, Dr. William Harvey Perkins, New Orleans; secretary, Dr. W. G. Smillie, Boston; delegate, Dr. Stanley H. Osborn, Hartford, Conn.

Dr. Allan J. Hruby, Chicago, read a paper on "Collapse Therapy: Its Public Health Aspects and Potentialities." Discussed by Drs. Stanley H. Osborn, Hartford, Conn.; J. N. Baker, Montgomery, Ala., and Allan J. Hruby, Chicago.

Dr. Donald B. Armstrong, New York, read a paper on "A Study of Sickness Cost and Private Medical Practice." Discussed by Drs. George E. Follansbee, Cleveland; Stanley H. Osborn, Hartford, Conn., and Donald B. Armstrong, New York.

Drs. G. A. Wheeler and W. H. Sebrell, Washington, D. C., presented a paper on "The Control of Pellagra." No discussion.

Dr. Willard C. Stoner, Cleveland, read a paper on "The Hospital Health Service for the Student Nurse." Discussed by Dr. Basil C. MacLean, New Orleans.

Dr. Dwight O'Hara, Boston, read a paper on "The Clinical Teaching of Preventive Medicine." Discussed by Drs. William Harvey Perkins, New Orleans, and J. E. Gordon, Detroit.

## SECTION ON UROLOGY

### Wednesday, May 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. J. Dellinger Barney, Boston.

Dr. H. L. Morris, Detroit, read a paper on "Renal Backache." Discussed by Drs. R. L. Gordon, New Orleans; A. I. Folsom, Dallas, Texas; Gideon Timberlake, St. Petersburg, Fla.; J. Dellinger Barney, Boston; W. J. Wallace, Oklahoma City; M. H. Foster, Alexandria, La.; Paul R. Stalnaker, Houston, Texas; Robert Gutierrez, New York, and H. L. Morris, Detroit.

Dr. William P. Herbst, Jr., Minneapolis, read a paper on "A Pyeloscopic and Urographic Study Before and After Renal Sympathectomy."

Dr. R. E. Cumming, Detroit, read a paper on "Structural and Functional Changes in Urinary Tract Following Transverse Myelitis."

These two papers were discussed by Drs. H. W. E. Walther, New Orleans; Henry K. Sangree, Philadelphia; M. L. Boyd, Atlanta, Ga.; William P. Herbst, Jr., Minneapolis, and R. E. Cumming, Detroit.

Dr. Henry K. Sangree, Philadelphia, read a paper on "Urinary Calculi."

Dr. Hugh H. Young, Baltimore, read a paper on "Surgery in Obstructive and Calculous Disease of the Kidney."

Dr. George H. Ewell, Madison, Wis., read a paper on "Cystine Nephrolithiasis."

These three papers were discussed by Drs. Joseph Hume, New Orleans; Paul R. Stalnaker, Houston, Texas; A. H. Lippincott, Camden, N. J.; J. U. Reaves, Mobile, Ala.; H. K. Sangree, Philadelphia, and George H. Ewell, Madison, Wis.

### Thursday, May 12—Afternoon

Dr. J. Dellinger Barney, Boston, read the chairman's address, entitled "Infarcts of the Kidney."

Dr. Henry G. Bugbee, New York, read a paper on "Operative Relief of Prostatic Obstruction."

Dr. John R. Caulk, St. Louis, read a paper on "Author's Cautery Punch Operation Continues to Reduce the Necessity for Prostatectomy."

Dr. Hermon C. Bumpus, Jr., Rochester, Minn., read a paper on "Results of Prostatic Resection over Seven Year Period."

Dr. Joseph F. McCarthy, New York, read a paper on "The Prophylaxis of Prostatism."

Dr. T. M. Davis, Greenville, S. C., read a paper on "The Present Status of Prostatic Resection."

These five papers were discused by Drs. N. F. Ockerblad, Kansas City, Mo.; A. I. Folsom, Dallas, Texas; William F. Braasch, Rochester, Minn.; Hugh H. Young, Baltimore; N. G. Alcock, Iowa City; Gideon Timberlake, St. Petersburg, Fla.; O. F. Elder, Atlanta, Ga.; R. A. Hennessey, Memphis, Tenn.; B. W. Turner, Houston, Texas; George R. Livermore, Memphis, Tenn.; John R. Caulk, St. Louis; Joseph F. McCarthy, New York, and T. M. Davis, Greenville, S. C.

### Friday, May 13—Afternoon

The following officers were elected: chairman, N. G. Alcock, Iowa City; vice chairman, J. U. Reaves, Mobile, Ala.; secretary, J. H. Morrissey, New York; delegate, Dr. Arthur L. Chute, Boston; alternate, Dr. H. W. E. Walther, New Orleans.

Dr. C. E. Ervin, Danville, Pa., read a paper on "Treatment of Patients with Urinary Tract Infection."

Dr. Edwin Davis, Omaha, read a paper on "Urinary Antisepsis—A Comparison of Methenamine, Caprokol, Pyridium and Acriflavine as to Clinical Efficiency."

These two papers were discussed by Drs. A. I. Folsom, Dallas, Texas; H. W. E. Walther, New Orleans; Anson L. Clark, Rochester, Minn.; I. G. Duncan, Memphis, Tenn.; R. L. Gordon, New Orleans; M. L. Boyd, Atlanta, Ga.; J. Dellinger Barney, Boston; C. E. Ervin, Danville, Pa., and Edwin Davis, Omaha.

Dr. M. L. Boyd, Atlanta, Ga., read a paper on "Carcinoma of Bladder: Indications for Nephrostomy and Nephrectomy." Discussed by Drs. Henry K. Sangree, Philadelphia; Hermon C. Bumpus, Jr., Rochester, Minn.; George R. Livermore, Memphis, Tenn., and M. L. Boyd, Atlanta, Ga.

Dr. Robert Gutierrez, New York, read a paper on "Surgical Aspect of Renal Agenesis with Special Reference to Hypoplastic Kidney, Renal Aplasia and Congenital Absence of One Kidney." Discussed by Drs. C. L. Peacock, New Orleans; Thomas D. Moore, Memphis, Tenn.; I. G. Duncan, Memphis, Tenn.; H. W. E. Walther, New Orleans, and Robert Gutierrez, New York.

Dr. George R. Livermore, Memphis, Tenn., moved that a rising vote of thanks be extended to the urologists of New Orleans for their courtesy and splendid hospitality during the meeting. The motion was seconded and unanimously carried.

## SECTION ON ORTHOPEDIC SURGERY

### Wednesday, May 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. James Warren Sever, Boston.

Dr. Reginald Burbank, New York, read a paper on "Studies on the Etiology and Treatment of Chronic Arthritis." Discussed by Drs. Robert B. Osgood, Boston; Henry W. Meyerding, Rochester, Minn., and Reginald Burbank, New York.

Dr. Wallace S. Duncan, Cleveland, read a paper on "The Relationship of Thyroid Disease to Chronic Nonspecific Arthritis." Discussed by Drs. Henry W. Meyerding, Rochester, Minn.; Ralph Pemberton, Philadelphia; Reginald Burbank, New York, and Wallace S. Duncan, Cleveland.

Dr. James A. Dickson, Cleveland, read a paper on "An Analysis of Two Hundred Cases of Periarthritis of the Shoulder." Discussed by Drs. Myron O. Henry, Minneapolis; W. B. Carrell, Dallas, Texas; Joseph E. Wheeler, Jefferson Barracks, Mo.; Willis C. Campbell, Memphis, Tenn., and James A. Dickson, Cleveland.

Dr. Paul C. Williams, Ann Arbor, Mich., read a paper on "Reduced Lumbosacral Joint Space and Its Relationship to Sciatic Irritation." Discussed by Drs. Fremont A. Chandler, Chicago; Archer O'Reilly, St. Louis; Albert H. Brewster, Boston; James Warren Sever, Boston; Henry W. Meyerding, Rochester, Minn., and Paul C. Williams, Ann Arbor, Mich.

Dr. Philip Lewin, Chicago, read a paper on "The Galeazzi Treatment of Scoliosis." Discussed by Drs. J. H. Kite, Decatur, Ga.; Jacob Kulowski, Iowa City; A. R. Shands, Jr., Dunham, N. C., and Philip Lewin, Chicago.

Dr. Charles LeRoy Lowman, Los Angeles, read a paper on "Postsurgical Use of the Underwater Gymnasium." No discussion.

Thursday, May 12—Afternoon

Dr. J. H. Kite, Decatur, Ga., read a paper on "The Treatment of Congenital Clubfoot." Discussed by Drs. E. S. Hatch, New Orleans, and J. H. Kite, Decatur, Ga.

Dr. Armitage Whitman, New York, read a paper on "An Operative Procedure for the Relief of Congenital Elevation of the Scapula and for Paralysis of the Serratus Magnus Muscle." Discussed by Drs. John Prentiss Lord, Omaha; James A. Dickson, Cleveland; Philip Lewin, Chicago; Francis Carr, Jr., New York, and Armitage Whitman, New York.

Dr. James Warren Sever, Boston, read the chairman's address, entitled "The Crippled Child Versus the Chronic Sick of Massachusetts."

Dr. Chester C. Schneider, Milwaukee, read a paper on "Acromioclavicular Dislocation: Autoplastic Reconstruction." Discussed by Drs. Isidore Cohn, New Orleans; Myron O. Henry, Minneapolis; W. B. Carrell, Dallas, Texas; Philip Lewin, Chicago, and Chester C. Schneider, Milwaukee.

Dr. Rudolph S. Reich, Cleveland, read a paper on "End-Results in Fractures of the Os Calcis." Discussed by Drs. Robert Carothers, Cincinnati; Frank G. Murphy, Chicago; Roland Hammond, Providence, R. I.; J. B. Foster, Houston, Texas, and Rudolph S. Reich, Cleveland.

Friday, May 13—Afternoon

The following officers were elected: chairman, Dr. W. Barnett Owen, Louisville, Ky.; vice chairman, Dr. J. S. Speed, Memphis, Tenn.; secretary, Dr. Fremont A. Chandler, Chicago.

Dr. Albert H. Brewster, Boston, read a paper on "Countersinking the Astragalus in Paralytic Feet." Discussed by Drs. P. A. McIlhenny, New Orleans; W. B. Carrell, Dallas, Texas; J. S. Speed, Memphis, Tenn.; S. L. Hass, San Francisco, and Albert H. Brewster, Boston.

Dr. C. B. Francisco, Kansas City, Mo., read a paper on "Tumors of the Pelvis." Discussed by Drs. Henry W. Meyerding, Rochester, Minn.; J. S. Speed, Memphis, Tenn.; Rudolph S. Reich, Cleveland, and C. B. Francisco, Kansas City, Mo.

Dr. Henry W. Meyerding, Rochester, Minn., moved that the section heartily approve of the plan as submitted by the National Board of Medical Examiners (covering the proposed national examining board) and that it give its hearty cooperation to the committee appointed by the American Orthopedic Society for the furtherance of this movement. The motion was seconded and carried, and the chairman appointed Dr. Philip Lewin, Chicago, Dr. Archer O'Reilly, St. Louis, and Dr. Henry W. Meyerding, Rochester, Minn., as members of a special committee to consider the proposed plan.

Dr. W. Eugene Wolcott, Des Moines, Iowa, read a paper on "Circulation of the Head and Neck of the Femur in Its Relation to Nonunion." Discussed by Drs. Myron O. Henry, Minneapolis; F. J. Gaenslen, Milwaukee; Chester C. Schneider, Milwaukee; P. H. McIlhenny, New Orleans; Robert Carothers, Cincinnati, and W. Eugene Wolcott, Des Moines, Iowa.

Drs. Eugene M. Regen and H. T. Hillstrom, Nashville, Tenn., presented a paper on "An Experimental Study of the Effect of the Roentgen Ray on Bone Growth and on Bone Regeneration." Discussed by Drs. S. L. Haas, San Francisco, and H. T. Hillstrom, Nashville, Tenn.

Dr. John Prentiss Lord, Omaha, read a paper on "Closur of Osteomyelitic Cavities by Plastic Methods." Discussed by Drs. F. J. Gaenslen, Milwaukee, and John Prentiss Lord, Omaha.

Dr. Frank G. Murphy, Chicago, read a paper on "Injuries to the Internal and External Lateral Ligaments of the Knee." Discussed by Drs. C. B. Francisco, Kansas City, Mo.; L. D. Smith, Milwaukee; Paul A. Quaintance, Los Angeles, and Frank G. Murphy, Chicago.

---

## SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

Wednesday, May 11—Morning

The meeting was called to order at 9:15 by the vice chairman, Dr. Curtice Rosser, Dallas, Texas.

Dr. E. G. Martin, Detroit, read a paper on "Prolapse o the Rectum: Its Reclassification and Surgical Treatment." Discussed by Drs. Jerome M. Lynch, New York; Mauri Lescale, New Orleans; Louis J. Hirschman, Detroit; C. C. Meckling, Pittsburgh; Louis A. Buie, Rochester, Minn., and E. G. Martin, Detroit.

Drs. Curtice Rosser and Stuart A. Wallace, Dallas, Texas, presented a paper on "The Pathology of Tumor Formation Consequent to the Injection of Oils under the Rectal Mucosa." Discussed by Drs. Fred D. Weidman, Philadelphia; C. J. de Bere, Chicago; C. C. Tucker, Wichita, Kan.; Louis A. Buie, Rochester, Minn.; Jerome M. Lynch, New York; E. G. Martin, Detroit; Louis J. Hirschman, Detroit; Walter A. Fansler, Minneapolis, and Curtice Rosser, Dallas, Texas.

Dr. George E. Binkley, New York, read a paper on "Colostomy, Radiation Therapy and Perineal Resection for Carcinoma of the Rectum." Discussed by Drs. Curtice Rosser, Dallas, Texas; Dudley A. Smith, San Francisco, and George E. Binkley, New York.

Dr. Dudley A. Smith, San Francisco, read a paper on "The Status of Colostomy." Discussed by Drs. Fred W. Rankin, Rochester, Minn.; Louis J. Hirschman, Detroit; Alton Ochsner New Orleans; C. C. Meckling, Pittsburgh, and Dudley A. Smith, San Francisco.

Dr. Sara M. Jordan, Boston, read a paper on "The Unstable Colon and Neurasthenia." Discussed by Drs. John G. Mateer, Detroit; Julius Friedenwald, Baltimore; Henry A. Rafsky, New York; Sidney K. Simon, New Orleans; Seale Harris, Birmingham, Ala.; Sidney A. Portis, Chicago, and Sara M. Jordan, Boston.

Thursday, May 12—Morning

Dr. George B. Eusterman, Rochester, Minn., read the chairman's address, entitled "Notes on Problems and Progress in Gastro-Enterology."

The following papers were read as a symposium on "Experimental Work in Peptic Ulcer":

Drs. F. C. Mann and J. L. Bollman, Rochester, Minn.: "Observations on the Development and Treatment of Experimentally Produced Peptic Ulcers." Discussed by Dr. I. S. Ravdin, Philadelphia.

Drs. A. C. Ivy and S. J. Fogelson, Chicago: "Experimental and Clinical Observations on Gastric Mucin in 'Peptic Ulcer.'" Discussed by Drs. George B. Eusterman, Rochester, Minn., and Martin G. Vorhaus, New York.

Dr. Lewis Gergory Cole, New York: "Process of Repair of Gastric Ulcer." Discussed by Drs. Charles W. Duval, New Orleans, and Owen H. Wangensteen, Minneapolis.

Dr. Frank Smithies, Chicago: "A Clinical Consideration of the Therapeutic Worth of Mucin in the Treatment of Peptic Ulcer."

Dr. Henry A. Rafsky, New York: "The Relation of Alkalosis to Peptic Ulcer." Discussed by Drs. L. J. Hardt, Chicago, and James B. Eyerly, Chicago.

The symposium as a whole was discussed by Drs. Sidney A. Portis, Chicago; Robert Kapsinow, Lafayette, La.; J. L. Bollman, Rochester, Minn.; A. C. Ivy, Chicago; A. F. R. Andresen, Brooklyn; S. J. Fogelson, Chicago; Frank Smithies, Chicago; Lewis Gregory Cole, New York; Julius Friedenwald, Baltimore, and Harry A. Rafsky, New York.

Drs. George W. Holmes and Aubrey O. Hampton, Boston, presented a paper on "The Instances of Carcinoma in Chronic

Ulcerating Lesions of the Stomach." Discussed by Drs. John D. Camp, Rochester, Minn.; Frank Smithies, Chicago; Martin E. Rehfuss, Philadelphia; Lewis Gregory Cole, New York, and George W. Holmes, Boston.

Friday, May 13—Morning

The following officers were elected: chairman, Dr. Curtice Rosser, Dallas, Texas; vice chairman, Dr. A. F. R. Andresen, Brooklyn; secretary, Dr. H. L. Bockus, Philadelphia; delegate, Dr. Descum C. McKenney, Buffalo; alternate, Dr. Sara M. Jordan, Boston.

Dr. Burrill B. Crohn, New York, presented a resolution on the death of Dr. Percy B. Davidson, which on motion of Dr. Martin E. Rehfuss, Philadelphia, duly seconded, was unanimously adopted.

Dr. Martin E. Rehfuss, Philadelphia, read a paper on "Demonstration of a Hormone-Like Element Capable of Affecting the Small Intestinal Contractions." Discussed by Drs. A. C. Ivy, Chicago; Daniel N. Silverman, New Orleans; Seizaburo Okada, Nagoya, Japan, and Martin E. Rehfuss, Philadelphia.

Dr. Burrill B. Crohn, New York, read a paper on "Terminal Ileitis: Its Clinical Manifestations." Discussed by Drs. J. A. Bargen, Rochester, Minn.; Julius Friedenwald, Baltimore; Louis J. Hirschman, Detroit; Sidney A. Portis, Chicago, and Burrill B. Crohn, New York.

Drs. Wallace M. Yater and Laurence S. Otell, Washington, D. C., presented a paper on "The Differential Diagnosis of Diseases of the Liver and Spleen with the Aid of Roentgenography After the Intravenous Injection of Thorium Dioxide." Discussed by Drs. William H. Harris, New Orleans; C. J. Tripoli, New Orleans; Oscar Hite, Richmond, Va., and Wallace M. Yater, Washington, D. C.

Drs. William E. Robertson, William A. Swalm and Frank W. Konzelmann, Philadelphia, presented a paper on "Comparative Merits of the Five Most Popular Tests for Determining the Functional Capacity of the Liver." Discussed by Drs. John A. Killian, New York; Donovan C. Browne, New Orleans; Sidney A. Portis, Chicago; J. E. Hirsh, Birmingham, Ala.; L. A. Crandall, Chicago; George B. Eusterman, Rochester, Minn., and William E. Robertson, Philadelphia.

Drs. Julius Friedenwald and Samuel Morrison, Baltimore, presented a paper on "Clinical Observation on the Relation of Gastric and Renal Disorders." Discussed by Drs. Sidney K. Simon, New Orleans; Seale Harris, Birmingham, Ala.; A. L. Levin, New Orleans, and Julius Friedenwald, Baltimore.

The following Committee on Scientific Exhibit was appointed: Dr. A. H. Aaron, Buffalo, chairman; Dr. W. A. Fansler, Minneapolis, and Dr. A. F. R. Andresen, Brooklyn.

## SECTION ON RADIOLOGY

Wednesday, May 11—Morning

The meeting was called to order at 9:05 by the chairman, Dr. Henry K. Pancoast, Philadelphia.

Dr. John W. Pierson, Baltimore, and Dr. Charles L. Martin, Dallas, Texas, were appointed to serve on the Executive Committee as substitutes for Dr. Fred M. Hodges, Richmond, Va., and Dr. Arthur W. Erskine, Cedar Rapids, Iowa.

Dr. Henry K. Pancoast, Philadelphia, read the chairman's address, entitled "The Superior Pulmonary Sulcus Tumor."

Dr. Maurice Lenz, New York, read a paper on "Roentgenotherapy of Malignant Neoplasms of the Upper Respiratory Tract." Discussed by Drs. Francis Carter Wood, New York, and Maurice Lenz, New York.

Dr. A. U. Desjardins, Rochester, Minn., read a paper on "Radiotherapy for Hodgkin's Disease and Lymphosarcoma." Discussed by Drs. John H. Musser, New Orleans; Dr. Walter L. Mattick, Buffalo, and A. U. Desjardins, Rochester, Minn.

Dr. Charles L. Martin, Dallas, Texas, read a paper on "Small Radium Needle Technic." Discussed by Drs. Maurice Lenz, New York; W. E. Costolow, Los Angeles; A. James Larkin, Chicago, and Charles L. Martin, Dallas.

Dr. Edwin C. Ernst, St. Louis, read a paper on "Radiologic Research: Its Significance in Medicine." Discussed by Dr. Albert Soiland, Los Angeles.

Dr. Walter L. Mattick, Buffalo, read a paper on "Protracted Treatment with Heavily Filtered High Voltage Roentgen Irradiation in Its Application to Cancer Therapy." Discussed by Drs. A. U. Desjardins, Rochester, Minn.; John T. Murphy, Toledo, Ohio, and Walter L. Mattick, Buffalo.

Thursday, May 12—Morning

Dr. Arthur C. Christie, Washington, D. C., was appointed to serve on the Executive Committee in place of Dr. Charles L. Martin, Dallas, Texas, who was called home.

Dr. C. H. Heacock, Memphis, Tenn., read a paper on "Calcification in Intestinal Tuberculosis." Discussed by Drs. P. F. Butler, Boston, and C. H. Heacock, Memphis, Tenn.

Drs. P. F. Butler and Max Ritvo, Boston, presented a paper on "Physostigmine, a Peristaltic Stimulant." Discussed by Drs. Ernest C. Samuel, New Orleans; L. R. Sante, St. Louis, and P. F. Butler, Boston.

Dr. John W. Pierson, Baltimore, read a paper on "Pneumonia Due to the Aspiration of Lipoids." Discussed by Drs. W. Walter Wasson, Denver; John F. Herrick, Ottumwa, Iowa; J. L. Dubrow, Memphis, Tenn., and John W. Pierson, Baltimore.

Dr. Barnet P. Stivelman, New York, read a paper on "Atelectasis in Pulmonary Tuberculosis." Discussed by Drs. L. R. Sante, St. Louis; Henry K. Pancoast, Philadelphia; Lawrence Reynolds, Detroit; J. L. Dubrow, Memphis, Tenn.; John W. Pierson, Baltimore, and Barnet P. Stivelman, New York.

Dr. Arthur C. Christie, Washington, D. C., read a paper on "The Education and Certification of Radiologists." Discussed by Drs. Henry K. Pancoast, Philadelphia; P. F. Butler, Boston; George W. Grier, Pittsburgh, and Leon J. Menville, New Orleans.

Drs. Ira H. Lockwood and Wendell Stewart, Kansas City, Mo., presented a paper on "A Roentgen Study of the Physiologic and Pathologic Changes in the Mammary Gland." Discussed by Drs. Leon J. Menville, New Orleans; Eugene P. Pendergrass, Philadelphia, and Ira H. Lockwood, Kansas City, Mo.

Friday, May 13—Morning

The following officers were elected: chairman, Dr. George W. Grier, Pittsburgh; vice chairman, Dr. W. Walter Wasson, Denver; secretary, Dr. John T. Murphy, Toledo, Ohio; delegate, Dr. Albert Soiland, Los Angeles; alternate, Dr. A. U. Desjardins, Rochester, Minn.

Dr. Arthur C. Christie, Washington, D. C., moved the adoption of the following resolution:

> Whereas, It is considered desirable to establish some method for control of the practice of radiology; and
>
> Whereas, Certain medical specialties have established boards for certification of specialists in their respective fields; and
>
> Whereas, The boards above mentioned have operated successfully over varying periods of years to the great advantage of the specialties which they represent; be it therefore
>
> *Resolved*, That the Section on Radiology of the American Medical Association request the Board of Trustees to appoint a committee of two to confer with the American Roentgen Ray Society, the Radiological Society of North America, the American College of Radiology, and the American Radium Society, with the object of forming an American Board for Radiologic Examinations; and be it further
>
> *Resolved*, That any plan presented by the above named committee shall take effect and be put into operation only after approval by the Board of Trustees and by at least two of the above mentional national radiologic organizations.

The motion was regularly seconded, was put to a vote and carried.

Dr. John D. Camp, Rochester, Minn., read a paper on "A Roentgenologic Study of the Osseous Changes in Hyperparathyroidism." Discussed by Drs. Lawrence Reynolds, Detroit; Plinn F. Morse, Detroit; C. S. Gorsline, Battle Creek; Nathaniel Gates, Detroit; Henry K. Pancoast, Philadelphia; Philip Lewin, Chicago, and John D. Camp, Rochester, Minn.

Dr. A. Jerome Thomas, Shreveport, La., read a paper on "Radiographic Researches of Pregnancy Featuring the Early Diagnosis." Discussed by Drs. Amédée Granger, New Orleans; J. T. Murphy, Toledo, Ohio; Henry K. Pancoast, Philadelphia, and A. Jerome Thomas, Shreveport, La.

Dr. Bundy Allen, Tampa, Fla., read a paper on "Roentgenographic and Clinical Observations of the Nasal Accessory Sinuses."

Dr. W. Walter Wasson, Denver, read a paper on "The Changes Taking Place in the Nasal Accessory Sinuses After Birth."

These two papers were discussed by Drs. Amédée Granger, New Orleans; Edwin C. Ernst, St. Louis; Eugene P. Pendergrass, Philadelphia; Bundy Allen, Tampa, Fla., and W. Walter Wasson, Denver.

Dr. Roy G. Giles, Temple, Texas, read a paper on "Fractures of the Spine: Report of One Hundred and Seventy-Three Cases." No discussion.

# THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the New Orleans session was of especial interest because of the diversified character of the exhibits. Twelve sections of the Scientific Assembly sponsored group exhibits, with forty-two individuals reading papers before the sections who also had exhibits on the same subjects in the Scientific Exhibit.

Three special exhibits authorized by the Board of Trustees were shown for the first time this year. The exhibit on poliomyelitis was a cooperative undertaking by the Committee on Scientific Exhibit, the United States Public Health Service, and six sections of the Scientific Assembly. The exhibit occupied seven booths, at which demonstrations were given at stated intervals, and was accompanied by a pamphlet written for the occasion for distribution to visitors. The committee in charge of the exhibit was composed of John E. Gordon, Detroit; Arthur T. Legg, Boston, and Ralph C. Williams, chairman, Washington, D. C. The active committee was assisted by an advisory committee composed of William H. Park, New York, representing the Section on Pathology and Physiology; J. C. McKinley, Minneapolis, representing the Section on Nervous and Mental Diseases; Kenneth D. Blackfan, Boston, representing the Section on Pediatrics; Walter Truslow, Brooklyn, representing the Section on Orthopedic Surgery; Franklin E. Murphy, Kansas City, Mo., representing the Section on Practice of Medicine, and S. D. Kramer, Boston, representing the Section on Preventive and Industrial Medicine and Public Health. Demonstrations on different phases of poliomyelitis were given by W. Lloyd Aycock, Boston; S. D. Kramer, Boston; John E. Gordon, Detroit; E. B. Shaw, San Francisco; James L. Wilson, Boston; J. P. Leake, Washington; Arthur T. Legg, Boston, and Janet B. Merrill, Boston.

The exhibit on cancer was in charge of a committee composed of Max Cutler, Chicago, R. S. Ferguson, New York, and Frank W. Hartman, chairman, Detroit, assisted by the following demonstrators: A. C. Broders, Rochester, Minn.; H. P. Doub, Detroit; Charles F. Geschickter, Baltimore; John G. Mateer, Detroit; J. P. Pratt, Detroit, and Shields Warren, Boston. A continuous program of illustrated lectures and motion pictures was carried on in connection with the exhibit as a joint endeavor with the American Society for the Control of Cancer.

The exhibit on physical therapy occupied four booths with continuous demonstrations. The committee was as follows: K. G. Hansson, New York; C. L. Lowman, Los Angeles, and John S. Coulter, chairman, Chicago.

The Section on Diseases of Children included in its group fourteen exhibits on a variety of subjects, two of which received a certificate of merit. The committee in charge was composed of A. Graeme Mitchell, Cincinnati; Robert A. Strong, New Orleans, and F. Thomas Mitchell, chairman, Memphis, Tenn.

The Section on Practice of Medicine showed twelve exhibits, to which were awarded one gold medal and one silver medal. James H. Austin, Philadelphia, Eugene S. Kilgore, San Francisco, and L. G. Rowntree, chairman, Rochester, Minn., formed the committee in charge.

The Section on Dermatology and Syphilology, under the direction of a committee composed of John A. Devron, New Orleans, Clark W. Finnerud, Chicago, Robert L. Gilman, Philadelphia, and Fred D. Weidman, chairman, Philadelphia, continued its work on the relation of dermatology to systemic conditions. In addition to the group exhibit there were several other exhibits, one of which was awarded a silver medal and one a certificate of merit.

The Section on Preventive and Industrial Medicine and Public Health sponsored eight exhibits, to one of which was given a certificate of merit. The committee in charge was as follows: Alice Hamilton, Boston; E. R. Hayhurst, Columbus, Ohio, and Paul A. Davis, chairman, Akron, Ohio.

The Section on Nervous and Mental Diseases sponsored a motion picture program shown in a space adjoining its exhibits. The committee in charge was composed of Earl D. Bond, Philadelphia; Groves B. Smith, Godfrey, Ill., and Thomas J. Heldt, chairman, Detroit.

The Section on Obstetrics, Gynecology and Abdominal Surgery, with a committee composed of Norman F. Miller, Ann Arbor, Mich.; T. B. Sellers, New Orleans, and E. D. Plass, chairman, Iowa City, placed special emphasis on its motion picture program shown in conjunction with the exhibits.

The Section on Ophthalmology, in addition to the exhibits, showed motion pictures in an adjoining space. The committee in charge was composed of C. A. Bahn, New Orleans; G. L. Hardin, New Orleans, and Parker Heath, chairman, Detroit.

The Section on Laryngology, Otology and Rhinology, under the auspices of a committee composed of F. E. Lejeune, New Orleans; William A. Wagner, New Orleans, and Austin A. Hayden, chairman, Chicago, besides its exhibit, carried on a motion picture program at which seventeen films were shown on a continuous schedule.

The Section on Orthopedic Surgery had two exhibits in conjunction with a motion picture program. The committee in charge was composed of Paul N. Jepson, Philadelphia; J. T. O'Ferrall, New Orleans, and E. B. Mumford, chairman, Indianapolis.

The Section on Gastro-Enterology and Proctology, with a committee made up of Curtice Rosser, Dallas, Texas; F. D. Gorham, St. Louis, and A. H. Aaron, chairman, Buffalo, showed six exhibits.

The Section on Radiology sponsored seven exhibits besides the large amount of radiologic material found in the exhibits of other sections. The committee was as follows: Amédée Granger, New Orleans; Ernest C. Samuel, New Orleans, and Charles L. Martin, chairman, Dallas, Texas.

The Section on Urology took part in the Scientific Exhibit under the auspices of a committee of which George Gilbert Smith was chairman.

Besides three special exhibits and seventy exhibits under the auspices of different sections, there were thirteen pathologic and laboratory exhibits, eight surgical and anatomic and twenty-two in the educational classification, making 116 in all.

# REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards reports:

### CLASS I

[Awards in Class I are made for exhibits of individual investigations, which are judged on the basis of originality and excellence of presentation.]

The gold medal to Frank A. Hartman, C. W. Greene, J. J. Maisel and G. W. Thorn, University of Buffalo, Buffalo, for original investigative work on the development and use of a hormone from the suprarenal cortex and excellence of presentation.

The silver medal to C. W. Emmons, College of Physicians and Surgeons, Columbia University, New York, for original work on the variations in ringworm fungi and excellence of presentation.

The bronze medal to J. A. Bargen, P. W. Brown and H. M. Weber, Mayo Clinic and Mayo Foundation, Rochester, Minn., for original investigation of diseases of the colon and excellence of presentation.

Certificates of Merit, Class I, were awarded to the following (alphabetically arranged):

To Abraham Levinson, Chicago, for exhibit illustrating continuation of investigations on the cerebrospinal fluid.

To Alton Ochsner, Earl Garside and Ambrose Storck, Department of Surgery, Tulane University Medical School, New

Orleans, for exhibit illustrating the use of digestive ferments in prevention of adhesions.

To Sidney J. Wilson and Simeon H. Hulsey, Fort Worth, Texas, and Fred D. Weidman, Philadelphia, for exhibit illustrating excellent studies on chromoblastomycosis in Texas.

In addition, the following exhibit is deemed worthy of Honorable Mention:

That of John W. Towey, Powers, Mich., Willis H. Huron, Iron Mountain, Mich., and Henry C. Sweany, Chicago, for exhibit on occupational sensitization to fungus spores found in maple bark.

### CLASS II

[Awards in Class II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of correlating facts and excellence of presentation.]

The gold medal to Max Ballin and Plinn F. Morse, Harper Hospital, Detroit, for excellence of presentation of exhibit on parathyroidism.

The silver medal to L. G. Rowntree and C. H. Greene, Mayo Clinic and Mayo Foundation, Rochester, Minn., for excellence of presentation of exhibit of comprehensive study on Addison's Disease.

The bronze medal to Ernest Carroll Faust, Department of Tropical Medicine, Tulane University Medical School, New Orleans, for excellence of presentation of exhibit on human helminth infections.

Certificates of Merit, Class II, were awarded to the following (alphabetically arranged):

To Chevalier Jackson and Chevalier L. Jackson, Temple University School of Medicine, Philadelphia, for excellence of presentation of exhibit illustrating tumors of the lungs and tracheobronchial tree.

To Frank C. Neff, D. N. Medearis and Margaret Anderson, Department of Pediatrics, University of Kansas School of Medicine, Kansas City, Kan., for excellence of presentation of exhibit illustrating a study of the newly born.

To Henry F. Vaughan, Detroit Department of Health, Detroit, for excellence of presentation of exhibit illustrating plan of medical participation of the general practitioner in a public health program.

In addition, the following exhibits are deemed worthy of Honorable Mention:

That of Francis Clark Grant, University Hospital, Philadelphia, for excellence of demonstration of exhibit on ventriculography.

That of O. E. Denney, National Leprosarium, Carville, La., for exhibit on leprosy. (This work has been recognized by awards at previous Scientific Exhibits of the American Medical Association.)

The Committee on Awards commends especially the group exhibit of the Mayo Clinic and Mayo Foundation as a model of presentation.

### EDUCATIONAL CLASSIFICATION

A special Certificate of Merit is awarded to the American Society for the Control of Cancer for a cooperative exhibit on cancer as the best exhibit in the educational (national organizations) classification.

The Committee on Awards commends the excellent demonstrations given in the special exhibits; namely, the exhibit on poliomyelitis, that on cancer and that on physical therapy.

The Committee on Awards extends to the Committee on Scientific Exhibit, to the Advisory Committee and to Dr. Thomas G. Hull, executive in charge, and to the active participants in the Scientific Exhibit, its appreciation. The committee feels that the Scientific Exhibit continues to be an extremely important and distinctive feature of the annual session.

The committee also wishes to state that the cooperation of the twelve sections in arranging special exhibits has been of great value.

Henry E. Helmholz, Chairman, Rochester, Minn.
Frank W. Hartman, Detroit.
Roger I. Lee, Boston.
Thomas G. Orr, Kansas City, Mo.
Eugene P. Pendergrass, Philadelphia.

## REGISTRATION AT NEW ORLEANS

The total registration at the New Orleans session was 2,778. Below are given two summaries—one by sections and one by states:

*Registration by Sections*

| | |
|---|---|
| Practice of Medicine | 725 |
| Surgery, General and Abdominal | 526 |
| Obstetrics, Gynecology and Abdominal Surgery | 204 |
| Ophthalmology | 172 |
| Laryngology, Otology and Rhinology | 168 |
| Diseases of Children | 198 |
| Pharmacology and Therapeutics | 24 |
| Pathology and Physiology | 90 |
| Nervous and Mental Diseases | 99 |
| Dermatology and Syphilology | 84 |
| Preventive and Industrial Medicine and Public Health | 112 |
| Urology | 107 |
| Orthopedic Surgery | 67 |
| Gastro-Enterology and Proctology | 67 |
| Radiology | 98 |
| Miscellaneous (two or more sections or no section marked) | 37 |
| Total | 2,778 |

*Registration by States*

| | | | |
|---|---|---|---|
| Alabama | 104 | New Hampshire | 1 |
| Arizona | 3 | New Jersey | 22 |
| Arkansas | 49 | New Mexico | 4 |
| California | 71 | New York | 156 |
| Colorado | 38 | North Carolina | 17 |
| Connecticut | 11 | North Dakota | 3 |
| District of Columbia | 35 | Ohio | 97 |
| Florida | 62 | Oklahoma | 49 |
| Georgia | 57 | Oregon | 7 |
| Idaho | 2 | Pennsylvania | 107 |
| Illinois | 156 | Rhode Island | 3 |
| Indiana | 46 | South Carolina | 24 |
| Iowa | 31 | South Dakota | 3 |

# *Association News*

## ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD
## MAY 7-12, 1932

Meetings of the Board of Trustees were held at the Roosevelt Hotel, New Orleans, on Sunday, May 7, and on ensuing days during the annual session of the Association.

### REPRESENTATIVE ON SECTION N OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

Dr. William H. Park was appointed to represent the American Medical Association on section N of the American Association for the Advancement of Science.

### DISCHARGE OF COMMITTEES TO STUDY ANESTHESIA ACCIDENTS

It was deemed advisable to dissolve the two special committees on anesthesia of the Council on Pharmacy and Chemistry, to ask the Council on Scientific Assembly to discharge its Committee on Anesthesia, to ask the secretary of the Council on Pharmacy and Chemistry to receive reports of accidents and to transmit them to the respective referees for advice, and to request the chairman of the Council to appoint special investigating committees if need arises.

### POSTPONEMENT OF PUBLICATION OF THE THIRTEENTH EDITION OF THE AMERICAN MEDICAL DIRECTORY

Since it appears reasonably certain that because of the financial depression it will not be possible to issue a new edition of the American Medical Directory in 1933 without serious loss, it was decided to postpone the publication of the thirteenth edition until 1934.

### REPRESENTATIVES TO MEETING OF BRITISH MEDICAL ASSOCIATION

Dr. George H. Simmons, Dr. Edmund Horgan and Dr. Henry O. Reik were appointed to represent the American Medical Association at the meeting of the British Medical Association to be held in July.

### ELIMINATION OF ADVERTISEMENTS OF DIATHERMY APPARATUS MANUFACTURED BY FIRMS THAT PROVIDE CLINICAL INSTRUCTIONS IN PHYSICAL THERAPY PROCEDURES

The Board of Trustees voted to instruct the Advertising Committee of the Association not to accept advertisements of diathermy apparatus manufactured by firms that employ persons to give clinical instruction in physical therapy procedures.

### SERIES OF ARTICLES ON ELECTROCARDIOGRAPHY

The Board approved the publication in The Journal, and later in book form, of a series of articles on electrocardiography, which, it is hoped, will provide light on the subject for the general practitioner.

### RESOLUTIONS FROM THE HOUSE OF DELEGATES

Resolutions referred to the Board of Trustees by the House of Delegates were given careful consideration and reports on these were made to the House.

### JOINT MEETING OF BOARD OF TRUSTEES AND SPECIAL JOURNAL EDITORS

Provisions were made for a joint meeting of the Board of Trustees with the editors of the special journals published by the American Medical Association during the week of the meeting in Milwaukee in 1933.

### APPRECIATION OF SERVICE RENDERED BY MEMBERS OF COUNCILS

The editor of The Journal was instructed to prepare for publication an editorial pointing out the service rendered by members of the various councils and the amount of time required to perform that service, so that the medical profession may have a clearer idea of what the members of these councils are doing for the Association without remuneration.

### REORGANIZATION OF BOARD OF TRUSTEES

At its last meeting, on Thursday, the Board of Trustees reorganized and the following officers and committees were appointed: Dr. A. R. Mitchell, Chairman; Dr. J. H. J. Upham, Vice Chairman; Dr. J. H. Walsh, Secretary. Executive Committee and Finance Committee: Drs. J. H. J. Upham, Rock Sleyster and J. H. Walsh. Committee on Scientific Exhibit: Drs. D. Chester Brown (Chairman), A. W. Booth and Allen Bunce.

The date of the September meeting of the Board was fixed as September 22 and 23.

Other matters also were given careful consideration.

## MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 1:30 to 1:35 p. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia Chain Program has been discontinued for the present.

The program for the week is as follows:

May 30. Holiday (no broadcast).
June 1. Granny Magic.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM.

The program for the week is as follows:

June 4. How is Your Blood Pressure?

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

# Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

## CALIFORNIA

**Society News.**—Dr. James Vernon Luck, among others addressed the Los Angeles County Medical Association, May 19, on "The Schilling Differential in Appendicitis."——Included among the speakers before the Los Angeles Clinical and Pathological Society, May 26, was Dr. Clifford B. Walker on "Traumatic Bitemporal Hemianopsia with Analysis of Mechanism."——The Society for Neurology and Psychiatry was addressed, May 25, among others, by Dr. E. Huntington Williams on "Experiences with Sodium Rhodanate in Narcolepsy and Allied Conditions."

**Urge Change in Laws Relating to Commitment of Insane.**—A campaign for the improvement of California laws relating to the commitment of the insane was started at a meeting of county and state officials, welfare leaders and hospital executives at the University of California. Dr. Herman M. Adler, professor of psychiatry, University of California Medical School, Berkeley, presided, and the discussion was led by Dr. Glenn E. Myers, Los Angeles. It was pointed out that the commitment laws are antiquated, cumbersome and make humane examination and treatment of those suffering from mental disease almost impossible. The consensus of the group was that "it should be made as easy as possible for a person deserving treatment of a mental disorder to get into a California state hospital through the provision of the voluntary admission rule. Such voluntary admission should be encouraged, not discouraged."

## DISTRICT OF COLUMBIA

**District Bill in Congress.**—S. 4704, by Senator Blaine, Wisconsin, to amend the healing arts practice act of the District of Columbia to provide that the act shall not be construed so as to deny a license by reciprocity "to physicians who were licensed prior to 1905."

**District Medical Election.**—Dr. Harry A. Fowler was elected president of the Medical Society of the District of Columbia at its annual meeting, May 4. Other officers of the society are Drs. Henry R. Schreiber and Helen Gladys Kain, vice presidents, and Coursen B. Conklin, secretary. The next annual meeting will be held, May 3, 1933.

**Appointments at George Washington University.**—The following new appointments to the teaching staff of the George Washington University School of Medicine, Washington, D. C., for the coming academic year have been announced, among others:

Dr. Errett Cyril Albritton, professor of physiology and executive officer of the department.
Vincent du Vigneaud, Ph.D., professor of biochemistry and executive officer of the department.
Leland W. Parr, Ph.D., associate professor of bacteriology.
Dr. Roscoe Roy Spencer, associate professor of hygiene and preventive medicine.
Chester E. Leese, Ph.D., assistant professor of physiology.
John H. Hanks, Ph.D., assistant professor of bacteriology.
Elizabeth Verder, Ph.D., assistant professor of bacteriology.
Dr. William H. Jenkins, clinical professor of otorhinolaryngology.
Dr. Loren B. T. Johnson, associate in pediatrics.
Dr. Edgar M. McPeak, associate in radiology.
Dr. Isidore Lattman, associate in radiology.
Dr. Montgomery Blair, Jr., clinical instructor in pediatrics.
Dr. Jeter C. Bradley, clinical instructor in otorhinolaryngology.
Dr. Paul F. Dickens, clinical instructor in medicine.
Dr. Addison M. Duvall, clinical instructor in psychiatry.
Dr. Bernard L. Hardin, Jr., clinical instructor in medicine.
Dr. George A. Holm, clinical instructor in medicine.
Dr. Spencer V. Meade, clinical instructor in medicine.
Dr. William G. Young, clinical instructor in urology.
Dr. Samuel A. Silk, clinical instructor in psychiatry.

## FLORIDA

**Radiologic Meeting.**—Dr. Orion O. Feaster, St. Petersburg, was elected president of the Florida Radiological Society at its meeting in Sarasota, May 2; Dr. Frederick K. Herpel, West Palm Beach, was made vice president, and Dr. W. McL. Shaw, Jacksonville, secretary. Informal presentation of case reports and demonstrations of roentgenograms were features of a morning and an afternoon session. The society was organized, Nov. 14, 1931.

**State Medical Election and Program.**—Dr. Gerry R. Holden, Jacksonville, was elected president of the Florida

Medical Association at its fifty-ninth annual convention in Sarasota recently, succeeding Dr. Gaston H. Edwards, Orlando. The vice presidents are Drs. Jack Halton, Sarasota, Eugene G. Peek, Ocala, and William C. Thomas, Gainesville. Dr. Shaler A. Richardson, Jacksonville, was reelected secretary. The next annual meeting of the association will be held in Hollywood. Dr. Walter L. Bierring, Des Moines, Iowa, guest of honor at this meeting, spoke on "Present Status of Heart Lesions." Drs. Simon E. Driskell, Jacksonville, spoke on "A Proposed Compensation Act and Its Relation to the Physician"; Spencer A. Folsom, Orlando, "Modern Treatment of Thyrotoxicosis"; Frank C. Metzger, Sarasota, "Hay Fever in Florida"; Roscoe H. Knowlton, St. Petersburg, "Diabetes in the Home"; Robert G. Nelson, Tampa, "Amelioration of Labor Pains"; Gideon Timberlake, St. Petersburg, "Urinary Obstruction: Recognition of Cause and Its Relief," and Mozart A. Lischkoff, Pensacola, "Recent Progress in Juvenile Sinusitis."

## ILLINOIS

**Society News.**—The Lincoln County Medical Society was addressed, April 22, at Lincoln, by Dr. Jonas Curtis Lyter, St. Louis, on diseases of the coronary arteries.——Dr. William T. Coughlin, St. Louis, discussed "Brain Tumors That Are Overlooked" before the St. Clair County Medical Society in East St. Louis, May 5.——A symposium on nephritis constituted the program of the Adams County Medical Society, Quincy, May 9; the speakers were Drs. Richard A. Harris, Walter M. Whitaker and Seldon R. Hoover, Jr., all of Quincy. ——Dr. Ben Z. Rappaport, Chicago, addressed the Peoria City Medical Society, May 3, on "Diagnosis and Treatment of the Common Allergic Conditions."

### Chicago

**Rush Medical College Holds Alumni Reunion.**—Alumni of Rush Medical College will hold their annual reunion, beginning June 9 and continuing through June 15. Clinics will be held on June 13 at Rush Medical College and on June 14 at Billings Hospital. On June 13 the classes of 1882 and 1912 will meet at special banquets.

**Society News.**—Dr. Sidney J. Silbar, Milwaukee, addressed the Chicago Urological Society, May 25, on "Pain as a Diagnostic and Prognostic Symptom in Gonorrhea."——The Chicago Council of Medical Women will be addressed, June 3, by Drs. Katharine M. Howell on "Vaccine Therapy in Arthritis," and Ernestine V. Kandel, "Blood Findings and Therapy in the Anemias."

**Licenses Revoked.**—The state department of registration and education at Springfield revoked the licenses of Drs. Thomas J. Ney and Wilhelm Loeser, April 13. Dr. Ney's license, which was issued in 1922, was revoked on the ground of his conviction of manslaughter. The license of Dr. Loeser, which was issued in 1905, was revoked because he was found guilty of violation of the Harrison Narcotic Act. Dr. Clifford Judson Spruce's license was revoked, May 2, on the ground of his connection with unlicensed persons. The license of Dr. Maurice J. Rabbins was suspended for one year, April 13, because of his conviction of violation of the Harrison Narcotic Act.

**Gilmore Memorial Foundation.**—The Eugene S. Gilmore Memorial Foundation was recently established in honor of the late Mr. Gilmore, superintendent of Wesley Memorial Hospital for twenty-five years. He was also a past president of the American Hospital Association and its senior trustee. The purpose of the foundation is to create a fund, the income of which will be used in establishing scholarships for the graduates of Wesley Memorial Hospital School of Nursing. The fund will also provide for a tablet or medallion, which will be placed in the new Wesley Memorial Hospital when it is completed. Subscriptions are being received by Dr. Mark T. Goldstine, treasurer of the foundation.

**Gibbs Medal Awarded.**—Edward Curtis Franklin, Ph.D., professor emeritus of organic chemistry, Stanford University, California, was presented with the Willard Gibbs Medal of the Chicago section of the American Chemical Society, May 20. Dr. Franklin is the twenty-first Gibbs medalist to receive the award for "eminent work in and contribution to pure or applied chemistry," the particular field in this case being researches wherein liquid ammonia would be substituted for many important reactions involving water. Dr. Franklin received the degree of doctor of philosophy from Johns Hopkins University in 1894. He was professor of chemistry and chief of the division of chemistry, U. S. Public Health Service, 1911-1913. In 1903 he joined the faculty of Stanford University as associate professor of organic chemistry.

## IOWA

**Society News.**—Dr. Archibald F. O'Donoghue, Sioux City, among others, addressed the Crawford County Medical Society, April 12, in Denison, on "Traction and Extension in Fractures."——The Dallas-Guthrie Counties Medical Society was addressed in Panora, April 21, by Drs. Charles A. Nicoll, Linden, and William R. Van Duzer, Casey, on "Management of Infants Under One Year" and "Diseases of Old Age," respectively.——Dr. Ralph A. Reis, Chicago, addressed the Scott County Medical Society, April 5, on "Appendicitis in Pregnancy."——At the April 22 meeting of the Tama County Medical Society in Dysart, Dr. Frank R. Peterson, Iowa City, talked on recent methods of diagnosis and treatment of carcinoma of the breast.

## MARYLAND

**Twins in Maryland.**—In every fifty live births in Maryland last year, the state department of health reports, there was an average of one set of twins. The total number of live births recorded in the state in 1931 was 28,765. This number includes 298 sets of twins, 596 children, or 2 per cent of the total. In the total of 2,233,149 births in the birth registration area of the United States, it was stated, there were 23,863 sets of twins, 47,726 children, or 2 per cent of the total. These figures, like those for Maryland, do not include the plural births in which one or both children died. The figures for Maryland last year indicate that one set of living twins was born to each 100 mothers.

**Survey of School Children.**—About 75 per cent of the school children in Anne Arundel County have one or more physical defects, according to a report of a survey just completed for the state health department by the director of the county health department. In this survey, which required repeated visits to the seventy-three grammar schools in the county, 5,200 children were examined and 9,000 inspections for communicable diseases were made. Seventy-one per cent of the white children examined and 81 per cent of the Negroes were defective. In both classes dental defects predominated. Local health workers will follow up these examinations by visiting the children's homes. The Anne Arundel unit was established as a "model" organization in August, 1931. It is maintained by the Rockefeller Foundation, Johns Hopkins School of Hygiene and Public Health, the Anne Arundel County commissioners and the state department of health.

**Review Course for General Practitioners.**—The division of medical extension of the University of Maryland announces its ninth annual review course for physicians, beginning June 6 and extending to June 24. This is a general course, designed to give to the physician in general practice the opportunity to study methods of diagnosis and treatment in current use in the university clinics. Preference will be given to physicians registered in Maryland. A matriculation fee of $25 will be charged to these registrants, while a charge of $50 will be made to those coming from other states. Morning lectures will deal with modern advances in diagnosis and treatment, the subjects to be chiefly in the field of general medicine and surgery, with a few lectures devoted to specialties. There will be a daily clinic. The class, which has been limited to twenty, will be assigned in groups in rotation to the dispensary clinics for pediatrics, genito-urinary diseases, syphilis and gastro-intestinal diseases. In the afternoon periods, instruction will be given in the laboratory methods of diagnosis. Electrocardiography and the interpretation of electrocardiograms will be briefly presented. Complete information may be obtained from the dean of the medical school, University of Maryland, Baltimore.

## MICHIGAN

**Society News.**—Dr. Gordon E. Richards, Toronto, addressed a joint meeting of the Wayne County Medical Society with the Detroit Roentgen-Ray and Radium Society, May 3, on "Value of Roentgenology in the Diagnosis and Control of Treatment of Pulmonary Tuberculosis."——Chalmer J. Lyons, D.D.S., Ann Arbor, addressed the Washtenaw County Medical Society, May 10, on "Relation of the Mouth to Disease."——Dr. Egil T. Olsen, Detroit, was elected president of the Michigan Hospital Association, April 27.——Dr. Grover C. Penberthy, Detroit, was elected president of the Michigan Association of Industrial Physicians and Surgeons, April 29, and Dr. Howell L. Begle, Detroit, secretary.——Dr. Floyd H. Lashmet, Ann Arbor, addressed the Oakland County Medical Society, Pontiac, May 19, on "Water Balance Treatment of Edema."

**New X-Ray Unit.**—The new x-ray department of the University of Michigan Hospital was recently opened. T unit, which is said to be unexcelled in the country, has a novel plan of rooms and apparatus. From waiting rooms the patients are directed to private dressing rooms from which they pass to the proper department. The rapid development of films is made possible by a dark room, provided with dry air from which all moisture has been chilled out by refrigerating machinery. From the drying rack they may be taken directly to the physicians' offices, each of which has its own viewing apparatus, so that a report may be given in a fraction of the usual time needed. Memorializing Dr. Preston M. Hickey, for many years head of the department, *Science* states, is a staff library which will contain publications on roentgenology, given by Dr. Hickey's friends. The memorial bas-relief of Dr. Hickey, presented recently by the American Roentgen Ray Society, has been hung in the special conference room set aside for the members of the hospital staff who wish to review the examination of the patients with members of the roentgenology staff.

## MISSOURI

**Personal.**—Winterton C. Curtis, Ph.D., professor of zoology, University of Missouri, Columbia, will spend a year as visiting professor at Keio Gijiku University of Tokyo, Japan, under a grant from the Rockefeller Foundation. *Science* states that Dr. Curtis will maintain an office in the Keio School of Medicine, in a building erected by the Rockefeller Foundation. He will give instruction in the school and carry on research. ——Dr. Walter S. Hull, Faucett, was reappointed health officer of Buchanan County recently.

**Society News.**—Dr. George B. Arnold, Kansas City, was elected president of the Kansas City Urological Society recently.——Dr. Albert N. B. Lemoine was recently elected president of the Kansas City Society of Ophthalmology and Otolaryngology.——A joint meeting of the St. Louis dental and medical societies, May 10, was addressed, among others, by Arthur C. Engel, D.D.S., on "Oral Surgery from a Dental Standpoint"; Dr. Ralph A. Kinsella, "Dental Manifestations in Systemic Diseases," and O. W. Brandhorst, D.D.S., "Facial Development and the Care of the Teeth."——The St. Louis Medical Society was addressed, April 26, by Drs. James R. Nakada on "Tularemia—Three Cases with Remarkable Recovery in Two," and William K. McIntyre, "Precancerous Changes in the Rectum."——Speakers before the Nodaway County Medical Society in Maryville, May 13, were Drs. Benjamin Landis Elliott and Ralph E. Duncan, Kansas City, on "Encephalitis Lethargica" and "Modern Use of Oxygen as a Therapeutic Agent," respectively.——Dr. Percival Bailey, Chicago, addressed the Kansas City Academy of Medicine, May 20, on "Histological Structure and Prognosis of Gliomas of the Brain."

## NEW JERSEY

**Research Laboratory.**—Ground was recently broken for the erection of a research laboratory at the plant of Merck and Company, Inc., Rahway. A south wing will be devoted to carrying on pure or fundamental research, for which three laboratories will be provided. Another laboratory will be fitted for biochemical research with an adjoining incubator room containing a sterilizer, incubator and other necessary equipment. In a pharmacologic laboratory the physiologic action of various chemicals will be investigated. There will also be a laboratory for micro-analysis, a microbalance room, an ordinary balance room and an ice room. The north wing will contain a large chemical laboratory suitable for twelve chemists carrying on applied research and development work. The central section will contain, among other things, a library.

## NEW YORK

**Society News.**—The annual tumor clinic of the Memorial Hospital, Albany, was held, May 4, in collaboration with the New York state departments of health and education. Addresses were made by Drs. Lloyd F. Craver, New York, on "Leukemia, Hodgkin's Disease and Other Tumors of the Lymphatic System," and George T. Pack, New York, "Cancer—Its Cure and Prevention."

**Unlicensed Practitioner Sentenced.**—The state education department of the University of the State of New York reports the conviction of James Bockman in the Court of Special Sessions recently on a charge of practicing medicine without a license. He was sentenced to serve four months in the workhouse and in addition to pay a fine of $250 or in default of payment to spend sixty days additional in the workhouse. Bockman claimed to be a graduate of the Kansas City College of Medicine and Surgery and admitted that he had been licensed in Connecticut but that this license has been revoked because his schools were unqualified. He holds a license issued to him, May 10, 1922, on examination by the Arkansas Eclectic Board of Medical Examiners. Bockman appealed from his first conviction on this charge, but it was upheld by the supreme court and the case was remanded to the trial court for resentence, March 16, when a heavier sentence was imposed.

### New York City

**Dr. Ewing Appointed Director of Memorial Hospital.**—Dr. James Ewing, who recently resigned after thirty years as professor of pathology at Cornell University Medical College, has been appointed director of Memorial Hospital for the Treatment of Cancer and Allied Diseases in full charge of all its departments and activities, effective July 1. Dr. Ewing, a native of Pittsburgh, received his medical degree from Columbia University College of Physicians and Surgeons in 1891 and was instructor in clinical pathology at his alma mater for several years before becoming affiliated with Cornell. He has been director of cancer research at Memorial Hospital for a number of years and is the author of a book on cancer as well as many articles on pathology.

**Noise Abatement Commission.**—Announcement has been made of the dissolution of the Noise Abatement Commission, bringing to an end its three-year study of noise in New York. However, at the request of the city health commissioner and the police commissioner, the members of the commission have agreed to continue, as a body of private citizens, to assist the police and health departments in their work of helping to quiet the city. The final report of the commission will be published in the fall. It will outline the methods by which the commission believes a municipality may achieve reasonable quiet and will discuss experiments carried on by the commission since the publication of its first report in 1930. The Noise Abatement Commission was appointed in 1929 to define New York's noise problem, to ascertain its effect on the inhabitants, and to evolve methods for relief. The commission's preliminary report, published in 1930, dealt with the first two of these problems, while the final report will deal with the third. When the commission was organized, it was said to be the first official noise abatement commission (The Journal, Oct. 26, 1929, p. 1317).

**Society News.**—Drs. Russell S. Fowler and Emanuel D. Friedman addressed the Medical Society of the County of Kings, May 17, on "Gallbladder Disease—End-Results in a Study of One Thousand Cases" and "Experiences with Encephalography and Its Evaluation in Clinical Neurology," respectively.——Dr. John H. Garlock, Jr., addressed the New York Surgical Society, May 11, on "Free Full Thickness Graft."——Drs. Lewellys F. Barker, Baltimore, and Benjamin H. Archer addressed the Bronx County Medical Society, May 18, on private group clinics and evolution of group practice, respectively.——Dr. Henry L. Jaffe, among others, addressed the New York Pathological Society, May 26, on 'Factors Influencing Types of Bone Resorption."——Dr. George Baehr delivered an afternoon lecture before the Medical Society of the County of Queens, May 20, on treatment of diabetes.——A symposium on middle age was presented at the meeting of the Medical Society of the County of New York, May 27, with the following participants: Drs. Nellis B. Foster, Russell L. Cecil, Arthur M. Fishberg, Foster Kennedy and Robert T. Frank.

## OHIO

**Academy Adopts Industrial Code.**—A plan of procedure to be used by members of the Academy of Medicine of Cleveland desirous of making contact with industrial firms was approved, April 12, by the board of directors and the council. According to the plan, members of the academy before offering their services to an employer shall ascertain in writing through the executive office of the academy whether the firm desires the services of an industrial physician.

**Illegal Practitioners Prosecuted.**—The following is a list of illegal practitioners recently prosecuted, among others, by the state medical board:

C. M. Dyhre, unlicensed practitioner of medicine; found guilty of conducting an office without a certificate; fined $25 and costs.
Grant C. Pruner, charged with advertising; pleaded guilty; fined $200 and costs; suspended on promise to quit.
Glen Arnold, unlicensed chiropractor; found guilty of advertising and announcing himself as a practitioner without a certificate; fined $50 and costs.
Paul A. Hemple, charged with illegal practice of medicine; found guilty and fined $250 and costs.
D. A. Row, found guilty of practicing medicine illegally.

**Society News.**—The Mahoning County Medical Society was addressed, May 19, by Dr. Temple S. Fay, Philadelphia, on "Intracranial Pressure Problems Encountered in General Medicine."——The Academy of Medicine of Cincinnati was addressed, May 16, by Drs. Hiram B. Weiss and Harry L.

Claassen on "Hereditary Factors in Vascular Disease" and "A Newer Method in the Treatment of Chancroid," respectively.——Dr. Jonathan Forman, Columbus, addressed the Summit County Medical Society, May 10, on "Atopy in General Practice."——Dr. Irving S. Cutter, Chicago, will address the Montgomery County Medical Society, Dayton, June 3, on "The Story of Childbed Fever."

## OREGON

**Joyce Lecture.**—Dr. William Darrach, dean emeritus and professor of clinical surgery, Columbia University College of Physicians and Surgeons, New York, delivered the annual Joyce Lecture of the Portland Academy of Medicine, April 21, on "Colles' Fracture." The Portland City and County Medical Society attended the lecture in lieu of holding its regular meeting for April.

**Dr. Cannon Gives Jones Lectures.**—The eighth Noble Wiley Jones lectures at the University of Oregon Medical School were recently given by Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard University Medical School, Boston. The titles of his addresses were "The Fluid Matrix as a Means of Stabilizing the Organism" and "The Function of the Autonomic Nervous System in Controlling the Fluid Matrix."

## PENNSYLVANIA

**Hospital News.**—The unveiling of a portrait of Dr. William T. Sharpless, first physician at the Chester County Hospital, West Chester, was a feature of the institution's fortieth anniversary and founders' day celebration, May 12. Dr. U. Grant Gifford, Kennett Square, president of the medical staff, presented the portrait, which was a gift of the board of managers, the staff, the women's auxiliary and the nurses' alumnae association.

**Society News.**—Drs. Willis F. Manges, Philadelphia, and William W. G. Maclachlan, Pittsburgh, addressed the annual meeting of the eleventh councilor district of the Medical Society of the State of Pennsylvania, May 19, at the Nemacolin Country Club, near Washington.——At a meeting of the Allegheny County Medical Society, Pittsburgh, May 17, addresses were presented by Drs. Charles H. Henninger, on "Mental Hygiene and Industry"; Paul Titus, "Value of Clinical Research in a General Hospital"; Theodore O. Elterich, "Preventive Treatment of Measles—A Public Health Problem," and C. Leonard O'Connell, Ph.G., "Reciprocal Aspects of Medicine and Pharmacy."

## RHODE ISLAND

**Bill Enacted.**—H. 820, to require all hospitals, except state institutions, maternity hospitals or convalescent homes, to be licensed by the state public health commission, has become a law.

**License Revoked.**—The medical certificate of Dr. George Roy, Central Falls, was revoked by the Rhode Island State Public Health Commission, April 14, because of his having performed an illegal operation. Dr. Roy, who was convicted and sentenced in Worcester, Mass., served a prison term.

**Hospital Council Organized.**—A Council of Hospital Superintendents for Rhode Island was organized, March 18. According to *Modern Hospital*, the objects of the organization are cooperation among the administrators of hospitals in Rhode Island, promotion and coordination of their work, promotion of economy and efficiency in hospital management, and development of participating relationships with the organized medical profession, state and city authorities and unofficial agencies.

**Society News.**—The Providence Medical Association was addressed, May 2, by Drs. Eske H. Windsberg and Samuel Morein on "Thoracoplasty in the Treatment of Chronic Pulmonary Tuberculosis" and "Diaphragmatic Hernia: Symptomatology and Diagnosis," respectively.——A motion picture showing the results of gastro-enterostomy was shown at the meeting of the Newport County Medical Society, Newport, May 10.——A series of informal medical conferences was inaugurated by the division of university health at Brown University recently for Providence physicians. Dr. John S. Hodgson, Boston, was the guest in March, speaking on neurosurgical problems, and Dr. Charles S. Kubik, Boston, spoke at the April meeting on brain tumors and abscesses.

## SOUTH CAROLINA

**Bill Enacted.**—H. 1351, to create a board of chiropractic examiners and to regulate the practice of chiropractic, has become a law.

## TEXAS

**State Medical Election.**—Dr. A. A. Ross, Lockhart, was designated president-elect of the State Medical Association of Texas at its meeting in Waco, May 4-7. Dr. John H. Foster, Houston, assumed the presidency, and other officers elected were Drs. Andrew D. Nelson, San Saba; Herschel F. Connally, Waco, and Robert Y. Lacy, Pittsburg, all vice presidents; Holman Taylor and Khleber H. Beall, both of Fort Worth, secretary and treasurer, respectively, reelected. The 1933 meeting of the association will be in Fort Worth.

**Special Societies Elect.**—Officers of three special societies which met in conjunction with the State Medical Association of Texas in Waco, May 4-7, were elected at the closing sessions. Dr. John A. McIntosh, San Antonio, was elected president of the Texas Neurological Society, and Dr. Wilmer L. Allison, Fort Worth, secretary. Dr. Clark A. Wilcox, Wichita Falls, was named president-elect of the Texas Radiological Society, and Dr. Eugene V. Powell, Temple, secretary. Dr. Irwin E. Colgin, Waco, was elected president of the Texas Railway Surgeons' Association, and Dr. Ross B. Trigg, Fort Worth, secretary.

## WISCONSIN

**Society News.**—Dr. Vilray P. Blair, St. Louis, and George W. Wilson, D.D.S., addressed a joint meeting of the Medical Society of Milwaukee County and the Milwaukee County Dental Society, May 20, on "Surface Repairs for Both Function and Appearance" and "Medical-Dental Relations," respectively.——Dr. Leonard G. Rowntree, Rochester, Minn., made an address on "Water in Health and Disease" before the Milwaukee Academy of Medicine, May 17.——The radiologic section of the State Medical Society of Wisconsin held its spring meeting in Madison, May 27-28. Among speakers were Drs. Maximilian J. Hubeny, Chicago, on "The Radiologist and the Medical Profession"; Silvanus A. Morton, Milwaukee, "Radiological Diagnosis of Congenital Dislocation of the Hip," and Hans W. Hefke, Milwaukee, "Limitations of Intravenous Urography." A symposium on "Roentgen Diagnosis and Management of Bone Lesions" was presented by Madison radiologists.

## GENERAL

**American Urological Association.**—The twenty-ninth annual meeting of the American Urological Association will be held in Toronto, Ont., Canada, May 31-June 2, under the presidency of Dr. Alexander Randall, Philadelphia. Dr. Randall will give his presidential address at a meeting, June 1. At this session also the Ramon Guiteras Lecture will be delivered by Mr. Henry Wade, Edinburgh, Scotland, on "The Balanced Urinary Tract." Dry clinics will be held the first two days from 8 to 10 a. m., under the direction of the urologists of Toronto.

**Medical Bills in Congress.**—*Changes in Status:* H. R. 4743 has passed the House, providing federal subsidies to the several states to aid in rehabilitating persons disabled in industry or otherwise. The House Ways and Means Committee held hearings, May 19, on H. R. 11082, a bill to remove certain restrictions now imposed by law on the dissemination of articles and information for the prevention of conception. A similar bill in the Senate, S. 4436, was considered by a subcommittee of the Judiciary Committee, May 19 and 20. H. R. 10236, referred to as the tax bill, has been favorably reported to the Senate, with amendments. As passed by the House, it carried language which was interpreted as imposing a 10 per cent tax on eyeglasses and spectacles. The Senate Finance Committee, however, eliminated this language.

**Bulletin of the Health Organizations of League of Nations.**—In order to make the material developed through the Health Organizations of the League of Nations more widely known and more easily available, a quarterly bulletin has been established for general circulation. The first issue provides the resolutions of the Conference on Immunization Against Diphtheria, held in London in June, 1931; a discussion of medical education in England by Sir George Newman; a report on the milk supply of North American cities; another on tropical pneumonia; another on antirabies treatment, and one on floods in China. The material is authentic, well presented and in good English. The subscription price is to be $2 a year, single copies 50 cents. It may be obtained from the Publications Department of the League of Nations in Geneva, or through authorized agents, such as the World Peace Foundation, 40 Mount Vernon Street, Boston 9, Mass.

**Society News.**—At the recent annual meeting of the American Society for Experimental Pathology, Dr. Francis

Peyton Rous, New York, was elected president; Dr. Carl V. Weller, Ann Arbor, vice president, and Dr. C. Phillip Miller, Jr., Chicago, reelected secretary.——Among speakers at the annual meeting of the American Drug Manufacturers' Association, White Sulphur Springs, W. Va., in April, was Paul N. Leech, Ph.D., director, Chemical Laboratory, American Medical Association, Chicago, on "How Manufacturers Can Cooperate with the Council on Pharmacy and Chemistry of the American Medical Association."——Dr. Mary O'Malley, Washington, D. C., was made president-elect of the Medical Women's National Association at the annual meeting in New Orleans, May 9.——Dr. Curtice Rosser, Dallas, Texas, was elected president of the American Proctologic Society in Memphis, Tenn., May 7.——Dr. Arthur Dean Bevan, Chicago, was elected president of the American Surgical Association at its recent annual meeting in New Haven, Conn. The vice presidents are Drs. Frederick N. G. Starr, Toronto, and William F. Verdi, New Haven, and the secretary is Dr. Vernon C. David, Chicago, reelected.

**Pacific Northwest Medical Association.**—The tenth annual session of the Pacific Northwest Medical Association will be held in Spokane, Wash., June 27-29. The tentative program lists among the speakers Drs. Henry C. Bazett, Philadelphia, physiology; Samuel R. Cunningham, Oklahoma City, orthopedics and fractures; Harry Gideon Wells, Chicago, pathology; William J. Kerr, San Francisco, medicine; Philip H. Kreuscher, Chicago, orthopedics; Charles B. Wright, Minneapolis, medicine; Temple S. Fay, Philadelphia, neurosurgery; Henry E. Michelson, Minneapolis, skin and syphilis; Edgar L. Gilcreest, San Francisco, surgery; Fred W. Rankin, Rochester, Minn., surgery, and Richard T. Atkins, New York, otolaryngology. The subjects to be discussed will include circulation, methods of measurement and their clinical value; elbow injuries; adipose tissue; frequent mistakes in diagnosis of peripheral vascular disease; internal derangement of the knee joint; cerebral symptoms and manifestations throughout the field of medicine; diagnosis of cutaneous cancer; the common syndrome of rupture, dislocation and elongation of the tendon of the long head of the biceps; diagnosis and treatment of a typical hyperthyroidism, and intracranial complications of otitic origin, with special reference to the pathways of infection.

**Resolution on Standard Ventilating Code.**—The executive committee of the American Institute of Architects recently adopted a resolution setting forth the institute's opposition to any standard ventilating code until such time as an agreement between recognized authorities in the medical and engineering professions has been reached regarding minimum requirements for ventilation. It also opposes the promulgation or adoption of further codes, requirements, regulations or standards of ventilation until such agreement has been reached. In the resolution, attention is called to the tremendous annual expenditure for ventilating equipment, involving the health, welfare and comfort of the general public. The prevailing standards of practice in the ventilation of buildings are not supported by proved scientific facts, the resolution points out. It calls attention to the disagreement of competent hygienists and medical authorities with heating and ventilating engineers, on the basis of authentic physiologic data from reliable sources. The institute recommends the revision or repeal of present codes and regulations relating to the ventilation of buildings, wherever they are not supported by rational and authentic physiologic data acceptable to both the hygienist and the engineer. It favors the creation of a national movement to determine the factors to be considered in maintaining the health, comfort and safety of the occupants of buildings as affected by ventilation. These factors, when determined, would be used as the basis for a ventilating code of fundamental minimum standards generally applicable in all communities, the resolution further recommends. The resolution was adopted following the consideration of a similar one submitted by the Ohio State Association of Architects.

## CORRECTION

**State Board Statistics.**—In THE JOURNAL for April 23, page 1470, the statement was made that Georgia, Kansas, Minnesota, New Hampshire, Oklahoma and South Dakota offered the easiest examinations, since they have reported no failures in the last five years. It should have been emphasized that Minnesota has a Basic Science Board and that there have been no failures because the Basic Science Board in most instances sifts out candidates not able to pass. The Minnesota Board of Medical Examiners, therefore, deals with a selected group.

*(From Our Regular Correspondent)*

April 30, 1932.

### Drug Addiction in Egypt

At a meeting of the League of Nations Advisory Committee on Traffic in Opium, Russell Pasha, director of the Egyptian central narcotics intelligence bureau, estimated that 282,000 of the Egyptian male population of 3,137,000 were addicted to hashish, 93,000 to opium and 54,000 to diacetylmorphine. A large reduction in "white drug" addicts had been brought about in three years, partly by the greed of the traffickers, who had increased the adulteration in the retail trade up to an average of 85 per cent and partly by the general economic situation. The fellaheen could no longer produce their daily 25 cents for dope. In spite of her efforts, Egypt had not been able so far to save herself from the narcotic nuisance. Russell Pasha thought it was time that trafficking should be looked on as an international offense. Turkey was still providing the contraband diacetylmorphine. He was much impressed by the determination of high Turkish officials to clear Istanbul of its reputation for being the center of illicit traffic in diacetylmorphine. But this could be done only by closing all the private factories and the establishment of a government factory in the interior of the country. There were also gaps in Greek legislation affecting narcotics, but the authorities had recently drafted complete legislation. He also hoped that the French authorities in Syria would lose no time in closing the breach in their legislation, which fails to make possession an offense. He appealed to the Italian delegate to help put a stop to the long established system of smuggling diacetylmorphine by the personnel of Italian steamships. The antinarcotic police of the affected countries were working in close cooperation, and the coming year would prove uncomfortable for the big contrabrand organizations. They were looking for new markets in which they could pervert the population to narcotic addiction. Their eyes were now on the Far East.

### Anti-Cancer Education League

The British Empire Cancer Campaign has inaugurated a new movement in the form of the "Anti-Cancer Education League." At the opening meeting Dr. Malcolm Donaldson gave a lecture in which he appealed for consultation with the family physician periodically, especially for people over 40. Beyond question, cancer could be treated successfully if detected in an early stage. The main reason for failing to see a physician at this treatable stage was the common belief that if a swelling did not cause pain it could not be cancer. But the fact was that in many cases early cancer was painless and symptomless. It was impossible to teach the people symptoms; the only practicable method was to visit a physician twice a year, even though feeling quite well. Only thus could the alarming yearly incidence of 56,000 deaths be materially reduced. The Ministry of Health reported, in regard to cancer of the female breast, that, if it was attacked while still local, 80 per cent of the patients survived three or more years after treatment; whereas if treatment was delayed till after the formation of secondary growths, only 30 per cent or less survived this period. The records of the ministry showed that only half the patients with cancer sought advice and treatment at a curable stage. It was the policy of the league to have a branch in every town.

### Sir William Watson Cheyne

Sir William Watson Cheyne, well known for the part he played in the introduction of Lister's antiseptic method into England, has died in his eightieth year. Born in the Shetland Islands of seafaring stock, his fair hair suggested the blood of

Scandinavian invaders of those parts, as did his love of the sea. Educated at Edinburgh, he came under the influence of Lister and many years later, in delivering the Lister memorial lecture, he described his first lecture from the great man thus: "I became fascinated with the subject and could not help seeing the wonderful era that was dawning on surgery." Lister was struck with Cheyne's ability and appointed him his dresser. In 1875, Cheyne graduated with honors and proceeded to Vienna and Strasbourg to study. In 1877, when Lister accepted the invitation to join the staff of King's College Hospital, London, he stipulated that he should be allowed to bring from Edinburgh four assistants trained in his methods, which were then new to London. Of these the principal was Cheyne, whom he appointed his house surgeon. Later Cheyne attained the post of assistant surgeon to the hospital and became a leading surgeon and president of the Royal College of Surgeons. He was well known for his works, mainly on the antiseptic system, including "Antiseptic Surgery," "A Manual of Surgical Treatment" in seven volumes (jointly with F. F. Burghard) and "Tuberculous Diseases of Bones and Joints."

### Committee on Maxillofacial Injuries

A standing committee under the director general of the army medical service has been formed to investigate maxillofacial injuries. The committee includes leading dental surgeons and Sir Harold D. Gillies, whose work in the treatment of facial injuries sustained in the great war is so well known. The committee will make recommendations in regard to the provision of special facilities and equipment for these cases, the general method of treatment and the training of dental officers in the principles of preliminary treatment in the field.

### Vitamin D and the Teeth

The seventeenth annual report of the Medical Research Council contains further observations by Mrs. Mellanby to prove that "the health and beauty of the mouth" are directly dependent on an adequate supply of vitamin D in the diet, and that the state of the teeth of children affords a very sensitive test as to the adequacy of the diet. Large groups of children living in institutions under similar conditions received a specific addition to the standard diet and were regularly examined, and the progress of dental decay in the permanent teeth was recorded. A striking difference was found in the rate of increase of decay between groups receiving a ration of vitamin D in the form of cod liver oil or irradiated ergosterol and the controls who received other oils. In the former group the percentage of increase was 10; in the latter group, 46. It is noteworthy that the standard diet which all the children were receiving was believed by the medical and lay authorities concerned to be perfectly adequate for normal health and growth.

### The Medical Research Council and the Manufacture of Therapeutic Substances

The Medical Research Council regards it as its function not only to promote scientific discovery but also to facilitate the availability of the results in the interests of the medical profession and of the public. Much time and labor are often necessary before the yield of a new substance can be brought to the phase of large scale production. Cooperation between investigators and manufacturing firms has been promoted in various ways, of which one is the organization of the Therapeutic Trials Committee, which works in close cooperation with the Chemotherapy Committee, responsible for the experimental work on drugs and preparations submitted. Consultation with the Association of British Manufacturers has resulted in agreed conditions under which new substances may be submitted for clinical study. The council has assisted in the rapid development of the manufacturing of insulin in this country and has given assistance in the production of vitamin D, various organic extracts, and material for inoculation against distemper in dogs. On the other hand, the chief manufacturing firms are always ready to offer the results of their experience, to supply raw materials and to help in other ways.

### The Dissociate Diet

In previous communications, Mr. J. J. Rouzaud and Mr. G. Soula called attention to a new dietetic method, the results of which to date they discuss in the *Presse médicale*. This method, which they term the "dissociate diet," has today many advocates in France and it has been taken up also in foreign countries. Its essential principle consists in not prescribing nitrogenous foods and carbohydrates at the same meal but at different meals. Physiologically, these two groups of foods must necessarily figure in a normal diet, but each of them sets a different digestive task, and that task is accomplished better, and with less fatigue of the organs, when they have to deal with only one type of food at a time. That, at least, is the explanation proposed by Rouzaud and Soula. According to their experience, a meal consisting solely of nitrogenous foods or solely of carbohydrates causes less congestion of the vascular apparatus of the digestive tract than a complex meal, which is, of course, easily digested and causes no trouble to a normal person. But when the digestive functions are disordered, postprandial congestion appears, thus affecting the liver and the entire nutrition. The most remarkable results have been secured, by means of this diet, in glycosuria, but always proportionately to the degree of the disorder. Rouzaud and Soula have given this treatment in 320 cases. In the first series of 109 cases, characterized by a mild glycosuria of the alimentary type, with a week's glycemia fasting, the dissociate diet dispelled the glycosuria in 87 cases, brought improvement in 18 cases, and was ineffective in 4 cases. But it suffices to give just one meal in which the proteins and the carbohydrates are mixed to cause the glycosuria to reappear. In a second category of patients affected with permanent glycosuria, with a percentage of glycemia fasting ranging from 2 to 3 Gm., the results are still good; but the effects of the diet become less marked, the higher the glycemia is. When confirmed diabetes exists, with denutrition and acidosis, one can no longer count on a cure but only an amelioration in a third of the cases. It appears that then the pancreatic insufficiency becomes the predominant note and that the usual treatment with insulin is necessary. In a general way, the method is not indicated in pancreatic diabetes. But it gives good results in diabetic patients presenting gouty, plethoric and hypertensive manifestations, in diabetes with cirrhosis, and especially in former calculus patients who have alimentary glycosuria. The same diet gives good results in various manifestations other than diabetes; for example, in arthritism associated with hepatism: migraine, asthma, obesity, flatulent dyspepsia. This diet is furthermore readily accepted by patients, as it is simple to follow. It is sufficient to prescribe a liquid or fruit, without bread, for breakfast; a lunch consisting of meat, fish, eggs, green vegetables and fruits, without bread, and with a minimal allowance of fluids, and a vegetarian dinner with bread.

### Treatment of Tabetic Atrophy of the Optic Nerve

Dr. Abadie, French ophthalmologist, came forth recently from his retirement to present to the Academy of Medicine the remarkable results that he has secured for many years from his treatment for atrophy of the optic nerve, which, since Charcot, has been considered a manifestation of tabes. According to Abadie, that atrophy is caused by a continuous and progressive vasoconstriction of the central artery of the retina. This conception led him to devise a treatment that consists in applying, every other day, a subcutaneous injection of 2 mg.

of atropine and an intravenous injection of 0.01 Gm. of mercuric cyanide. All the patients to whom Abadie has applied this treatment found the progressive evolution of their atrophy checked, and all benefited from an increase in their visual acuity, the improvement being much greater if the disorder was not far advanced. He concludes that the hope is justified that, as a result of this medication rigorously applied, tabetic atrophy, heretofore incurable and the cause of much blindness, will no longer be a serious menace. In reporting these results to the academy, Abadie likewise called attention to the fact that the treatment does not begin to act until after a number of injections have been given, and that it is necessary to continue the treatment as long as one observes an improvement in visual acuity.

### The National Dental Congress

The dentists of France held in Paris, from April 6 to 13, an important scientific and professional session. Several foreign stomatologists took part in the meeting: Haber and Brill of Berlin, Watry and Charlier of Brussels, Fritz Schenk of Vienna, and others, under the chairmanship of Dr. Friteau. Professor Carnot delivered an address. Several practical demonstrations and an exhibit of equipment were held in the rooms of the Grand Palais. Army pigeons from Toul carried to the soldiers of the East wise suggestions as to the utility of dental hygiene. Numerous miniature canoes, bearers of message of the same import, were thrown into the Seine from the pont Alexandre III and left to the mercy of the waves in the hope that they might serve to evangelize the Normans. Automobiles circulated along the highways, within a radius of 30 miles from Paris, throwing out leaflets to the people and putting up posters in the villages. During the whole period, termed "dental hygiene week," lessons in dental hygiene were given to all the children in the schools, by their instructors, and all the radio stations broadcast special instructions to the public.

### The American Hospital at Neuilly

The board of managers of the American Hospital at Neuilly met recently to hear the financial report of its chairman, Mr. A. Kingsley Macomber, for the year 1931. Mr. Macomber stated that the year just passed had been for the hospital the most critical year since it was established. But, in spite of the critical situation, it had been possible to extend the activities of the hospital, partly through economy but more particularly as the result of a fund-raising campaign to which the public had responded generously, the gifts amounting to $300,000. The budgetary deficit for the year 1931 was more than $80,000, in spite of many retrenchments. That was due to the decrease in the number of paying patients and to the increase of patients of limited means, who received treatment free or at half rates. The chief problem at present is to increase the hospital's sources of revenue. With that object in view, the board of managers is considering the creation of specialized services, periodic medical consultations, prenatal consultations and consultations on child care, a dental clinic, a dispensary for diabetic patients, another for physical therapy, and the like. Dr. Edmund L. Gros was reelected president of the medical staff of the hospital. Drs. Thierry de Martel and George M. Converse were reelected vice presidents, and Dr. Bove was again chosen secretary.

### Death of Pierre Teissier

The death of Dr. Pierre Teissier is announced. Professor Teissier had been professor of clinical medicine at the Faculté de médecine de Paris since 1911; member of the university council, and member of the Academy of Medicine since 1918. He was a favorite pupil of Potain and carried out many researches on diseases of the blood, the spleen and the heart, on tuberculosis, and particularly on the action of roentgen rays in tuberculosis. In 1927, he had served as the president of the Congress of Medicine. He was Commander of the Legion of Honor.

### The German Surgical Congress

The German Surgical Congress was held, March 30 to April 2, at the headquarters of the Deutsche Gesellschaft für Chirurgie, in Berlin. In his address of welcome, Professor Voelcker of Halle protested against the recent tendency to split off from surgery partial fields and to make special branches out of them. While it is true that there are eminent specialists in the fields of lung, brain and stomach surgery, yet such a special field can never be made the basis for training; for surgical instruction presupposes that the whole operative art be taught and practiced. He emphasized that only through universal training were great achievements in surgery possible. The hundredth anniversary of the birth of one of the founders of the Gesellschaft, Franz König, surgeon of Berlin, gave the chairman an opportunity, in his memorial speech, to support this conception by citing a conspicuous case.

The congress managed to present 140 communications and numerous demonstrations during the four days' session. The question of limiting the mental pabulum is always discussed, but no solution is ever found. As a whole, the congress offered a good survey of the present status of surgery. This session dealt more with general medical problems than with questions pertaining to operative technic. Almost all new research seeks, through perfection of diagnostic aids and through the far-reaching use of new knowledge on the constitution, to secure the greatest possible safety to the individual operation. That was seen clearly on the first day in the discussion of liver disorders, which revolved about the problem of liver function and the relation of the liver to the general economy of the organism. The papers of the surgeon and the internist (Professors Henschen of Basel and Brugsch of Halle) supplemented each other. The strong desire of the surgeons that they receive gallbladder cases in an early stage while still easily operable may be essentially furthered, through these researches.

The next topic, "The Importance of the Borderline Problems of Surgery and Internal Medicine," was discussed by Professor Rehn of Freiburg. Rehn illustrated, by a case of suppurative inflammation of the pleura and by gallbladder disorders, how necessary collaboration of the internist and the surgeon is. In such borderline cases, one cannot say that either the internist or the surgeon has jurisdiction; otherwise there would be danger that sometimes an operation would be undertaken too early and another time too late. The one-sided point of view in such conditions, on the part either of a surgeon too eager to operate or of an internist who may believe that he can render aid with medicaments or by physical agents, may be equally harmful. The surgeon and the internist must work hand in hand, on the borderline of surgery and medicine, and apply all means of modern biology to find the most favorable moment for an intervention if needed. Such a situation arises frequently if one studies carefully the delicate acid-base equilibrium. In this way, both surgeon and internist will have a common basis for their mode of treatment. This double treatment of the subject brought out the fact that the surgeon is dependent on the research methods of the internist; for, in connection with anesthesia and the operation, dangers may arise when the damaged condition of the liver is not recognized in time. A damaged liver is not infrequently the cause for the unhappy outcome of operations. Professor Kirschner of Tübingen discussed spinal anesthesia, after the Bier method. Kirschner has applied his method with success in numerous cases. The operator draws off spinal fluid and then injects air with a specially constructed syringe and, following the air, the anesthetic. The anesthetic remains between the air layer and the fluid layer, as Kirschner showed in roentgenograms. By shifting the air and the fluid layers, the position of the anesthetic is so regulated that the portion of the body to be operated on is deprived of sensation.

On the second day, the chief topic was "Gangrene of the Extremities." Widely different causes may be responsible for the disease. By prompt treatment, amputation can be avoided in these cases. Removal of the nerves supplying the blood vessels, recommended by French authors, has not fulfilled expectations. German research has led to the discovery of so-called circulation hormones, to which possibly considerable therapeutic value attaches, although the question of their use is still a matter of debate. Their use sometimes enables one to avoid a threatened amputation. In many cases, however, amputation is the only way out.

The second speaker, the pathologist Ceelen of Bonn, began his address with a reference to Philoctetes, the story of whose gangrene is told in Sophocles tragedy. Ceelen discussed the three most important forms of gangrene: diabetic, senile and angioneurotic.

The spirited discussion that followed the papers showed that this subject is at present in the forefront of surgical interest. Here, too, was manifested a tendency to avoid mutilating operations on the extremities and to employ instead new methods of combating vascular diseases.

In the afternoon there was an inspection of the Latin Quarter and a drive about the city. The assembly hall was packed. Sauerbruch presented a paper on "Surgery of the Esophagus." He spent more time in presenting patients than in discussing the subject. A large number of men, women and children were introduced to demonstrate the surprising results of operative interventions on the esophagus, the bronchi, and the lungs. The young woman whose pericardium was opened last year because of an aneurysm that threatened her life appeared the picture of health. When the pericardium was opened, it was found unexpectedly that the aneurysm was connected with the heart by an opening, which necessitated quick action. To prevent her from bleeding to death, Sauerbruch held a finger in the opening, while his assistants sutured the heart wall.

Astonishing results were secured also in numerous other cases of suppuration, pulmonary gangrene, dilatations of the bronchi, and spasm or ulcers of the esophagus. Sauerbruch described how—frequently in several stages—the defects were repaired.

Nissen, Sauerbruch's physician-in-chief, reported his experiences in injuries of the lungs. Air, which sometimes collects in the mediastinum, is an immediate menace to life. The danger can often be promptly eliminated by puncture (aspiration).

The most impressive thing of this whole demonstration was the fact, as emphasized by Sauerbruch, that such operations on the thorax eliminate not only a local focus of disease but act, at the same time, on the general condition of the patient, and in some cases they are life saving.

Heile of Wiesbaden dealt with "Natural Therapeutic Processes." The tone of the discussion that followed showed plainly that among large groups of surgeons there is a tendency to conservative treatment. An operation is always only one of the factors to be considered, along with other therapeutic measures.

Among numerous other communications were the observations of Simon of Ludwigshafen on cancer-like tumors of the urinary bladder in aniline workers. They constitute a much feared industrial disease. It has been discovered that the irritant that causes the hyperplasia of the bladder wall is taken into the organism through ordinary respiration. By observing proper precautions in connection with respiration, the disease has been suppressed to a considerable extent. Until recently, physicians were powerless to combat these tumors.

On the last day, the congress reached a high level with its surgery of the extremities. This session proved conclusively that surgery still honors the ancient meaning of the term handicraft. Addresses on the surgery of cancer closed the session.

Läwen of Königsberg explained his treatment of chronic effusions of the knee joint, which consists in the formation of a fenestra into the joint capsule. Böhler of Vienna displayed enthusiasm in recommending that, in fractures of the vertebrae, the compressed vertebral bodies be adjusted as early as possible and the solidity of the spinal column be improved by gymnastic exercises. The psychologic factor—the belief of the patients in their recovery—is of the greatest importance. A moving picture and roentgenograms showed the good results effected in a number of persons who had suffered vertebral injuries.

Reschke of Greifswald spoke on suppuration of the bone marrow in the vicinity of the hip joint, operation on which he opposes in principle. Those who participated in the general discussion agreed with him, emphasizing that it requires more courage to resist the suggestion of an operation than it does to operate.

The statement of the chairman that the German surgeons were again taking part in the international surgical congresses was pleasing to the assembly. The hostility toward the surgeons of the Central Powers has been overcome. At the recent International Surgical Congress in Madrid, the representatives of the Deutsche Gesellschaft für Chirurgie were treated with every courtesy. Evidence of the change is the fact that Eiselsberg of Vienna was chosen president of the next International Surgical Congress.

## BELGIUM

*(From Our Regular Correspondent)*

March 21, 1932.

### Fogs in the Valley of the Meuse

In December, 1930, a thick fog spread over the valley of the Meuse between Huy and Liége for several days and caused many fatalities among the inhabitants. More than sixty persons succumbed and several hundred more were seriously discommoded. The symptoms were those of attacks of asthma, followed by a sudden cardiovascular insufficiency. Death often ensued within a few hours after the first attack. The treatment consisted of subcutaneous injections of epinephrine, which brought quick relief to many patients. Those who succumbed presented particles of soot in the alveoli of the lungs, derived from the factory chimneys of the surrounding region. Of the substances in the soot, chemical analysts incriminated only sulphurous anhydride and its products of oxidation, hydrofluoric acid, nitrous vapors, vapors of ammonia, and hydrochloric acid. The hydrofluoric acid does not appear to have been the principal factor of toxicity. Mr. Firket, in his report, expressed the view that nitrous vapors are capable of producing similar accidents to those observed. But nitrous vapors were not produced in sufficient quantity in the neighboring factories; nor were the vapors of ammonia and hydrochloric acid produced in large quantities. Sulphurous anhydride, arising from the combustion of coal, was no doubt the substance that was produced in the largest amount. Sulphurous anhydride, however, combines with water to produce sulphurous acid, and sulphuric acid is produced then by direct oxidation of sulphurous acid by the dissolved oxygen.

This explanation of the toxicity of the fog is the only one that is in complete accord with the medical, toxicologic, meteorological and chemical observations.

### Experiments on Transportation of Mosquitoes in Airplanes

The question has been raised whether mosquitoes may be transported by airplanes. Experiments have been made in the Belgian Congo, along the routes from Leopoldville to Boma, Elisabethville, Coquilhatville and Stanleyville. In only four cases were mosquitoes found on the arrival of the airplane

Mosquitoes were transported in small boxes. They were still living when the airplane had risen to about an altitude of 1,000 meters, and were dead when an altitude of from 1,700 to 2,000 meters had been reached. But these experiments must be repeated with greater precautions. Anopheles are sent regularly to England from Italy, Africa and America, 30 per cent arriving alive if the cages are well protected and proper food provided.

### Unauthorized Practice of Medicine by Nurses

In order to stop the increasing number of abuses, the Belgian medical federation has again called the attention of the public authorities and of the mutual life insurance companies to the practice of medicine by nurses and visiting nurses, urging them to limit strictly the interventions of nurses to their regularly assigned duties. It has likewise sent a request to the professors in the training schools for nurses and visiting nurses that they impress on their pupils that under no circumstances have they the right to perform an act of medical aid without express authorization—applicable only to the particular case in question—of the attending physician. The Belgian medical federation has requested, in an article in the *Bulletin Officiel*, that the professors, surgeons, physicians and the authorized midwives in the hospitals, clinics and maternities seek in their operations the assistance of physicians and refrain from extending the rôle of the attending nurses and the visiting nurses.

### The Brachet Memorial

The executive committee of the Albert Brachet commemoration, under the chairmanship of Professor Crismer, invited the subscribers and a number of dignitaries to convene at the Anatomic Institute to dedicate the medallion of the deceased scientist, which is the work of the sculptor De Vreese. In addition to the erection of the memorial, the funds collected gave a surplus of 100,000 francs, the interest on which will be used to create a biennial international prize in embryology, which will be awarded by the Royal Academy of Medicine of Belgium, under the name of the Brachet prize. Mr. Marcq, vice president of the administrative council of the university, thanked the organization committee for the gift of the memorial. He referred to Albert Brachet's life of sacrificing toil and his great influence over the students, which he attributed to a love of truth, justice and beauty. Albert Brachet was rector of the university for three years, which administration showed his fine qualities as an organizer and the spirit of prompt and just decision that animated him. Following the address, the guests went to the atrium of the institute, where the beautiful medallion, which represented Brachet at work, was unveiled by Mr. Crismer.

### The Belgian Medical Federation

Within the Fédération médicale belge, a Comité d'études de prophylaxie sociale has been created, the purpose of which is: (*a*) to study the practical means of coordinating the various decisions of the legislative, administrative and private organizations having to do with the protection of the public health; (*b*) to present and to defend in this field the suggestions of the medical profession and to transmit them to the public authorities or other competent authorities, and (*c*) to harmonize the practice of medicine and the interests of the physician, while assuring the protection of the public health.

This committee is under the direction of an official body composed of a president, two vice presidents, a general secretary and an associate secretary, appointed by the executive committee of the Fédération médicale belge, with the approval of the members of the Comité d'études de prophylaxie.

At least one of the five members of the body of officers will be a member of the executive committee of the Fédération médicale belge. Honorary members may be appointed at the suggestion of the Comité d'études de prophylaxie sociale. The Comité d'études de prophylaxie sociale will be composed of regular members and of associate members. Only the former have the voting privilege. All the members of the comité are approved by the executive committee of the Fédération médicales belge at the suggestion of the officers of the Bureau d'études de prophylaxie sociale. The members are physicians delegated by scientific societies, by official or private organizations engaged in medicosocial activities. The isolated physicians will be represented by the delegates of the Fédération médicale belge. All the members of the comité must belong to the Fédération médicale belge. The body of officers has, however, the right to engage any competent person to act as consultant with reference to the work of the committee. The studies of the Comité d'études de prophylaxie sociale are transmitted by the body of officers to the executive committee of the Fédération médicale belge, which may submit them to the general assembly or which may decide what disposition to make of them and notify the body of officers of the Comité d'études de prophylaxie sociale of its conclusions.

### Gustave Dryepondt, an Example of Civic Courage

The *Scalpel* of Jan. 9, 1932, contains an appreciation of Gustave Dryepondt, a beautiful and noble figure in the field of medicine that has passed from the scene. More than forty years ago, he braved with calmness the dangers of Africa, which then was so inhospitable. Today he has fallen, suddenly stricken in the midst of his activities. Dryepondt was a great patriot, a great colonizer and a man gifted with the noblest heart qualities. In 1890, on leaving the university, the young army physician, responding to an appeal of Leopold II, left his native land for the conquest of the "dark continent"—not sword in hand but as a disciple of Aesculapius, bringing to the unhappy people of central Africa the blessings of science. Dryepondt was a natural pioneer and trail blazer, as is shown by his long colonial career. At a time when life in Africa lacked the security of today, he emigrated with his family, giving thus to his compatriots a fine example of civic courage. He was the founder of the Société belge d'études coloniales, was a member of the Institut international colonial, and after the war was appointed colonial counselor by the king. After emerging from the great conflict, he organized the Journées coloniales, which contributed greatly to the interest in the colonies, in Belgium.

## BUENOS AIRES

*(From Our Regular Correspondent)*

Feb. 28, 1932.

### A New Medical Curriculum Adopted

The Faculty of Medicine of the University of Buenos Aires adopted a new medical curriculum and by-laws, which became effective March 16. The regulations express the advisability to restrict the number of students in the first and second years of medicine, as much and as soon as possible, so that only those well fitted may be selected. At present the first and second years are made up by groups of 600 or 800 students, not all of them well fitted, as proved by the fact that during the entire period of medical studies some students fail even ten or more times in a given subject. Some of them have been attending the school for the past twelve or fifteen years and have not as yet graduated. The examinations for admission to the study of medicine imposed on candidates have consisted heretofore of a written test on biology and zoology, three oral tests (in different days) in botany, physics and chemistry, and a test by which the student should prove his ability to translate from French. About 40 per cent of the candidates pass the examination. According to the new regulations, the examination for admission will consist of the same tests included in the examinations as heretofore, with the exception that there will be two oral tests instead of three, and in the translation test the student should prove his ability to translate from two foreign languages (either English and German or French and Italian). Henceforth, the number of years of medical study, which is now six, will be increased to seven, as it was in 1918. From the records of the school, it has been found that only 30 per cent of the students are able to finish the entire course of medical studies in six years; 15 per cent finish them in seven years and 55 per cent attend the school more than seven years in order to graduate. The new curriculum annuls semestral periods, each of which, heretofore, has had practically three and a half months of study. The periods will consist of the entire year of study. The July promotion examinations also are annulled, only the December and March examinations being continued in effect. The studies for the entire year will represent a complete unit. The program will be as follows: first year, histology, embryology and anatomy; second year, topographic and descriptive anatomy, physiology, biochemistry and biophysics; third year, physiology and biochemistry, pathologic anatomy, microbiology and parasitology; fourth year, symptomatology (classes every morning), surgery, pharmacology and therapeutics, toxicology, roentgenology and physical therapy; fifth year, medical and surgical pathology, otorhinolaryngology, ophthalmology and dermatosyphilography; sixth year, clinical work on gynecologic, urologic, psychiatric, neurologic, infectious, surgical and clinical cases; seventh year, clinical work on pediatric, obstetric, surgical, and clinical cases, orthopedics, legal medicine and hygiene. During the first three years the work of the student should cover attendance and work done in the amphitheater and laboratories; in the fourth year he must attend the clinics and the courses of symptomatology, and during the last three years he must devote regularly a certain number of hours to practical work in the hospital, either as an extern or as an intern.

### The Problem of Care of the Insane

Dr. G. Bosch, director of the Hospicio de las Mercedes of Buenos Aires, recently published an article embodying projects for the care of the insane. The census of 1869 showed that there were 4.3 mental defectives per thousand of population. The census of 1895 showed that in the entire group of mental defectives the rate among foreigners was twice that among Argentine persons. At present there are about 14,000 insane patients in the asylums of Argentina; that is, 1.26 per thousand of the population. These figures do not include, of course, psychiatric patients who receive attendance in their own homes, and they number perhaps still more than those in the asylums. There are no reliable statistics on the subject, but it may be estimated, on a reasonable basis, that the number of insane patients in Argentina varies between 24,000 and 43,000, which should be distributed among the seven large hospitals and ten sanatoriums that constitute the entire number of psychiatric centers in Argentina. The members of the Comisión de Asilos y Hospitales Regionales of Argentina are acting to provide the several regions of the country with the necessary psychiatric institutions. A large neuropsychiatric colony with an asylum, in which psychiatric patients of the northern region of Argentina will be taken care of, is under construction on the ranch of Linares, Lerma, province of Salta, where the board of directors of the commission recently acquired a large tract for that purpose. Plans are being made to open psychiatric consultation centers as well as to increase the number of hospitals and dispensaries for the care of patients with mental disease in every province of Argentina.

### Personal Items

Drs. M. Susini and R. Vaccarezza have been appointed president and secretary, respectively, of the National Department of Hygiene of Buenos Aires.

Dr. A. Pirovano has been appointed director of Public Health of Argentina.

### Deaths

Dr. A. Gandolfo, professor emeritus and honorary academician and former regular professor of surgical clinics at the Faculty of Medicine of the University of Buenos Aires, has died.

## Marriages

Tilden Iver Moe, Assistant Surgeon, Lieutenant (j. g.), U. S. Navy, to Miss Dorothy Mae White of Springfield, Ill., in Washington, D. C., May 11.

John Frampton Wyman, Aiken, S. C., to Miss Bonnie Anne Atkinson of Chicago, May 18.

Arthur Nelson Berry, Boston, to Miss Dorothea Marie Keough, recently.

Robert H. Rathbone to Miss Rowena Thom, both of Los Angeles, April 6.

## Deaths

**James Walter Heustis,** Dubuque, Iowa; Harvard University Medical School, Boston, 1884; past president of the Dubuque County Medical Society; served during the World War; formerly on the staffs of the Episcopal Eye and Ear Hospital and the Freedmen's Hospital, Washington, D. C., the Los Angeles County Hospital and the White Memorial Hospital, Los Angeles; aged 69; died, April 9, of coronary thrombosis.

**Bert Leander Eiker** ⊕ Leon, Iowa; Rush Medical College, Chicago, 1896; member of the House of Delegates of the American Medical Association, 1922, 1924 and 1928; fellow of the American College of Surgeons; president of the Iowa State Medical Society; formerly member of the state board of health and state legislature; aged 60; died, May 6, in a hospital at Sioux City, of pneumonia.

**Percy Bernard Davidson** ⊕ Boston; Johns Hopkins University School of Medicine, Baltimore, 1921; member of the New England Roentgen Ray Society; formerly instructor of pathology, University of Wisconsin Medical School, Madison; on the staff of the Beth Israel Hospital; aged 36; died, April 29, in the Boston City Hospital, following an operation.

**George W. McCoy** ⊕ Los Angeles; Miami Medical College, Cincinnati, 1904; member of the Pacific Coast Oto-Ophthalmological Society and fellow of the American College of Surgeons; senior ophthalmic surgeon to the Los Angeles County Hospital and on the senior surgical staff of the California Hospital; aged 61; died, April 21.

**Stephen Olin Watkins,** Minneapolis; University of the City of New York Medical Department, 1880; formerly superintendent of the Wyoming Tuberculosis Sanatorium, Basin; aged 81; died, April 11, at the Minnesota Masonic Home, of arteriosclerosis, cerebral hemorrhage and chronic myocarditis.

**S. Anson Hill,** San Francisco; Hahnemann Medical College and Hospital of Philadelphia, 1910; formerly clinical professor of applied homeopathic therapy, University of California Medical School; on the staff of the Southern Pacific Hospital; aged 44; died, April 10, of chronic interstitial nephritis.

**Frank Joseph Powers** ⊕ Baltimore; Baltimore University School of Medicine, 1898; served during the World War; medical superintendent of the Baltimore City Jail; aged 59; died, April 29, in the Mount Alto Hospital, Washington, D. C., of brain tumor.

**Joseph Harry Oppenheim,** New York; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1930; aged 30; intern, Beth Israel Hospital, where he died, March 7, of coronary thrombosis and diabetes mellitus.

**Ashley W. Ogle,** Sevierville, Tenn.; University of the South Medical Department, Sewanee, 1903; member of the Tennessee State Medical Association; past president of the Sevier County Medical Society; aged 51; died, March 31, of pneumonia.

**Jacob Long Sowers** ⊕ Lexington, N. C.; University of Maryland School of Medicine, Baltimore, 1921; past president of the Davidson County Medical Society; for two years county coroner; aged 38; was instantly killed, May 1, in an automobile collision.

**Edward Birtrum Cooper,** Sunbury, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1893; served during the World War; for many years on the staff of the Mary M. Packer Hospital; aged 61; died, March 17.

**J. N. Blume** ⊕ Arcadia, La.; Memphis (Tenn.) Hospital Medical College, 1903; aged 58; died, April 27, in a hospital at Shreveport, of injuries received when the automobile in which he was driving was struck by a train.

**Clarence Ray Essex,** Galesburg, Ill.; St. Louis College of Physicians and Surgeons, 1905; member of the Illinois State Medical Society; aged 50; on the staff of St. Mary's Hospital, where he died, April 22, of heart disease.

**Frank Pattison Werner** ⊕ Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1916; served during the World War; on the staff of the Reading Hospital; aged 41; died, April 4, of appendicitis.

**W. J. Houston, Jr.,** Decatur, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; aged 67; died, April 15, of acute infectious cholangeitis with subhepatic abscess and complete common duct obstruction.

**Harry Judge Craycroft** ⊕ Fresno, Calif.; Cooper Medical College, San Francisco, 1904; fellow of the American College of Surgeons; on the staff of the Fresno County Hospital; aged 54; died, March 18, of influenza.

**Menno H. Hostetler,** Wichita, Kan.; Starling-Ohio Medical College, Columbus, 1911; member of the Kansas Medical Society; county health officer; aged 50; died, April 10, in a hotel at Topeka, of angina pectoris.

**John Vincent O'Connor,** St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; aged 64; died, April 5, in St. Joseph's Hospital, of encephalomalacia and arteriosclerosis.

**Omar Joseph Massey,** Wheeling, W. Va.; Ohio State University College of Medicine, Columbus, 1931; intern, Wheeling Hospital; aged 38; died, April 20, of injuries received in an automobile accident.

**Louis J. Wolfort,** St. Louis; Missouri Medical College, St. Louis, 1895; member of the Missouri State Medical Association; aged 59; died, April 18, in the Josephine Hospital, of streptococcus cellulitis.

**John Walter Lambert,** Tangipahoa, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1887; for many years mayor of Tangipahoa; aged 70; died, March 28, of uremia and nephritis.

**Abraham Blumenfeld,** Boston; Tufts College Medical School, Boston, 1929; member of the Massachusetts Medical Society; aged 26; died, January 27, in the Beth Israel Hospital, of renal calculus.

**James Ralph Higgins** ⊕ Gillespie, Ill.; St. Louis University School of Medicine, 1913; served during the World War; aged 45; died, April 18, at the St. Francis Hospital, Litchfield, of heart disease.

**James McIlwain,** Okawville, Ill.; University of the City of New York Medical Department, 1868; member of the Illinois State Medical Society; aged 88; died, April 20, of influenza and arteriosclerosis.

**James W. Beck,** Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1881; formerly coroner of Polk County; aged 74; died, April 24, of coronary thrombosis and arteriosclerosis.

**Edward Ralph Cotham** ⊕ Monticello, Ark.; Jefferson Medical College of Philadelphia, 1903; served during the World War; aged 51; died, April 30, of arteriosclerosis and coronary occlusion.

**Peter Thomas Burns** ⊕ Chicago; Northwestern University Medical School, Chicago, 1891; for many years assistant professor of anatomy at his alma mater; aged 67; died, May 10, of myocarditis.

**William Oscar Spencer,** Multnomah, Ore.; Cooper Medical College, San Francisco, 1897; member of the Oregon State Medical Society; aged 65; died, February 25, of progressive muscular atrophy.

**Herbert Lee McKown,** Tunkhannock, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1894; member of the Medical Society of the State of Pennsylvania; aged 61; died, February 4.

**Albert H. Hattan,** Peru, Ill.; American Medical College, St. Louis, 1877; Chicago Homeopathic Medical College, 1893; aged 74; died, April 26, in Cadiz, Ohio, of heart disease and arteriosclerosis.

**Albert Leonard Miller** ⊕ Marysville, Calif.; Rush Medical College, Chicago, 1896; aged 60; on the staff of the Rideout Memorial Hospital, where he died, March 22, of coronary thrombosis.

**William J. J. Paris,** Rosiclare, Ill.; University of Tennessee Medical Department, Nashville, 1882; member of the Illinois State Medical Society; aged 78; died, March 21, of pneumonia.

**Allen Lowery,** Blackwell, Okla.; University of Louisv (Ky.) School of Medicine, 1891; aged 71; died, April 24, cerebral hemorrhage, following an operation for intesti obstruction.

**Clarence Eugene Applegate,** Long Beach, Calif.; Ru Medical College, Chicago, 1927; aged 33; died in April at local hospital of a skull fracture received in an automob accident.

**John McK. Wyatt,** Madison, Wis.; University of Nas ville (Tenn.) Medical Department, 1878; aged 83; died, Ap 11, in the Madison General Hospital, of bronchopneumon

**James McPherson Templeton** ⊕ Cary, N. C.; Baltimo Medical College, 1882; served during the World War; ag 76; died, May 1, in a hospital at Raleigh, of heart disease.

**Neil Kittredge Forhan,** Presque Isle, Maine; Tufts Co lege Medical School, Boston, 1912; aged 45; died, January 1 in the Boston City Hospital, of dilatation of the heart.

**Leslie Lenton Blair,** Denver, Colo.; Atlanta (Ga.) Colleg of Physicians and Surgeons, 1911; served during the Worl War; aged 43; died, April 13, of miliary tuberculosis.

**Benjamin Lee Jeter,** Millington, Tenn.; Memphis Hospital Medical College, 1893; aged 59; died, April 23, in th Baptist Hospital, Memphis, of cerebral hemorrhage.

**Richard Fricke,** Calistoga, Calif.; Baltimore Universit School of Medicine, 1891; aged 75; died, March 8, in Sa Francisco, of diabetes mellitus and arteriosclerosis.

**Charles Smith Bumstead,** New York; Albany Medica College, 1889; member of the Medical Society of the State o New York; aged 72; died, April 4, of myocarditis.

**Edward Newby Wheeler,** Decatur, Ill.; Rush Medical College, Chicago, 1878; Civil War veteran; aged 86; died, March 10, in St. Mary's Hospital, of pneumonia.

**George Henry Sherman** ⊕ Detroit; Chicago Medical College, 1883; aged 74; died, April 19, in a hospital at Melbourne, Fla., following an operation for appendicitis.

**Domenico Saladino** ⊕ Brooklyn; Eclectic Medical College of the City of New York, 1887; aged 69; died, April 23, of lobar pneumonia and chronic myocarditis.

**Mary D. Gibbons,** Oak Park, Ill.; Hahnemann Medical College and Hospital, Chicago, 1888; aged 81; died, April 21, of coronary sclerosis and nephrolithiasis.

**Michael Lewis Landman** ⊕ New York; Miami Medical College, Cincinnati, 1905; aged 48; died, April 15, of chronic interstitial nephritis and arteriosclerosis.

**Maurice W. Deming,** Newark, Ohio; Medico-Chirurgical College of Philadelphia, 1899; aged 69; died, April 21, of cerebral hemorrhage and influenza.

**Wesley Wilson Duncan,** Sorento, Ill.; American Medical College, St. Louis, 1878; Civil War veteran; aged 91; died, April 12, of acute bronchitis.

**Augustus Alison Gerlach** ⊕ Oakland, Calif.; University of California Medical School, San Francisco, 1929; aged 33; died, March 15, of influenza.

**Charles Travis Drennen** ⊕ Hot Springs National Park, Ark.; Rush Medical College, Chicago, 1885; aged 68; died, April 26, of heart disease.

**Charles Bolton Brock,** Richmond, Va.; Medical College of Virginia, Richmond, 1894; aged 61; died, April 11, of a self-inflicted bullet wound.

**Oscar William Stark,** Cincinnati; College of Physicians and Surgeons in the City of New York, 1887; aged 67; died, April 19, of heart disease.

**Marion Hendrickson,** Johnston City, Ill.; St. Louis College of Physicians and Surgeons, 1897; aged 61; died suddenly, April 25, of heart disease.

**La Rose Rancour** ⊕ New York; Albany (N. Y.) Medical College, 1892; aged 63; died suddenly, February 12, of a self inflicted bullet wound.

**David S. Ramseur,** Blacksburg, S. C.; Medical College of South Carolina, Charleston, 1879; aged 80; died, April 14, of cerebral hemorrhage.

**Frithjof A. Nordbye,** Camrose, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1908; aged 51; died in March.

**Joseph E. Huffman,** Santa Rosa, Calif.; Dunham Medical College, Chicago, 1897; aged 79; died, March 23, of hemiplegia and pneumonia.

**Norman A. Thomas,** Oil City, Pa.; Jefferson Medical College of Philadelphia, 1896; aged 63; died, April 11, of pneumonia.

## AN APHRODISIAC FRAUD

### Robert L. Teycer Mail-Order Fake Debarred from the Mails

On April 2, 1932, the Postmaster General, acting on the recommendation of Judge Horace J. Donnelly, Solicitor for the Post Office Department, issued a fraud order against Dr. Teycer, Dr. B. L. Teycer, Progressive Chemical Association, Teycer Mail Order Company, all of Chicago, and their officers and agents as such. Judge Donnelly in his memorandum to the Postmaster General reported, in effect, that the facts were as follows:

Robert L. Teycer, who is not a physician, had advertised in the matrimonial magazine, *King Cupid*, as follows:

> EXTRA DOUBLE STRENGTH VIGORENE
>
> Amazing Vim, Vigor, Staying power, Endurance. Master Medicine. Stimulates spinal genital center, recharges system at same time. No disappointments. $1.50. 2 boxes $2.50. Dr. Teycer, Box 1275KC. Chicago. Circular free

Those that answered the advertisement received circular matter from Teycer, in which it was stated that "after years of research work, chemical and physical tests, Dr. B. L. Teycer, Ph.C., one of the world's greatest chemists, has discovered one of the main causes of lost nature, lost manhood, poor endurance and staying power, and low sexual power." There was much more of the same sort. The alleged aphrodisiac which Robert L. Teycer sold had, according to the federal report, the following formula:

| | |
|---|---|
| Reduced Iron | ½ grain (or ¼ grain) |
| Quinine Sulphate | ¼ grain |
| Pulv. Capsicum | 1/20 grain |
| Strychnine Sulphate | 1/30 grain |
| Arsenic Trioxide | 1/60 grain |
| Formin | 1 grain |
| Buchu | 1 grain |
| *Zinc Phosphide* | 1/10 grain |
| Aloin | ¼ grain |
| Ergotin (Bonjean) | ¼ grain |
| Metagen ABC VITAMINS (Parke, Davis & Co.) | 3 grains |

The government brought out at the hearing that the claims made for Vigorene were false and fraudulent and that the stuff would not restore "lost manhood" to impotent old men, as represented. It was brought out, too, that the preparation did not contain significant quantities of the vitamins A, B or C, while some of the various drugs included in the preparation might easily have a deleterious effect on certain persons by causing or aggravating digestive disorders.

Teycer, according to the report, formerly operated a small drug store in Chicago, which was recently taken over by creditors. Instead of having "spent thousand of dollars making physical and chemical tests," as claimed, it was brought out at the hearing that Teycer simply selected some drugs which he found listed in a manual and incorporated them in the formula. As a result, Judge Donnelly declared that the scheme was one for obtaining money through the mails by means of false and fraudulent pretenses and recommended the issuance of a fraud order.

## MISBRANDED "PATENT MEDICINES"

### Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[*Editorial Note.*—The Food and Drug Administration of the U. S. Department of Agriculture publishes, in bulletins issued at frequent intervals, reports on "patent medicines" whose sale has been found to violate the national Food and Drugs Act. Unfortunately, this information is buried, so far as the general public is concerned. For that reason, THE JOURNAL has, ever since the Food and Drugs Act has been in existence, published abstracts of these notices and, later, reprinted the material in book and pamphlet form, for the information of the profession and the public. In the past, these abstracts have been sufficiently detailed to occupy an amount of space in THE JOURNAL that is out of proportion to their importance. Commencing with the present group, we are presenting such abstracts in the briefest possible form. First is given the name of the product with the name of the manufacturer, shipper, or consigner. Following this is the composition, as shown by the analyses made by the federal chemists; then comes a brief statement of the type of "patent medicine," unless the name of the product is self-explanatory; *finally, there is given the reason for the charge* of misbranding: Fraudulent therapeutic claims or false claims for composition or origin. It is to be borne in mind that the dates of issuance of the Notices of Judgment here abstracted may be several months later than the date of seizure of the product.]

**Pyo-Rem.**—Pyo-Rem Chemical Company, Inc., Los Angeles, Cal. Composition: Zinc chloride, potassium chlorate, with traces of boric acid, chloroform, and formaldehyde, colored red. For pyorrhea, etc. Fraudulent therapeutic claims.—[*N. J. 17602; April, 1931.*]

**Ware's Black Powder.**—W. S. Kirby Company, Dallas, Texas. Composition: Charcoal, bismuth subsalicylate and an iron compound. For stomach and bowel trouble. Fraudulent therapeutic claims.—[*N. J. 17608; April, 1931.*]

**Fansler's Kidney, Bladder and Rheumatism Medicine.**—Fansler Manufacturing Company, Marion, Ind. Composition: Copaiba and cubeb oleoresins, sandalwood oil, potassium chloride, potassium acetate, extracts of plant drugs, sugar, and 11.5 per cent alcohol. Alcohol content wrongly declared; fraudulent therapeutic claims.—[*N. J. 17612; April, 1931.*]

**Merle's Epsom Salt Tablets.**—Devore Manufacturing Company, Columbus, Ohio. Composition: Phenolphthalein, podophyllum, aloes, and epsom salt. False claims for composition.—[*N. J. 17623; April, 1931.*]

**Bronchuline.**—International Laboratories, Rochester, N. Y. Composition: An emulsion containing mineral oil, sodium and calcium glycerophosphates, and creosote flavored with wintergreen. A "cough cure." Fraudulent therapeutic claims.—[*N. J. 17624; April, 1931.*]

**Tonic Force.**—Zarpas Laboratories, Monessen, Pa. Composition: Sulphur, ground plant material, including aloes, iron oxide, cinchona alkaloids, a trace of arsenic, ginger, and malt syrup. Alleged blood purifier. Fraudulent therapeutic claims. —[*N. J. 17626; April, 1931.*]

**Mal-A-Tol.**—First Texas Chemical Manufacturing Company, Dallas, Texas. Composition: Quinine sulphate, drug extracts including a laxative, sodium benzoate, and arsenic and iron compounds. For chills, fever and malaria. Fraudulent therapeutic claims.—[*N. J. 17628; April, 1931.*]

**Alertox.**—Alertox, Inc., Atlanta, Ga. Composition: Epsom salt, sodium phosphate, and water. General cure-all. Fraudulent therapeutic claims.—[*N. J. 17629; April, 1931.*]

**Vapo Ply.**—Hoyt Bros., Inc., Newark, N. J. Composition: An ointment with a petrolatum base, containing oils of camphor, menthol, eucalyptol, thymol and wintergreen. An "asthma cure." Fraudulent therapeutic claims.—[*N. J. 17630; April, 1931.*]

**Hoyt's Cold Tablets.**—Hoyt Bros., Inc., Newark, N. J. Composition: Acetanilid, quinine sulphate, aloin, red pepper and camphor. Fraudulent therapeutic claims.—[*N. J. 17630; April, 1931.*]

**Hoyt's Catarrhal Jelly.**—Hoyt Bros., Inc., Newark, N. J. Composition: Petrolatum, camphor, menthol and eucalyptus oil. Fraudulent therapeutic claims.—[*N. J. 17630; April, 1931.*]

**Fenner's St. Vitus Dance Medicine.**—S. C. Wells and Company, LeRoy, N. Y. Composition: Compounds of arsenic and potassium, with extracts of plant drugs, volatile oils, and alcohol. Fraudulent therapeutic claims.—[*N. J. 17631; April, 1931.*]

**Potaska.**—F. M. Pease and Son, Lee, Mass. Composition: An ammonium compound, guaiac resin, potassium chlorate, lemon and lavender oils, sugar, alcohol, and water. For sore throat, bronchitis, etc. Fraudulent therapeutic claims.—[*N. J. 17632; April, 1931.*]

**Clarence Ray Essex,** Galesburg, Ill.; St. Louis College of Physicians and Surgeons, 1905; member of the Illinois State Medical Society; aged 50; on the staff of St. Mary's Hospital, where he died, April 22, of heart disease.

**Frank Pattison Werner** ⊕ Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1916; served during the World War; on the staff of the Reading Hospital; aged 41; died, April 4, of appendicitis.

**W. J. Houston, Jr.,** Decatur, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; aged 67; died, April 15, of acute infectious cholangeitis with subhepatic abscess and complete common duct obstruction.

**Harry Judge Craycroft** ⊕ Fresno, Calif.; Cooper Medical College, San Francisco, 1904; fellow of the American College of Surgeons; on the staff of the Fresno County Hospital; aged 54; died, March 18, of influenza.

**Menno H. Hostetler,** Wichita, Kan.; Starling-Ohio Medical College, Columbus, 1911; member of the Kansas Medical Society; county health officer; aged 50; died, April 10, in a hotel at Topeka, of angina pectoris.

**John Vincent O'Connor,** St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; aged 64; died, April 5, in St. Joseph's Hospital, of encephalomalacia and arteriosclerosis.

**Omar Joseph Massey,** Wheeling, W. Va.; Ohio State University College of Medicine, Columbus, 1931; intern, Wheeling Hospital; aged 38; died, April 20, of injuries received in an automobile accident.

**Louis J. Wolfort,** St. Louis; Missouri Medical College, St. Louis, 1895; member of the Missouri State Medical Association; aged 59; died, April 18, in the Josephine Hospital, of streptococcus cellulitis.

**John Walter Lambert,** Tangipahoa, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1887; for many years mayor of Tangipahoa; aged 70; died, March 28, of uremia and nephritis.

**Abraham Blumenfeld,** Boston; Tufts College Medical School, Boston, 1929; member of the Massachusetts Medical Society; aged 26; died, January 27, in the Beth Israel Hospital, of renal calculus.

**James Ralph Higgins** ⊕ Gillespie, Ill.; St. Louis University School of Medicine, 1913; served during the World War; aged 45; died, April 18, at the St. Francis Hospital, Litchfield, of heart disease.

**James McIlwain,** Okawville, Ill.; University of the City of New York Medical Department, 1868; member of the Illinois State Medical Society; aged 88; died, April 20, of influenza and arteriosclerosis.

**James W. Beck,** Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1881; formerly coroner of Polk County; aged 74; died, April 24, of coronary thrombosis and arteriosclerosis.

**Edward Ralph Cotham** ⊕ Monticello, Ark.; Jefferson Medical College of Philadelphia, 1903; served during the World War; aged 51; died, April 30, of arteriosclerosis and coronary occlusion.

**Peter Thomas Burns** ⊕ Chicago; Northwestern University Medical School, Chicago, 1891; for many years assistant professor of anatomy at his alma mater; aged 67; died, May 10, of myocarditis.

**William Oscar Spencer,** Multnomah, Ore.; Cooper Medical College, San Francisco, 1897; member of the Oregon State Medical Society; aged 65; died, February 25, of progressive muscular atrophy.

**Herbert Lee McKown,** Tunkhannock, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1894; member of the Medical Society of the State of Pennsylvania; aged 61; died, February 4.

**Albert H. Hattan,** Peru, Ill.; American Medical College, St. Louis, 1877; Chicago Homeopathic Medical College, 1893; aged 74; died, April 26, in Cadiz, Ohio, of heart disease and arteriosclerosis.

**Albert Leonard Miller** ⊕ Marysville, Calif.; Rush Medical College, Chicago, 1896; aged 60; on the staff of the Rideout Memorial Hospital, where he died, March 22, of coronary thrombosis.

**William J. J. Paris,** Rosiclare, Ill.; University of Tennessee Medical Department, Nashville, 1882; member of the Illinois State Medical Society; aged 78; died, March 21, of pneumonia.

**Allen Lowery,** Blackwell, Okla.; University of Louisville (Ky.) School of Medicine, 1891; aged 71; died, April 24, of cerebral hemorrhage, following an operation for intestinal obstruction.

**Clarence Eugene Applegate,** Long Beach, Calif.; Rush Medical College, Chicago, 1927; aged 33; died in April at a local hospital of a skull fracture received in an automobile accident.

**John McK. Wyatt,** Madison, Wis.; University of Nashville (Tenn.) Medical Department, 1878; aged 83; died, April 11, in the Madison General Hospital, of bronchopneumonia.

**James McPherson Templeton** ⊕ Cary, N. C.; Baltimore Medical College, 1882; served during the World War; aged 76; died, May 1, in a hospital at Raleigh, of heart disease.

## AN APHRODISIAC FRAUD

### Robert L. Teycer Mail-Order Fake Debarred from the Mails

On April 2, 1932, the Postmaster General, acting on the recommendation of Judge Horace J. Donnelly, Solicitor for the Post Office Department, issued a fraud order against Dr. Teycer, Dr. B. L. Teycer, Progressive Chemical Association, Teycer Mail Order Company, all of Chicago, and their officers and agents as such. Judge Donnelly in his memorandum to the Postmaster General reported, in effect, that the facts were as follows:

Robert L. Teycer, who is not a physician, had advertised in the matrimonial magazine, *King Cupid*, as follows:

> EXTRA DOUBLE STRENGTH VIGORENE
>
> Amazing Vim, Vigor, Staying power, Endurance. Master Medicine. Stimulates spinal genital center, recharges system at same time. No disappointments. $1.50. 2 boxes $2.50. Dr. Teycer, Box 1275KC. Chicago. Circular free

Those that answered the advertisement received circular matter from Teycer, in which it was stated that "after years of research work, chemical and physical tests, Dr. B. L. Teycer, Ph.C., one of the world's greatest chemists, has discovered one of the main causes of lost nature, lost manhood, poor endurance and staying power, and low sexual power." There was much more of the same sort. The alleged aphrodisiac which Robert L. Teycer sold had, according to the federal report, the following formula:

| | |
|---|---|
| Reduced Iron | ½ grain (or ¼ grain) |
| Quinine Sulphate | ¼ grain |
| Pulv. Capsicum | 1/20 grain |
| Strychnine Sulphate | 1/30 grain |
| Arsenic Trioxide | 1/60 grain |
| Formin | 1 grain |
| Buchu | 1 grain |
| Zinc Phosphide | 1/10 grain |
| Aloin | ¼ grain |
| Ergotin (Bonjean) | ¼ grain |
| Metagen ABC VITAMINS (Parke, Davis & Co.) | 3 grains |

The government brought out at the hearing that the claims made for Vigorene were false and fraudulent and that the stuff would not restore "lost manhood" to impotent old men, as represented. It was brought out, too, that the preparation did not contain significant quantities of the vitamins A, B or C, while some of the various drugs included in the preparation might easily have a deleterious effect on certain persons by causing or aggravating digestive disorders.

Teycer, according to the report, formerly operated a small drug store in Chicago, which was recently taken over by creditors. Instead of having "spent thousand of dollars making physical and chemical tests," as claimed, it was brought out at the hearing that Teycer simply selected some drugs which he found listed in a manual and incorporated them in the formula. As a result, Judge Donnelly declared that the scheme was one for obtaining money through the mails by means of false and fraudulent pretenses and recommended the issuance of a fraud order.

### "PHYSIOLOGIC DEATH AND ARTIFICIAL RESPIRATION"

*To the Editor:*—The editorial comment on this subject (The Journal, April 23) suggests a question and a note of information:

Is it possible for a patient to be resuscitated (after the heart has definitely stopped) by means of artificial respiration?

In the absence of specific cardiac therapy, such as intracardiac epinephrine, has any evidence ever been adduced to indicate that a heart which has actually stopped will once more take up its physiologic function? Was it not meant, in this reference, when the heart *apparently* ceases to function? I gather that this must be so, because farther along you refer to physiologic death having occurred thirty minutes before the heart stopped beating.

The point I wish to make is that in so-called physiologic death we may consider that the heart does continue to beat, even though this action is not audible or palpable; and that when the heart does cease to beat, actual death takes place, at once.

So much for the question. The second part of the editorial comment deals with the expert administration of artificial respiration by laymen. It is well known that the technic available to such personnel is altogether limited to the application of the Schäfer prone pressure method with or without the use of an inhalator, making available oxygen and carbon dioxide by inhalation. The editorial comment continues to elaborate on the efficiency of this technic, failing, first of all, to designate the degree of asphyxia in which such methods may prove useful, these cases being practically limited to the semiconscious, partially asphyxiated patient. No mention whatever is made of the rational and accepted methods whereby the physician may complement and in many cases entirely supplant the efforts of such lay personnel. I refer directly to technic which I have repeatedly described and which is gaining in popularity, as it becomes known and available to the physician. This consists of exposure of the airway by a pocket flashlight laryngoscope, removal of foreign matter, such as blood, vomitus and sea water, from the oropharyngotracheobronchial airway, and the introduction of oxygen and carbon dioxide directly into the trachea, under direct vision and under a measured pressure. This technic is the only possible method of resuscitating the asphyxiated, relaxed, apneic patient whose circulation has failed or is no longer perceptible. It is the only technic by which immediate oxygenation, central carbon dioxide stimulation, and stimulation by the Herring-Breuer reflex may be accomplished.

The condition of the patient to be treated presents a field which is so free from resistance through the absence of muscle tone and reflexes that the necessary instrumentation is entirely nontraumatic. I believe, therefore, that emphasis should be placed on the duties incumbent on the physician in the treatment of those dying from asphyxia, instead of turning over this vital field of medicine to the care of any lay group that may be sufficiently interested to deal with it.

P. J. Flagg, M.D., New York.

## *Queries and Minor Notes*

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### OBESITY OF GLANDULAR ORIGIN

*To the Editor.*—I have under my care a woman, aged 22, suffering from amenorrhea. She appeared normal in every way, puberty occurring at 14, until she was about 16 years of age, when she began to develop rapidly, was 5 feet 10 inches (178 cm.) tall and weighed 200 pounds (90 Kg.). In the past two years she has not gained in height but weighs 260 pounds (118 Kg.). Her menses were normal until one year ago, when the amount gradually became less but the periods regular. Six months ago there was no flow, and menstruation has occurred only once since, and then it was scanty. She has a ravenous appetite and a craving for food. An adenoma of the thyroid developed following the taking of "Marmola" tablets two years ago. I have had her on mixed gland treatment now for two and one-half months without results. Please suggest treatment. Please omit name.

M.D., Canada.

Answer.—The amenorrhea and obesity in this case are undoubtedly due to a disturbance in one or more glands of internal secretion. The gland most likely responsible here is the pituitary and the patient has the condition known as the adipogenital dystrophy of Fröhlich. This disease is due to hypopituitarism, and the chief clinical signs are adiposity and hypoplasia of the genitalia. The latter is the cause of the amenorrhea characteristic of these cases. It was formerly held by some authorities that obesity produced amenorrhea, whereas others maintained that the reverse was true. It is now known that both the obesity and the amenorrhea are due to diminished function of the hypophyseal gland. This has been proved experimentally in animals by partial removal of the hypophysis.

Not infrequently the thyroid gland is responsible for amenorrhea, and this may occur either with hyperthyroidism or with hypothyroidism. On the other hand, in both of these abnormal conditions the menstrual flow may be normal in amount or even increased. Generally speaking, amenorrhea is more frequently associated with hyperthyroidism than with hypothyroidism.

The patient should have a complete physical examination, including at least one basal metabolism test. Because of the adenoma of the thyroid which developed after the taking of thyroid extract (each Marmola tablet contains one-half grain of thyroid), great caution should be used in the administration of more thyroid, Compound Solution of Iodine U. S. P. (Lugol's solution) or other specific thyroid therapy. Because of the most likely hypofunction of the pituitary gland, large doses of extract of the anterior lobe of the pituitary may be tried hypodermically. N. N. R., 1931, page 309, states that oral administration has not been found of value.

## ACQUIRED PROGRESSIVE KINKING OF THE HAIR

*To the Editor:*—A robust unmarried man, aged 34, until ten years ago had a fine, thick head of brown hair. He had severe dandruff, however, and it formed in plaques, probably psoriasis, so that on one occasion while combing he tore off a plaque with the result that he drew blood. A scab formed, this in turn was torn off, and the process was repeated until a patch as big as a 25 cent piece became denuded of hair. He consulted advice with the result that the abrasion healed and the bald area, which was smooth and depressed, shortly grew new hair, which was coarse, black and brittle. He now has at the site of this sore a bump in his scalp over which the scalp is freely movable. The process nevertheless has extended to the entire scalp, so that the hair is black and stiff and wirelike, especially in the parietal areas. The individual hair is no longer a cylinder but is flattened in one diameter and is somewhat like a blade of grass. The hair is kinky, although there are no nodules, as in monilethrix or trichorrhexis nodosa. The hair appears as though it came through its follicle in a special tortuous manner. The hair pulls out easily and painlessly, and the erupted end instead of having the usual normal small round firm whitish nodule has a black glistening sticky soft bead, which can be readily detached from the shaft. At present the scalp is extremely clean and there is no seborrhea or scaly dermatitis. However, many strands of hair are showing fine tapering of their extremities so that I fear alopecia may ensue, as it undoubtedly will unless the process may be recognized and treated. There is no grayness of the hair. The rest of the body hair is normal. The bump on the head is apparently deep to the scalp and beneath the fronto-occipital fascia. Kindly omit name.

M.D., Michigan.

Answer.—This case seems to belong to a group recently described for the first time by Wise and Sulzberger as acquired progressive kinking of the scalp hair" (*Arch. Dermat. & Syph.* **25:**99 [Jan.] 1932). The patches of dermatitis and consequent abrasions may have been part of the disease, though the authors mentioned had no such history in their cases, or they may have been coincident. The extent of the involvement of the scalp is greater than in their cases, and there are no nodes on the hair shaft. The soft sticky root ends are also different than they found. There was no lasting alopecia in their cases. They consider the condition a form of late developing nevus. Naturally they thought of no treatment. A description of this unusual case may be sent to Dr. Fred Wise, 200 West Fifty-Ninth Street, New York. If the patient insists on treatment, the ordinary stimulating measures will surely do him no harm and may be beneficial. Massage, vigorous brushing and an ointment of 3 per cent salicylic acid and 5 per cent sulphur in ointment of rose water may be used.

## HAY FEVER IN CENTRAL ILLINOIS

*To the Editor:*—A woman, aged 44, has had a valvular heart lesion, since the age of 5, which has always compensated but has restricted physical exertion all her life. Her general health has always been excellent except for an intense hay fever reaction each year. She has always lived in central Illinois. She is 15 pounds (6.8 Kg.) overweight. All food protein skin tests are negative and so also are the miscellaneous protein tests, such as cat hair, chicken feathers and cattle dander. The ragweed pollens rubbed into a skin abrasion cause a tremendous wheal, an unusually severe reaction most marked with false ragweed but unusually large also to the western and common variety. The following reactions were barely positive: cocklebur, marsh elder, sage brush, mountain cedar, sweet vernal grass, mugwort and wormwood. The patient has been treated three different seasons with hay fever serum; after each hypodermic injection she reports an intense local reaction involving the arm and from the shoulder to the mid forearm, with a great deal of discomfort. She has received no benefit from her serum treatments; rather an exaggeration of her symptoms has resulted, as the onset was earlier and the duration greater in the years when she had the serum than when she had no treatment. Please omit name. M.D., Illinois.

Answer.—The valvular heart lesion is compensated and can therefore be left out of consideration, except that its presence calls for the best possible treatment in order to avoid the severe hay fever reaction which comes each year and which may strain the heart's action. The query does not state just when the hay fever comes on. In central Illinois there are two main seasons: 1. The grass season, due to June grass, timothy, orchard grass and redtop, and beginning about the middle of May and going through June and July. The patient should be tested for these four and, if positive, and if she has symptoms during this period, she should be given injections of a mixture of these four pollen extracts. 2. The weed season, due to the ragweeds, usually short and giant, beginning about August 10 or 15 and going through September usually to the first frost. Assuming that this patient has symptoms in this period, she should be given injections of a mixture of extracts of the short and giant ragweeds (equal parts).

The patient is evidently one of these extremely sensitive persons who must be started with a dilute solution early, and the dosage must be increased slowly. The treatment might begin with 0.02 cc. of a 1:100,000 dilution of the pollen extract (dilutions can be made with sterile physiologic solution of sodium chloride and will keep fairly well if kept on ice). Then each injection may be increased about 50 per cent; in this way one can work up the dosage through 1:10,000; 1:1,100 and finally to 1:100 dilutions. If there is a general reaction, which occurs not infrequently, epinephrine hydrochloride solution, 1:1,000 (from 0.5 to 1 cc.) should be given and the next dose reduced gradually working up again. The procedure demands painstaking care and patience in these sensitive individuals but almost all of them can be raised to a high amount with probable partial or complete relief. With such a patient, injections should be begun at once and given twice weekly.

## DEXTROSE IN OXALATED BLOOD

*To the Editor:*—Will you please give me actual figures (if such are known) on the rate of disappearance of dextrose (*d*-glucose) from oxalated blood standing at room temperature and/or in the ice box. I know that dextrose must be determined at once, but it happens that the oxalated blood will stand around four or five hours before testing at times. I should like to know the rate of deterioration.

Isaac Apperman, M.D., New York.

Answer.—The rate of disappearance of dextrose (*d*-glucose) from blood in vitro varies considerably with the source of the blood, and it may also vary greatly in different samples taken from the same source at different times. The sugar that disappears may in part give rise to lactic acid, another portion may be completely oxidized, while some is probably accounted for by bacterial decomposition.

The rate of disappearance of dextrose does not bear any direct relationship to the level of the blood sugar, so that in general it may be said that blood with a high sugar content loses relatively less dextrose in a given time than blood with a low sugar content. Glycolysis occurs most rapidly at its optimum temperature of 37 C. At icebox temperatures the rate of glycolysis is considerably decreased, as are also, of course, the effects of bacterial action. Citrates and oxalates, when used as anticoagulants, retard glycolysis to only a minor extent.

A recent report shows that defibrinated blood taken and kept with aseptic precautions at 37 C. may lose all its sugar content in from four to six hours. Other workers report that oxalated blood, kept at icebox temperatures (from 9 to 11 C.) may lose from 0 to 90 per cent of the initial dextrose content in twenty-four hours. The loss of sugar in four or five hours from oxalated blood, standing at room temperature, may therefore be considerable. The variability of the rate of this phenomenon in different specimens of blood makes it impossible to give a set figure or to supply a standard correction for such loss.

From a practical point of view it is possible to solve these difficulties by the use of fluorides, which have been shown to arrest glycolysis. A mixture of 1 part of potassium oxalate and 2 parts of sodium fluoride, finely ground and well mixed, may be used for this purpose, in place of the usual powdered oxalate. It is necessary, of course, to use proportionately more of this mixture than of the straight oxalate to prevent coagulation in a given amount of blood.

## ANOMALIES OF BONES OF WRIST

*To the Editor:*—In a case of injury to the wrist of a woman, aged 27, roentgenograms were taken of both wrists. About 1 mm. distal to the styloid process of both ulnas there is a well defined shadow as of bone, regular in outline, about half the size of a buckshot. I am at loss to know what these particles might be. They are referred to as fragments of bone by the roentgenologist. They appear to me as sesamoid formations but I am unable to find any reference in Morris's Anatomy to sesamoids in this location. There is no history of injury to the opposite wrist.

Hubert C. Miller, M.D., Racine, Wis.

Answer.—Small bones may appear distal to the end of the styloid process of the ulna, but they are rather rare. Pfitzner described an antibrachial row of carpal bones just distal to the radius and the ulna. Dwight has observed that it may occasionally be seen located beyond the tip of the styloid process. Thilenius reported that this embryonic bony tissue was common in the early embryo and that in the second month it occurred in 65 per cent of specimens. The persistence of this tissue as bone is rarely seen in the adult. It is possible that, in the development, the tip of the styloid may be separated from the main part of the ulna. It is perfectly possible for sesamoids to occur in this region. They may occur in any location on the hand or fingers and may be multiple. A fracture of the tip of the styloid may fail to heal, and in the absence of evidence of injury to the radius it is difficult to differentiate from a congenital anomaly. A fracture, however, usually shows some irregularity on the side nearer to the ulna and is somewhat concave or flattened. A similar flattening of the base of the styloid process from which it was broken is usually present. On examination, a sesamoid or separate anomalous carpal bone, as the triangulare, should be completely surrounded by a smooth capsule or cartilage, while in a nonunited fracture of the styloid a scar with fibrous tissue should be found on microscopic examination. In the presence of this bony fragment on both sides and in the absence of evidence of injury, the presence of a congenital bony anomaly should be accepted.

## PATHOLOGY OF ELECTRICAL SHOCK

*To the Editor:*—A young man came in contact with a live wire carrying 250 volts, direct current. Points of contact were the back of his neck and his feet. He fell clear. Artificial respiration was applied and he regained consciousness. Thirty minutes later he again became unconscious and again responded to artificial respiration. He remained in the hospital five days at rest. He says he had a headache during that time. Eight days later he apparently became confused mentally and was returned to the hospital for a period of five days. During this time his actions were perfectly normal and he was discharged. This accident occurred two months ago. The patient still complains of a severe headache and of tachycardia. Would you be kind enough to furnish me with any information you have on cases of this kind.

George W. Gay, M.D., Ironton, Mo.

Answer.—A path of electrical conduction that includes the head, neck and thorax is far more likely to be disastrous than one extending only from the abdominal region to the feet. The path that extends through the head is in turn of greater significance than that through the neck or thorax. This is recognized in most legal electrical executions, as one electrode is commonly placed on the head. Although neuroses subsequent to electrical shock are prolific and may possibly fully account for the manifestations in the case cited, genuine organic lesions may be produced apart from burns and at times in the absence of local burns. Capillary hemorrhage in the brain or spinal cord may be followed by chronic states in which increased intracranial pressure may play a part. Cellular changes, including edema, may be demonstrated in any portion of the central nervous system.

Electrical paths embracing the neck may lead to damage to the vagus nerves, which in the present case may account for the persistent tachycardia. The ventricular fibrillation, long associated with electrical shock, involving the heart, may not spontaneously clear up, and extensive permanent or prolonged harm may be produced. Cases similar to the one described are well known and might be cited, but information is likely to be found in experimental studies such as the following:

Factors in the Production of Nervous Lesions Following Electric Shock, *J. Indust. Hyg.*, March, 1932, p. 87.

Experimental Electric Shock, *J. Indust. Hyg.*, April, 1927, p. 140.

Histopathology of Different Types of Electric Shock on Mammalian Brains, *J. Indust. Hyg.*, November, 1930, p. 324.

## SATIN WOOD DERMATITIS

*To the Editor:*—Can you give me any information as to symptoms and treatment of dermatitis due to contact or handling of satin wood, which is used as trimming in the manufacture of furniture?

J. E. Bolender, M.D., Grand Rapids, Mich.

Answer.—Satinwood is one of the most irritating of woods, and dermatitis from it is common among woodworkers. This is a form of simple dermatitis, dermatitis venenata, occurring as a macular, maculopapular, papular or vesicular eruption in groups, the general lesions close together or fused, the peripheral lesions farther and farther apart as they are farther from the center, wherefore the patch is ill defined. Exposed parts are first involved, but the eruption may spread to other parts or become even general. It itches intensely in the acute stage. If it is vesicular, cool wet dressings of 6 per cent solution of aluminum acetate in distilled water should be used, or saturated solution of boric acid, changed as often as they become warm, not thickly applied or closely covered for fear of preventing radiation of heat. This treatment may be alternated with calamine lotion, pulverized calamine and zinc oxide, 8 Gm. of each, in solution of calcium hydroxide, 120 cc. For the macular or papular eruptions, and for the moist ones after they have been dried by the lotion treatment, plain zinc paste, zinc oxide and starch, 25 per cent of each, in petrolatum or ointment of rose water to 100 per cent. This should be applied thinly several times a day and removed, when necessary, with oil or ointment of rose water. Internally, injections of the patient's own blood may hasten recovery, or intravenous or intramuscular injections of calcium gluconate or calcium lactate by mouth, 4 Gm., dissolved in hot water after each meal. After the attack has subsided the patient must obtain work where no satinwood is used, or an attempt may be made to desensitize; but this is difficult.

## *ETHER AS ANESTHETIC FOR TONSILLECTOMY*

*To the Editor:*—Please advise me concerning these points about the after-effects of ether as an anesthetic given by the drop method: Could pains in the chest of a girl, aged 18 years, have any connection with the fact that she took ether three weeks previously, during a tonsil operation? She had no trouble after the operation until the onset of the pain and nothing could be made out on physical examination of the chest to account for the pain. Could the fact that a boy, aged 6 years, who took ether for a tonsillectomy, account for his getting dizzy and having violent headaches every time he remains in sunshine for any length of time, or if he gets hot in a warm room? I had nothing to do with giving the ether or with either tonsillectomy. It is my contention that ether quickly leaves the body and, barring ether pneumonia and rapid bronchial irritation, does not cause trouble to the taker. Please omit name.

M.D., Texas.

Answer.—The local action of a concentrated ether vapor occasionally causes a lung complication; such complications, however, occur within the first day or two after the anesthesia. Occasionally lung abscess develops after tonsillectomies and is due to the inhalation of solid food vomited during the operation or, more frequently, to infected material from the tonsils or to tonsillar tissue having been aspirated and lodged in the lung. The latter condition would be late in developing and during the early stages may be difficult to diagnose. A roentgenogram is usually of considerable value in clearing up the situation.

As ether is soon eliminated from the body, it is improbable that there is any connection between it and the boy's headache. Doubtless the pain is a coincidence and not the result of the ether anesthesia.

## SYPHILIS IN PREGNANCY

*To the Editor:*—A woman, two and one-half months pregnant, has a chancre on the left labium minus and an inguinal adenitis on the corresponding side. The Kahn test of the blood is three plus positive. The chancre is of three weeks' duration, according to the history. I should like your opinion as to the probability of a nonsyphilitic child at term if treatment is carried out energetically during pregnancy. Also advise as to how close to term the treatment should be carried and how soon after delivery it could be resumed if delivery is not complicated. If, for any reason, the patient could not or would not continue treatment, is termination of the pregnancy justified? She has been deserted by her husband and is of limited means and must be self supporting. Please omit name.

M.D., Oklahoma.

Answer.—If energetic antisyphilitic treatment is given throughout the entire pregnancy, the outlook for a healthy baby is good. The treatment should be carried out continuously right up to the time of delivery and then begun again about two weeks after labor, unless there is some contraindication, such as puerperal fever. The baby should be carefully examined for evidences of syphilis. This means not only a thorough physical examination but also roentgenograms of the large bones. Wassermann and Kahn tests should be made on the child's blood at frequent intervals.

Syphilis is not an indication for the interruption of pregnancy even if the patient refuses treatment and even if there are social reasons why it is better for the patient not to be burdened with a child. In every large city there are a number of dispensaries or clinics where antisyphilitic therapy is given at low rates or free of charge. Furthermore, in the presence of active syphilis there is great danger of infection if the uterus is tampered with to produce an abortion.

## INFLAMMATION OF PENIS

*To the Editor:*—I have a patient, aged 50, who is suffering (and suffering is right) from a chronic inflammation of the erectile tissue of the penis. The Wassermann reaction is negative. Right back of the head, the penis is circled with a band of hard fibrous tissue. Erection is complete up to this band but beyond it the penis remains soft and flabby. Will you kindly advise as to treatment and prognosis? Kindly omit name.

M.D., Montana.

Answer.—The symptoms described fit the picture of induratio penis plastica. The condition, which affects individuals between the ages of 45 and 60, is inflammatory in nature and involves the corpora cavernosa only. It is characterized pathologically by the presence of single or multiple fibrous plaques which begin at one point along the shaft and form circumscribed masses with sharply defined margins. The entire penis may be involved. The induration never becomes malignant nor does it ulcerate. The prognosis, in view of the pathology, is poor. Treatment is of little, if any, avail. The condition is not amenable to drugs. Direct treatment with diathermy, x-rays or radium offers questionable results. Extirpation may have to be resorted to.

### RECTAL ETHER AND LUNG IRRITATION

*To the Editor:*—Will you kindly give me your opinion as to whether or not rectal ether anesthesia (Gwathmey method) is contraindicated in infections of the respiratory tract because of the danger of ether pneumonia during the period of elimination of the ether from the body through the respiratory system, and if this danger really exists.

C. B. Caldwell, M.D., San Francisco.

Answer.—Experimental proof and observation of large numbers of patients who have respiratory trouble following ether anesthesia brings out one fact more prominently than any other, and that is the danger of administrating concentrated ether vapor. Offergeld (*Arch. f. klin. Chir.* **47**:175, 1898) found that closed methods of administration with high ether concentrations were followed by desquamation of bronchial epithelium, patches of lung consolidation and hemorrhage into the alveoli. The only complication following open administration with weak vapors was slight destruction of the epithelium, which became regenerated within a few days. Such observations indicate quite clearly that when ether affects the lungs it does so by its direct local action during its administration.

While it is true that ether is eliminated principally by the lungs, regardless of the method of its administration, there is doubt whether it is sufficiently concentrated in rectal anesthesia to affect the lungs.

### ALCOHOL AND STRYCHNINE

*To the Editor:*—In case a man had been drinking alcohol and had been drinking previous to taking poison and then was to take a dose of strychnine dissolved in alcohol, might the effect of his drinking alcohol act on him so that he would not present the typical symptoms of strychnine poisoning, and might the fact of his drinking alcohol act as an antidote so that it might not kill him as quickly as it would otherwise? I have been unable to find any material on this question. Kindly omit name.

M.D., Iowa.

Answer.—A sufficient dose of alcohol in the system would no doubt profoundly influence the clinical picture of strychnine poisoning. Indeed, if the individual should be in that stage of alcohol narcosis in which the spinal reflexes are paralyzed, the strychnine convulsions even might be lacking. In this manner, alcohol might act as an antagonist to strychnine.

### IMMUNIZATION AGAINST SCARLET FEVER

*To the Editor:*—What is the value of active immunization against scarlet fever? The prophylactic treatment with serum in scarlet fever? The treatment of scarlet fever by specific antitoxins and serums?

Oscar E. Fox, M.D., Reading, Pa.

Answer.—Active immunization against scarlet fever properly carried out to the point of negative skin test protects against the disease. Prophylactic treatment with scarlet fever antitoxin affords only temporary protection. It should be followed by active immunization with the toxin. Scarlet fever antitoxin is a valuable remedy. Administered early in the disease, it gives striking results in reducing the incidence and severity of complications, in addition to relieving the toxemia.

### PHLYCTENULAR CONJUNCTIVITIS

*To the Editor:*—Kindly give me the latest treatment for phlyctenular conjunctivitis.

William F. Tyler, M.D., Beaumont, Texas.

Answer.—1. Local: Silver nitrate, 1 per cent, instilled once daily or every other day, until the secretion is stopped. A mild cleansing wash, such as 1 : 5,000 mercuric oxycyanide or 1 : 2,500 metaphen, to be used in an eye cup two or three times daily. Yellow mercuric oxide ointment instilled at bedtime.

2. General: Free catharsis. Treatment and eradication of nasal or tonsillar disorders. Such general hygienic measures as are necessary to bring the general physical condition to normal.

### ARTHRITIS AND POLYCYSTIC KIDNEY

*To the Editor:*—I have just completed a case of severe arthritis deformans in a man, aged 68. The condition began about twelve years ago. He had always been a healthy vigorous man before. At the postmortem, both kidneys and the liver were polycystic. In your opinion is there any relation between the postmortem observations and the arthritis?

Merrill S. Davis, M.D., Marion, Ind.

Answer.—So far as known at the present time there is no reason to believe that there was any relation between the arthritis and the polycystic condition of the kidneys and liver.

Georgia: Atlanta, June 15-16. Joint Sec., Mr. R. C. Coleman, 111 State Capitol Bldg., Atlanta.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48, Young Bldg., Honolulu.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Indiana: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

Iowa: Iowa City, June 7-9. Dir., Mr. H. W. Grefe, Capitol Building, Des Moines.

Kansas: Kansas City, June 21-22. Sec., Dr. C. H. Ewing, Larned.

Kentucky: Louisville, June 8-10. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.

Louisiana: New Orleans, June 9-11. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Maryland: *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore. *Regular.* Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

Massachusetts: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

Michigan: Ann Arbor and Detroit, June 7-9. Sec., Dr. Nelson McLaughlin, 1010 Maccabee Bldg., Detroit.

Minnesota: *Basic Science.* Minneapolis, June 7-8. Sec., Dr. J. Charmley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Regular.* Minneapolis, June 21-23. Sec., Dr. E. J. Engberg, 524 Lowry Medical Arts Bldg., St. Paul.

Missouri: St. Louis, June 14-16. Sec., Dr. James Stewart, Capitol Bldg., Jefferson City.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

Nebraska: *Regular.* Omaha, June 9-11. Dir., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315, State Education Bldg., Albany.

North Carolina: Raleigh, June 20. Sec., Dr. John W. MacConnell, Davidson.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, June 7-10. Sec., Dr. H. M. Platter, 85 E. Gay St., Columbus.

Oklahoma: Oklahoma City, June 8-10. Sec., Dr. J. M. Byrum, Shawnee.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg.; Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Texas: Marlin, June 21-23. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Vermont: Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 15-18. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

West Virginia: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

Wyoming: Cheyenne, June 6. Sec., Dr. W. H. Hassed, Capitol Bldg., Cheyenne.

differentiate from a congenital anomaly. A fracture, however, usually shows some irregularity on the side nearer to the ulna and is somewhat concave or flattened. A similar flattening of the base of the styloid process from which it was broken is usually present. On examination, a sesamoid or separate anomalous carpal bone, as the triangulare, should be completely surrounded by a smooth capsule or cartilage, while in a nonunited fracture of the styloid a scar with fibrous tissue should be found on microscopic examination. In the presence of this bony fragment on both sides and in the absence of evidence of injury, the presence of a congenital bony anomaly should be accepted.

### PATHOLOGY OF ELECTRICAL SHOCK

*To the Editor:*—A young man came in contact with a live wire carrying 250 volts, direct current. Points of contact were the back of his neck and his feet. He fell clear. Artificial respiration was applied and he regained consciousness. Thirty minutes later he again became unconscious and again responded to artificial respiration He remained in the hospital five days at rest. He says he had a headache during that time. Eight days later he apparently became confused mentally and was returned to the hospital for a period of five days. During this time his actions were perfectly normal and he was discharged. This accident occurred two months ago. The patient still complains of a severe headache and of tachycardia. Would you be kind enough to furnish me with any information you have on cases of this kind.

George W. Gay, M.D., Ironton, Mo.

Answer.—A path of electrical conduction that includes the head, neck and thorax is far more likely to be disastrous than one extending only from the abdominal region to the feet. The path that extends through the head is in turn of greater significance than that through the neck or thorax. This is recognized in most legal electrical executions, as one electrode is commonly placed on the head. Although neuroses subsequent to electrical shock are prolific and may possibly fully account for the manifestations in the case cited, genuine organic lesions may be produced apart from burns and at times in the absence of local burns. Capillary hemorrhage in the brain or spinal cord may be followed by chronic states in which increased intracranial pressure may play a part. Cellular changes, including edema, may be demonstrated in any portion of the central nervous system.

Electrical paths embracing the neck may lead to damage to the vagus nerves, which in the present case may account for the persistent tachycardia. The ventricular fibrillation, long associated with electrical shock, involving the heart, may not spontaneously clear up, and extensive permanent or prolonged harm may be produced. Cases similar to the one described are well known and might be cited, but information is likely to be found in experimental studies such as the following:

Factors in the Production of Nervous Lesions Following Electric Shock, *J. Indust. Hyg.*, March, 1932, p. 87.
Experimental Electric Shock, *J. Indust. Hyg.*, April, 1927, p. 140.
Histopathology of Different Types of Electric Shock on Mammalian Brains, *J. Indust. Hyg.*, November, 1930, p. 324.

### SATIN WOOD DERMATITIS

*To the Editor:*—Can you give me any information as to symptoms and treatment of dermatitis due to contact or handling of satin wood, which is used as trimming in the manufacture of furniture?

J. E. Bolender, M.D., Grand Rapids, Mich.

Answer.—Satinwood is one of the most irritating of woods, and dermatitis from it is common among woodworkers. This is a form of simple dermatitis, dermatitis venenata, occurring as a macular, maculopapular, papular or vesicular eruption in groups, the general lesions close together or fused, the peripheral lesions farther and farther apart as they are farther from the center, wherefore the patch is ill defined. Exposed parts are first involved, but the eruption may spread to other parts or become even general. It itches intensely in the acute stage. If it is vesicular, cool wet dressings of 6 per cent solution of aluminum acetate in distilled water should be used, or saturated solution of boric acid, changed as often as they become warm, not thickly applied or closely covered for fear of preventing radiation of heat. This treatment may be alternated with calamine lotion, pulverized calamine and zinc oxide, 8 Gm. of each, in solution of calcium hydroxide, 120 cc. For the macular or papular eruptions, and for the moist ones after they have been dried by the lotion treatment, plain zinc paste, zinc oxide and starch, 25 per cent of each, in petrolatum or ointment of rose water to 100 per cent. This should be applied thinly several times a day and removed, when necessary, with oil or ointment of rose water. Internally, injections of the patient's own blood may hasten recovery, or intravenous or intramuscular injections of calcium gluconate or calcium lactate by mouth, 4 Gm., dissolved in hot water after each meal. After the attack has subsided the patient must obtain work where no satinwood is used, or an attempt may be made to desensitize; but this is difficult.

### ETHER AS ANESTHETIC FOR TONSILLECTOMY

*To the Editor:*—Please advise me concerning these points about the after-effects of ether as an anesthetic given by the drop method: Could pains in the chest of a girl, aged 18 years, have any connection with the fact that she took ether three weeks previously, during a tonsil operation? She had no trouble after the operation until the onset of the pain and nothing could be made out on physical examination of the chest to account for the pain. Could the fact that a boy, aged 6 years, who took ether for a tonsillectomy, account for his getting dizzy and having violent headaches every time he remains in sunshine for any length of time, or if he gets hot in a warm room? I had nothing to do with giving the ether or with either tonsillectomy. It is my contention that ether quickly leaves the body and, barring ether pneumonia and rapid bronchial irritation, does not cause trouble to the taker. Please omit name.

M.D., Texas.

Answer.—The local action of a concentrated ether vapor occasionally causes a lung complication; such complications, however, occur within the first day or two after the anesthesia. Occasionally lung abscess develops after tonsillectomies and is due to the inhalation of solid food vomited during the operation or, more frequently, to infected material from the tonsils or to tonsillar tissue having been aspirated and lodged in the lung. The latter condition would be late in developing and during the early stages may be difficult to diagnose. A roentgenogram is usually of considerable value in clearing up the situation.

As ether is soon eliminated from the body, it is improbable that there is any connection between it and the boy's headache. Doubtless the pain is a coincidence and not the result of the ether anesthesia.

### SYPHILIS IN PREGNANCY

*To the Editor:*—A woman, two and one-half months pregnant, has a chancre on the left labium minus and an inguinal adenitis on the corresponding side. The Kahn test of the blood is three plus positive. The chancre is of three weeks' duration, according to the history. I should like your opinion as to the probability of a nonsyphilitic child at term if treatment is carried out energetically during pregnancy. Also advise as to how close to term the treatment should be carried and how soon after delivery it could be resumed if delivery is not complicated. If, for any reason, the patient could not or would not continue treatment, is termination of the pregnancy justified? She has been deserted by her husband and is of limited means and must be self supporting. Please omit name.

M.D., Oklahoma.

Answer.—If energetic antisyphilitic treatment is given throughout the entire pregnancy, the outlook for a healthy baby is good. The treatment should be carried out continuously right up to the time of delivery and then begun again about two weeks after labor, unless there is some contraindication, such as puerperal fever. The baby should be carefully examined for evidences of syphilis. This means not only a thorough physical examination but also roentgenograms of the large bones. Wassermann and Kahn tests should be made on the child's blood at frequent intervals.

Syphilis is not an indication for the interruption of pregnancy even if the patient refuses treatment and even if there are social reasons why it is better for the patient not to be burdened with a child. In every large city there are a number of dispensaries or clinics where antisyphilitic therapy is given at low rates or free of charge. Furthermore, in the presence of active syphilis there is great danger of infection if the uterus is tampered with to produce an abortion.

### INFLAMMATION OF PENIS

*To the Editor:*—I have a patient, aged 50, who is suffering (and suffering is right) from a chronic inflammation of the erectile tissue of the penis. The Wassermann reaction is negative. Right back of the head, the penis is circled with a band of hard fibrous tissue. Erection is complete up to this band but beyond it the penis remains soft and flabby. Will you kindly advise as to treatment and prognosis? Kindly omit name.

M.D., Montana.

Answer.—The symptoms described fit the picture of induratio penis plastica. The condition, which affects individuals between the ages of 45 and 60, is inflammatory in nature and involves the corpora cavernosa only. It is characterized pathologically by the presence of single or multiple fibrous plaques which begin at one point along the shaft and form circumscribed masses with sharply defined margins. The entire penis may be involved. The induration never becomes malignant nor does it ulcerate. The prognosis, in view of the pathology, is poor. Treatment is of little, if any, avail. The condition is not amenable to drugs. Direct treatment with diathermy, x-rays or radium offers questionable results. Extirpation may have to be resorted to.

### RECTAL ETHER AND LUNG IRRITATION

*To the Editor:*—Will you kindly give me your opinion as to whether or not rectal ether anesthesia (Gwathmey method) is contraindicated in infections of the respiratory tract because of the danger of ether pneumonia during the period of elimination of the ether from the body through the respiratory system, and if this danger really exists.

C. B. Caldwell, M.D., San Francisco.

Answer.—Experimental proof and observation of large numbers of patients who have respiratory trouble following ether anesthesia brings out one fact more prominently than any other, and that is the danger of administrating concentrated ether vapor. Offergeld (*Arch. f. klin. Chir.* **47**:175, 1898) found that closed methods of administration with high ether concentrations were followed by desquamation of bronchial epithelium, patches of lung consolidation and hemorrhage into the alveoli. The only complication following open administration with weak vapors was slight destruction of the epithelium, which became regenerated within a few days. Such observations indicate quite clearly that when ether affects the lungs it does so by its direct local action during its administration.

While it is true that ether is eliminated principally by the lungs, regardless of the method of its administration, there is doubt whether it is sufficiently concentrated in rectal anesthesia to affect the lungs.

### ALCOHOL AND STRYCHNINE

*To the Editor:*—In case a man had been drinking alcohol and had been drinking previous to taking poison and then was to take a dose of strychnine dissolved in alcohol, might the effect of his drinking alcohol act on him so that he would not present the typical symptoms of strychnine poisoning, and might the fact of his drinking alcohol act as an antidote so that it might not kill him as quickly as it would otherwise? I have been unable to find any material on this question. Kindly omit name.

M.D., Iowa.

Answer.—A sufficient dose of alcohol in the system would no doubt profoundly influence the clinical picture of strychnine poisoning. Indeed, if the individual should be in that stage of alcohol narcosis in which the spinal reflexes are paralyzed, the strychnine convulsions even might be lacking. In this manner, alcohol might act as an antagonist to strychnine.

### IMMUNIZATION AGAINST SCARLET FEVER

*To the Editor:*—What is the value of active immunization against scarlet fever? The prophylactic treatment with serum in scarlet fever? The treatment of scarlet fever by specific antitoxins and serums?

Oscar E. Fox, M.D., Reading, Pa.

Answer.—Active immunization against scarlet fever properly carried out to the point of negative skin test protects against the disease. Prophylactic treatment with scarlet fever antitoxin affords only temporary protection. It should be followed by active immunization with the toxin. Scarlet fever antitoxin is a valuable remedy. Administered early in the disease, it gives striking results in reducing the incidence and severity of complications, in addition to relieving the toxemia.

### PHLYCTENULAR CONJUNCTIVITIS

*To the Editor:*—Kindly give me the latest treatment for phlyctenular conjunctivitis.

William F. Tyler, M.D., Beaumont, Texas.

Answer.—1. Local: Silver nitrate, 1 per cent, instilled once daily or every other day, until the secretion is stopped. A mild cleansing wash, such as 1:5,000 mercuric oxycyanide or 1:2,500 metaphen, to be used in an eye cup two or three times daily. Yellow mercuric oxide ointment instilled at bedtime.

2. General: Free catharsis. Treatment and eradication of nasal or tonsillar disorders. Such general hygienic measures as are necessary to bring the general physical condition to normal.

### ARTHRITIS AND POLYCYSTIC KIDNEY

*To the Editor:*—I have just completed a case of severe arthritis deformans in a man, aged 68. The condition began about twelve years ago. He had always been a healthy vigorous man before. At the postmortem, both kidneys and the liver were polycystic. In your opinion is there any relation between the postmortem observations and the arthritis?

Merrill S. Davis, M.D., Marion, Ind.

Answer.—So far as known at the present time there is no reason to believe that there was any relation between the arthritis and the polycystic condition of the kidneys and liver.

# Council on Medical Education and Hospitals

## COMING EXAMINATIONS

Alabama: Montgomery, July 11. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

Arizona: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave., Phoenix.

California: *Reciprocity.* Los Angeles and San Francisco, June 15. *Regular.* San Francisco, July 11-14. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Basic Science.* New Haven, June 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Regular.* Hartford, July 12-13. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic.* New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

Delaware: Wilmington, June 14-16. Sec., Dr. Harold L. Springer, 1013 Washington St., Wilmington.

District of Columbia: *Basic Science.* Washington, June 29-30. *Regular.* Washington, July 11-12. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Florida: Tampa, June 13-14. Sec., Dr. W. M. Rowlett, 812 Citizens Bank Bldg., Tampa.

Georgia: Atlanta, June 15-16. Joint Sec., Mr. R. C. Coleman, 111 State Capitol Bldg., Atlanta.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48, Young Bldg., Honolulu.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Indiana: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

Iowa: Iowa City, June 7-9. Dir., Mr. H. W. Grefe, Capitol Building, Des Moines.

Kansas: Kansas City, June 21-22. Sec., Dr. C. H. Ewing, Larned.

Kentucky: Louisville, June 8-10. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.

Louisiana: New Orleans, June 9-11. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Maryland: *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore. *Regular.* Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

Massachusetts: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

Michigan: Ann Arbor and Detroit, June 7-9. Sec., Dr. Nelson McLaughlin, 1010 Maccabee Bldg., Detroit.

Minnesota: *Basic Science.* Minneapolis, June 7-8. Sec., Dr. J. Charmley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Regular.* Minneapolis, June 21-23. Sec., Dr. E. J. Engberg, 524 Lowry Medical Arts Bldg., St. Paul.

Missouri: St. Louis, June 14-16. Sec., Dr. James Stewart, Capitol Bldg., Jefferson City.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

Nebraska: *Regular.* Omaha, June 9-11. Dir., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315, State Education Bldg., Albany.

North Carolina: Raleigh, June 20. Sec., Dr. John W. MacConnell, Davidson.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, June 7-10. Sec., Dr. H. M. Platter, 85 E. Gay St., Columbus.

Oklahoma: Oklahoma City, June 8-10. Sec., Dr. J. M. Byrum, Shawnee.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Texas: Marlin, June 21-23. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Vermont: Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 15-18. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

West Virginia: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

Wyoming: Cheyenne, June 6. Sec., Dr. W. H. Hassed, Capitol Bldg., Cheyenne.

## Minnesota January Report

Dr. E. J. Engberg, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, Jan. 19-21, 1932. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Forty-three candidates were examined, all of whom passed. Four physicians were licensed by reciprocity with other states and 1 physician was licensed by endorsement. The following colleges were represented:

| PASSED<br>College | Year Grad. | Per Cent |
|---|---|---|
| College of Medical Evangelists | (1931) | 89.6, 90 |
| Stanford University School of Medicine | (1930) | 91.3 |
| University of Colorado School of Medicine | (1929) | 88.2 |
| University of Georgia Medical Department | (1930) | 94.2 |
| Loyola University School of Medicine | (1931) | 90.2 |
| Rush Medical College | (1931) | 93.2, 95 |

## Pennsylvania January Report

Mr. Charles D. Koch, secretary, Pennsylvania State Board of Medical Education and Licensure of the Department of Public Instruction, reports the oral and written examination held at Philadelphia and Pittsburgh, Jan. 5-9, 1932. Thirty-eight candidates were examined, 37 of whom passed and one failed. Six physicians were licensed by reciprocity with other states and three physicians were licensed by endorsement from Jan. 5 to 28, 1932. The following colleges were represented:

| PASSED<br>College | Year Grad. | Number Passed |
|---|---|---|
| University of Colorado School of Medicine | (1929) | 1 |
| Georgetown University School of Medicine | (1930) | 1 |
| Rush Medical College | (1931, 2) | 2 |
| University of Kansas School of Medicine | (1927) | 1 |
| University of Louisville School of Medicine | (1930) | 1 |
| University of Maryland School of Medicine and College of Physicians and Surgeons | (1916) | 1 |
| University of Minnesota Medical School | (1931) | 1 |
| St. Louis University School of Medicine | (1929) | 1 |
| Columbia University Medical Department | (1892) | 1 |
| Hahnemann Medical College and Hospital of Philadelphia | (1928), (1930, 2) | 3 |

## SCHOOLS OFFERING SUMMER COURSES IN 1932

### Prepared by the Council on Medical Education and Hospitals

#### ARKANSAS

University of Arkansas School of Medicine, 300 West Markham Street, Little Rock.—On May 30 the following courses will be offered to undergraduates: physiologic chemistry, histology, embryology and pathology. Courses in gross anatomy and neuro-anatomy will be offered on July 5. Address Frank Vinsonhaler, M.D., dean.

#### CALIFORNIA

Stanford University School of Medicine, 2398 Sacramento Street, San Francisco.—No routine teaching of undergraduate work, but offers special opportunities for study and research to both graduates and medical students in the clinics, wards and laboratories. Work also offered to graduates and undergraduates as "special workers" in the various departments includes pharmacology, pathology, general medicine, diabetes, chest diseases, pediatrics, neuropsychiatry, skin and syphilis, metabolism laboratory, radiology, physical therapy technic, general surgery, fracture clinic, orthopedic surgery, genito-urinary surgery, ophthalmology, otolaryngology, surgical pathology, surgical anatomy, obstetrics and gynecology, and female urology. Minimum attendance is four weeks. Make application to William Ophuls, M.D., dean.

University of California Medical School, Parnassus and Third avenues, San Francisco.—Courses for graduates in medicine will be given from June 6 to June 18. The morning and all-day courses consist of general medicine, general surgery, otorhinolaryngology, genito-urinary diseases, ophthalmology, general pathology, and general clinical pediatrics. The afternoon courses consist of circulatory diseases, diseases of the blood forming organs, diseases of the endocrine glands including diabetes, diseases of the gastro-intestinal tract, special laboratory diagnosis, and operative technic. Ear, nose, and throat surgery will be offered in the evening course. In addition to the regular courses there will be round table discussions, lectures and clinicopathological conferences open to the medical public without charge. Address Langley Porter, M.D., dean.

#### COLORADO

University of Colorado School of Medicine, 4200 East Ninth Avenue, Denver.—Term extends from June 20 to August 26, offering the following courses to graduates and undergraduates in medicine: anatomy, bacteriology, biochemistry, clinical pathology, pathology, physiology and pharmacology. Address Maurice H. Rees, M.D., dean.

#### CONNECTICUT

New Haven School of Physical Therapy, 303 Whitney Avenue, New Haven.—A course for graduates in medicine will be offered on June 6 and August 8. Address Harry Eaton Stewart, M.D., director.

#### DISTRICT OF COLUMBIA

Howard University School of Medicine, Fifth and W streets, N.W., Washington.—During the coming summer, practical work in obstetrics and a limited number of clinical clerkships in medicine and surgery will be offered to undergraduate students. Address Numa P. G. Adams, M D., dean.

#### ILLINOIS

Rush Medical College, University of Chicago, 1758 West Harrison Street, Chicago.—The courses in the third and fourth years of the medical schools are continued at Rush Medical College during the summer quarter in the departments of pathology, medicine, pediatrics, surgery, obstetrics and gynecology, laryngology and otology, ophthalmology, and dermatology. There will be opportunity for a limited number of qualified special students to take work in these departments. Postgraduate courses in otolaryngology, ophthalmology, dermatology and radiology for a limited number of qualified students who are able to spend one or more years in study are continued during the summer quarter. In radiology, courses for shorter periods may be arranged. For further particulars, consult or address the dean or registrar.

Graduate School of Medicine of the Division of the Biological Sciences, University of Chicago, Fifty-Eighth Street and Ellis Avenue, Chicago.—Term extends from June 20 to August 26, offering to medical students the following courses: anatomy, hygiene and bacteriology, medicine, dermatology, neurology and neurosurgery, roentgenology, obstetrics and gynecology, pathology, pediatrics, pharmacology, physiology, surgery, clinical lectures, and clinical lectures in special fields. Address B. C. H. Harvey, M.D., dean.

Graduate School of Pediatrics, Children's Memorial Hospital, 707 Fullerton Avenue, Chicago.—One course in pediatrics, beginning August 1 and continuing for four weeks, will be offered graduates. The forenoons are taken up with medical pediatrics consisting of ward walks, outpatient and amphitheater clinics and demonstrations of special cardiac, syphilitic, neurologic, nephritis, infant and nutrition clinics, and of lectures on infant feeding, the newer phases of the contagious diseases of the blood, and so on. The afternoons are devoted to practical instructions in clinical pathology with special reference to laboratory methods of diagnosis; to x-ray demonstration; and to the specialties of surgery and orthopedics, and skin, eye, ear, nose and throat diseases. There is a weekly orthopedic ward walk and a weekly operative orthopedic clinic. A special course of one hour a week is given in pediatric technic covering lumbar and ventricular puncture, paracenteses and aspirations, intubation, collection of urine, blood typing, transfusion and the various methods of introducing fluids into the body. Eight didactic lectures are given in this course. Address all inquiries direct to the Graduate School.

#### IOWA

State University of Iowa College of Medicine, Iowa City.—The first term of the summer session will begin on June 13 and the second term on July 25. Courses are offered to graduates and undergraduates in anatomy, bacteriology, physiology, hygiene and preventive medicine. One freshman course in biochemistry will extend through both terms. Address Summer Session Office, Iowa City.

### KANSAS

University of Kansas School of Medicine, Lawrence.—On June 9, courses will be offered to graduates and students in anatomy, bacteriology, biochemistry, medicine and physiology. The course in medicine will be given at Kansas City. Address O. O. Stoland, Ph.D., Secretary of the Medical Faculty.

### LOUISIANA

Tulane University of Louisiana School of Medicine, 1430 Tulane Avenue, New Orleans.—During the early part of June, courses for medical students will be given in anatomy, embryology, histology and organology, neuro-anatomy and medicine. Address C. C. Bass, M.D., dean.

### MARYLAND

University of Maryland School of Medicine and College of Physicians and Surgeons, Lombard and Greene streets, Baltimore.—A three weeks' general review course will be offered to physicians in June. Registration is limited and preference will be given to physicians registered in Maryland. The course will consist of lectures, ward rounds, clinics, dispensary clinics, laboratory, therapeutic procedures, roentgen diagnosis, and electrocardiography. Address the Dean of the Medical School.

### MASSACHUSETTS

Boston University School of Medicine, 80 East Concord Street, Boston.—Offers a course in pharmacology from June 14 to July 23 for undergraduates. This course consists of systematic pharmacology, pharmacy, pharmaceutical chemistry, materia medica, toxicology, experimental pharmacology, conferences and reviews. Since the number of students is limited, arrangements should be made immediately. Address all communications to the Registrar.

Harvard University Medical School, 240 Longwood Avenue, Boston.—Offers an intensive five day course in genito-urinary surgery from July 11 to 15. This course is for graduates and consists of lectures, clinical lectures, demonstrations of cases and pathologic material, and operative clinics. On June 20 a graduate course in internal medicine will be offered, which will continue for six weeks. This course offers to properly qualified graduates in medicine an opportunity to receive instruction in the care of the sick, with particular reference to the diagnosis and treatment of common maladies. It is also designed to provide an adequate review of the more common problems that confront the general practitioner and the internist, with special attention to the recent advances in both diagnosis and therapeutics. Courses for graduates and undergraduates are offered throughout the summer in anatomy, physiology, biologic chemistry, bacteriology, pathology, preventive medicine and hygiene, pediatrics, medicine, roentgenology, diseases of the nervous system, surgery, anesthesia, proctology, genito-urinary surgery, orthopedic surgery, physical therapy, obstetrics, gynecology, dermatology and syphilology, ophthalmology, laryngology, and otology. Address Frank R. Ober, M.D., assistant dean.

Harvard University School of Public Health, 55 Van Dyke Street, Boston.—If individual work in some special field is desired, it is possible to arrange a program of study or research work by applying directly to the head of the department in which the work is to be done.

Massachusetts Institute of Technology, Cambridge.—Offers one course in general bacteriology. Address all inquiries direct to the school.

### MICHIGAN

University of Michigan Department of Post-Graduate Medicine, University Hospital, Ann Arbor.—Three courses will be offered from June 6-18 in proctology, gynecologic pathology, and a practitioners' course. Address the Department of Post-Graduate Medicine.

University of Michigan Medical School, Ann Arbor.—The summer session begins June 27 and ends August 19. Courses are open to practitioners of medicine, undergraduate students registered in recognized medical schools, and all persons qualified to pursue them to advantage. The undergraduate work will include: (1) all of the laboratory and some of the lecture courses of the first and second year; (2) some of the demonstration courses of the third year; (3) certain of the clinical courses of the senior year; (4) elective courses advantageous to medical students, technicians and others. Courses cover work in anatomy, bacteriology, dermatology and syphilology, internal medicine, neurology, obstetrics and gynecology, ophthalmology, otolaryngology, pathology, pediatrics, pharmacology, materia medica and therapeutics, physiologic chemistry, physiology, roentgenology and surgery. Address the Dean of the Medical School.

### MINNESOTA

University of Minnesota Medical School, Minneapolis.—The summer quarter is divided into two terms, the first extending from June 15 to July 23; the second, from July 25 to August 27. Students may attend either or both terms. All courses offered are open to physicians and medical students. Courses in anatomy, bacteriology, pathology, pharmacology, physiology, preventive medicine and public health, medicine, obstetrics and gynecology, ophthalmology and otolaryngology, pediatrics, radiology and surgery are given. Address Elias P. Lyon, M.D., dean.

### MISSOURI

St. Louis University School of Medicine, 1402 South Grand Boulevard, St. Louis.—From June 6 to July 30, courses for undergraduates will be offered in the different divisions of anatomy, bacteriology, biochemistry, pathology and physiology. For information, address the Director of the Summer Session.

### NEBRASKA

University of Nebraska College of Medicine, Forty-Second Street and Dewey Avenue, Omaha.—Courses in clinical pathology and physiology will be offered to medical students on June 4. A week's postgraduate course will be offered from June 6 to June 11. This course will be given under the auspices of the departments of obstetrics and pediatrics and will be confined largely to practical work in the wards and clinics. Address all communications to the Dean's office.

### NEW JERSEY

Physiatric Institute, Morristown.—Offers a one month course in July. The course is composed of lectures, laboratory and clinical work, and covers the subjects of diabetes, obesity, cardiorenal-vascular diseases and other metabolic disorders, and will probably include as a new feature the insulin treatment of tuberculosis. Address Frederick M. Allen, M.D., director.

### NEW YORK

Columbia University College of Physicians and Surgeons, 630 West One Hundred and Sixty-Eighth Street, New York.—A course in gastro-enterology will be offered from June 6 to July 27. This is a course of lectures designed for graduates in medicine desiring a working knowledge of the principles underlying the modern diagnosis and treatment of gastro-intestinal disorders. Address Willard C. Rappleye, M.D., dean.

University of Buffalo School of Medicine, 24 High Street, Buffalo. — Courses in systemic anatomy, and general pathology and pathologic histology for second year students will be given from July 5 to September 17. Address Edward W. Koch, M.D., dean.

University and Bellevue Hospital Medical College, Twenty-Sixth Street and First Avenue, New York.—Postgraduate courses will be offered in regional anesthesia and pediatrics during the early part of June. A graduate course is offered to qualified physicians who intend to specialize in dermatology. This course includes diagnosis and treatment of skin diseases, radiotherapy in skin diseases and roentgen therapy.

University of Rochester School of Medicine and Dentistry, Crittenden Boulevard, Rochester.—Offers a course for physicians in ophthalmology during the month of August. Address all inquiries direct to the school.

New York Polyclinic Medical School and Hospital, 341-353 West Fiftieth Street, New York.—Postgraduate courses will be offered for the general practitioner only, with the exception of special courses in pathology, roentgenology and refraction. Address F. H. Dillingham, M.D., medical executive officer.

New York Post-Graduate Medical School, Second Avenue at Twentieth Street, New York.—The following postgraduate courses will be offered to physicians during the summer: biochemistry, dermatology and syphilology, gynecology, lectures on refraction, bacteriology, pathology, pediatrics and urology. In addition to these the department of medicine will offer a four weeks' intensive course in cardiology, gastro-intestinal diseases, diseases of metabolism and pulmonary tuberculosis in September. A three weeks' course in applied immunology will be given from June 6 to June 25. Address all inquiries direct to the school.

School of Ophthalmology and Otology of the New York Eye and Ear Infirmary, Second Avenue, corner Thirteenth Street, New York.—One month courses will be offered during the summer months, as during the rest of the year, with the exception of refraction, which is a three months' course. Address the secretary.

Trudeau School of Tuberculosis, Saranac Lake.—The second section of the summer courses will be offered from June 14 to June 18. This section will include complications and differential diagnosis, clinics in laryngeal, aural and surgical tuberculosis, nontuberculous complications, institution organization and management, prophylaxis, surgical and laboratory technics, and the like. Address all inquiries to the secretary.

### OHIO

Ohio State University College of Medicine, Neil and Eleventh avenues, Columbus.—Bacteriology will be the only course offered during the summer. It will be offered by the department in either the Graduate School or the College of Arts and Sciences. Address all inquiries direct to the school.

Western Reserve University School of Medicine, 2109 Adelbert Road, Cleveland.—Offers an abridged course in gross anatomy to be given in June. Address all inquiries direct to the school.

### OKLAHOMA

University of Oklahoma School of Medicine, Third and Stiles streets, Oklahoma City.—Offers the following courses to undergraduates this summer: anatomy, bacteriology, biochemistry and pharmacology, histology and embryology, physiology and pathology. Address Lewis J. Moorman, M.D., dean.

### PENNSYLVANIA

University of Pennsylvania Graduate School of Medicine, Thirty-Sixth Street and Hamilton Walk, Philadelphia.—The following courses will be offered during the summer: clinical and sociological tuberculosis, cardiology, parasitology and tropical medicine, clinical gastro-enterology, allergy, diabetes mellitus, basal metabolism, clinical dermatology, neuro-anatomy, neurophysiology and neuropathology, neuro-otology, gynecology for the general practitioner, cystoscopy, selected office procedures in gynecology, ophthalmic operations, ocular refractions, slit lamp microscopy, otologic operations, rhinolaryngologic operations, correction of defects of speech, and clinical biochemistry. Address George H. Meeker, Ph.D., dean.

### TENNESSEE

University of Tennessee College of Medicine, 879 Madison Avenue, Memphis.—All the courses of the curriculum will be offered during the summer quarter. Address O. W. Hyman, Ph.D., dean.

Vanderbilt University School of Medicine, Twenty-First and Edgehill, Nashville.—Offers short courses for postgraduates in medicine this summer. Address Waller S. Leathers, M.D., dean.

TEXAS

Baylor University College of Medicine, 810 College Avenue, Dallas.—The following courses will be offered from June 13 to August 1: physiologic chemistry, histology, bacteriology and neuro-anatomy. Address W. H. Moursund, M.D., dean.

VIRGINIA

Medical College of Virginia, Twelfth and Clay streets, Richmond. —A two weeks' course has been arranged for the Negro practitioners of the state of Virginia. This course will be held in connection with the St. Philip Hospital, which is under the supervision of the medical school, and will be conducted during the last two weeks in June. Address Lee E. Sutton, Jr., M.D., dean.

University of Virginia Department of Medicine, Charlottesville. —All of the medical science courses will be given during the first term of the summer quarter beginning on June 20 and ending July 30. The following courses are offered primarily for medical students who are deficient in these subjects and desire to make a review: histology, embryology, anatomy, biochemistry, physiology, bacteriology and pharmacology. Address James C. Flippin, M.D., dean.

WISCONSIN

University of Wisconsin Medical School, 412 North Charter Street, Madison.—Summer quarter begins June 27 and ends August 5, offering courses in histology and organology, embryology, three courses in anatomy, two courses in bacteriology, fourth year medicine and surgery open only to Wisconsin students, two courses in pharmacology, physiologic chemistry, and advanced physiology and research. Address all inquiries direct to the school.

---

# Book Notices

**The Structure and Composition of Foods.** By Andrew L. Winton, Ph.D., and Kate Barber Winton, Ph.D. Volume I: Cereals, Starch, Oil Seeds, Nuts, Oils, Forage Plants. Cloth. Price, $8.50. Pp. 710, with 274 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1932.

This is the first of the three volumes of a comprehensive work in the English language comparable with, yet differing from, the voluminous works in German and French, giving the results on the composition and macroscopic and microscopic structure of a great variety of products scattered through numerous journals and publications. The products described, chiefly natural or obtained by mechanical separation such as milling or pressing, or operations involving simple chemical changes, cover a broad geographic range—oriental and occidental, temperate and tropical. The products are classified according to economic use. This volume includes a short introduction explanatory of general technical terms, plan of the volumes and information to aid in the interpretation of data; part I treats of the true cereals, starch seeds and weed seeds; part II, of oil seeds, oil nuts and weed seeds free of starch; part III, of plants grown for green forage or hay and grouped under the three headings of grasses, legumes and cacti. The entire work promises to be a descriptive reference compendium of great usefulness to all seeking information on a vast variety of well known and little known foods. The American academic and industrial reference libraries have need for this practical contribution.

**Exercise and Its Physiology.** By Adrian Gordon Gould, Ph.B., M.D., Assistant Medical Adviser and Assistant Professor of Hygiene in Cornell University, and Joseph A. Dye, A.B., Ph.D., Assistant Professor of Physiology in Cornell University. Cloth. Price, $3. Pp. 434, with 56 illustrations. New York: A. S. Barnes & Company, Inc., 1932.

The vast amount of research on the physiology of exercise and rest in recent years has prompted the publication of several books on the subject. The authors here review the accumulated material and present their conclusions "in nontechnical language" so as to make the book especially valuable for students of physical education and for students and teachers of physiology. Where the evidence is still controversial, they present both points of view. The book is divided into twenty-six chapters, which consider the mechanisms of movement, the physiologic properties of muscle, the nature of fatigue and of recovery, and the physiology of the blood and respiration during exercise. Four chapters concern the circulation and its adaptation to activity. The volume concludes with a consideration of the second wind and of the effects of training on exercise and activity.

Although the authors have attempted to make their presentation nontechnical, it certainly could be followed by few except those who have had early college physiology: for example, the following sentence: "There are two possible explanations for the increased glycogenolysis following splanchnic stimulation, first, that the hepatic branches of these nerves when stimulated effect the breakdown of glycogen directly (*nervous* or *direct*), and second, that the suprarenal branches produce an increased output of adrenin which in turn effects the glycogenolysis (*hormonal* or *indirect*)." Notwithstanding this minor criticism, the book is an exceedingly useful summary of current knowledge in its field.

**Die experimentellen und klinischen Grundlagen der Therapie mit Calciumsalzen.** Von Dr. Eugen Baráth, Assistent an der III. med. Klinik der Kgl. Pázmány Péter Universität in Budapest. Hefte des Collegium Hungaricum in Wien. X. Paper. Pp. 117. Budapest: Königl. Ungar. Universitätsdruckerei, 1931.

In an excellent presentation, systematic in arrangement and characterized by conciseness and clarity, the author discusses the rôle of calcium in its direct application to specific problems and its relationship to the general problem of ionic phenomena and physicochemical problems. Throughout the entire discussion he maintains the attitude of a detached observer carefully evaluating the facts and interpretations and at no time losing himself to fall into fanciful speculations. The work is divided into four parts. In the first part the author discusses ionic phenomena and the cell, the effect of calcium on the perfused organ, and calcium metabolism in all its phases. The second portion deals with the pharmacology of calcium salts and an analysis of the experimental and therapeutic use of calcium compounds. The third section deals with the clinical use of calcium in acute hemorrhage, tetany, asthmatic conditions and intoxications. The last chapter presents an interesting survey of the significance of ionic therapy in the light of physical chemistry. The bibliography is concise and carefully selected. This work presents the subject in a short discussion and, despite the large number of papers on the subject, no important fact has been omitted. It will serve a useful purpose for those interested in calcium therapy.

**The Medical Value of Psychoanalysis.** By Franz Alexander, M.D. Cloth. Price, $2.75. Pp. 247, with 5 illustrations. New York: W. W. Norton & Company, 1932.

The Journal published, some months ago, a Harvey lecture on psychoanalysis by Dr. Alexander. The present volume includes this chapter, together with an expansion of its views, in book form. Dr. Alexander is a medical psychoanalyst, primarily a teacher and an investigator, but also a successful practitioner. He writes directly and does not confuse his readers with much of the special jargon that has attached itself to this field. The book includes five chapters, on psychoanalysis and medicine, the present status of psychoanalysis as a theoretical and therapeutic system, critical considerations on the psychoanalytic treatment of psychoses, psychogenic factors in organic diseases, and psychoanalysis in medical education. Dr. Alexander defends the view that separation of the psychologic and somatic approaches to understanding of disease is artificial and obsolete. He recognizes the resentment of Sigmund Freud at the refusal of medicine to appreciate his life work, but he feels that the proper place for psychoanalysis is in the medical curriculum and that it must inevitably become a part of medical study. Indeed, he concludes with an outline of the manner in which the teaching of psychoanalysis should be embodied in the medical curriculum.

**Anleitung und Indikationen für Bestrahlungen mit der Quarzlampe „Künstliche Höhensonne" mit Berücksichtigung der leuchtenden Wärmestrahlen.** Von Geh. Sanitätsrat Dr. Hugo Bach. Unter Mitwirkung von Dr. Ferdinand Rohr, Dirig. Arzt des Kinderkrankenhauses „zum Kind von Brabant," Kassel. Twenty-second-twenty-third edition. Paper. Price, 8.40 marks. Pp. 258, with 41 illustrations. Leipzig: Curt Kabitzsch, 1931.

This is a reasonably complete dissertation on the clinical studies of light therapy, principally in relation to the quartz lamp and aids such as heat lamps. It especially avoids reference to carbon arc and other light sources, which have been found to play a part in treatment of disease, as well as the mercury quartz lamp. It goes into details as to the technic and mode of action, so far as is known, of the light emitted by the quartz lamp. Dosage and meters for measuring are considered. The indications in general medicine, surgery, children's diseases, skin diseases, gynecology, and diseases of the eye, ear, nose, throat and teeth are taken up. The illustrations are appropriate but are mostly repetitions. There are many claims made in the book which would not withhold critical analysis. The author makes practically no mention of light authorities outside of Germany, but ample references are given to German authorities. Particular claims are made for light in certain forms of tuberculosis, such as the larynx and the ears, which do not agree with ideas held on the subject in this country. Special applicators and modes of irradiation are emphasized with only personal clinical impressions to back them up. With this understanding, the book can be considered a valuable addition and one that covers the subject satisfactorily.

**The Social and Ethical Significance of Nursing: A Series of Addresses.** By Annie Warburton Goodrich, Dean, Yale University School of Nursing. Fabrikoid. Price, $3. Pp. 401, with 13 illustrations. New York: Macmillan Company, 1932.

Dean Goodrich has prepared a valuable treatise on the ethical significance of nursing, and added greatly to the cause of the sound education of the nurse. She has shown clearly that "from the standpoint of sustained interest and creative opportunity few activities offer as much as nursing, but such returns demand the insight and resourcefulness which are the rewards of a liberal education." In speaking of the nurse and the hospital she holds up the standard that all nurse educators of today should keep in mind: "No sounder foundation for practice was ever laid for a profession than that for nursing through its provisions for constant and close association with the patients in the wards of the hospital. Whatever the changes in the curriculum through the evolution in the medical sciences, the immeasurable values of the clinical content as expressed in the hospital service must not be lost. The unuttered but insistent emphasis on the value of every life leaves an enduring impress, to the influence of which must be attributed the unceasing effort to create for each the best environment." In "The Nurse and the World" she pictures to the girls who are studying nursing that "its doors are open to all who need its services . . . whose contribution to future generations cannot be measured. . . . The essential thing is that each individual should find satisfaction in the chosen pursuit that ensures the best he has to give, devotion in its fullest sense . . . to insure, with understanding of the project, as a co-laborer not as a machine, the best that can be given."

**The Experimental Study of Reading.** By M. D. Vernon, M.A. Cloth. Price, $3. Pp. 190, with illustrations. New York: The Macmillan Company; London: Cambridge University Press, 1931.

Human beings vary greatly in their ability to read. Some read rapidly and absorb what they read; others read slowly and get little from their reading. This volume gives a concise account of the author's own experiments, particularly from the point of view of the action of the ocular tissues in the reading process. He discusses the movements of the eye and particularly the employment of such movements in reading, following this with a special study of the reading of children and finally of the relationship of typography to reading. In mature adult reading, regular and rhythmic backward and forward movements develop, later alternating with fixation pauses. These movements are habitual. The movements are interfered with by any species of mental struggle or conflict. Thus the ability to read rapidly may be learned and it is important to stress familiarity, interest and associated fact for competent reading.

**The Social Life of Monkeys and Apes.** By S. Zuckerman, Anatomist to the Zoological Society of London. Cloth. Price, $3.75. Pp. 356, with 24 illustrations. New York: Harcourt, Brace & Company, 1932.

Monkey society is based on dominance. The strongest monkey gets the most food, the strongest male gets the most wives. Monkeys apparently can learn, but the vast majority of their behavior is instinctive. The author, through many kinds of observations of apes and of monkeys both in captivity and wild, comes to the conclusion that the difference between the apes and man is the difference between physiology and culture. The work is extraordinarily interesting and reveals a basis for much human behavior that may be apelike but seems reasonable. The volume concludes with an excellent bibliography of more than 100 references, an index of monkey types, and an index of authors and subjects.

**Equinococosis: Quistes hidatídicos.** Por el Dr. D. Ricardo Lozano, catedrático de clinica quirúrgica de la Facultad de medicina de Zaragoza. Con la colaboración del Dr. D. Ricardo Lozano, Hijo, auxiliar de anatomia topográfica y operaciones en la Facultad de medicina de Zaragoza. Paper. Price, 8 pesetas. Pp. 153, with 12 illustrations. Madrid: Casa Editorial Bailly-Bailliere, S. A., 1931.

Echinococcus disease is endemic in Zaragoza as the result of its high incidence (from 20 to 30 per cent) in animals in the slaughter houses. Human infection is relatively frequent. Any organ of the body may be attacked, but hydatid cysts of the liver are the usual result. The authors emphasize a characteristic trembling of such echinococcus cysts, which persists for a short time after percussion. This is helpful in differentiating echinococcus from other diseases of the liver. The hydatid cysts in the liver are large solitary cysts with no compensatory hypertrophy of the uninvolved liver. Secondary infection, unaccompanied by septicemia, is a frequent complication of the cyst. The choice of treatment is marsupialization. Infection of the lungs occurs in about 8 per cent of human echinococcus infection. The right lung is more often affected than the left, and the authors suggest that this may result from direct extension from the liver. With more roentgenologic examinations, small foci clinically latent may be observed in the future. Of the organs more rarely involved, there is a great deal of interest attached to the thyroid gland: younger persons are more often attacked than older persons. This small volume is highly interesting and gives the reader a comprehensive review of echinococcus disease.

**Rational Pharmaceutical Treatment of Common Skin Diseases.** By Herman Goodman, B.S., M.D. Cloth. Price, $10. Pp. 350, with 72 illustrations. New York: Medical Lay Press, 1932.

Eleven groups include nearly three fifths of all the diagnoses made of patients with skin disease. As stated in an editorial in The Journal some years ago, every practitioner should become familiar with eczema, acne, scabies, psoriasis, seborrhea, impetigo, urticaria, dermatitis venenata, tinea, alopecia, pediculosis and pruritus. Dr. Goodman in this volume briefly considers the anatomy of the skin, methods of examination, bathing and diet and then discusses the treatment of the diseases of the skin according to the groups mentioned. The book is simply written and is planned particularly for the general practitioner. In view of the close relationship of allergy to disorders of the skin, the author includes a discussion of elimination diets not only for adults but also for children of various ages. The illustrations are printed on special stock; the text itself with large type and on good paper. There are numerous citations of useful prescriptions, so that the book is probably one of the most practical handbooks for general practitioners thus far made available.

# Medicolegal

## Liability for Roentgen Burn

*(Casenburg v. Lewis (Tenn.), 40 S. W. (2d) 1038)*

In 1918, Mrs. Lewis was operated on for the removal of an abdominal tumor. After the incision had been made, it was deemed inadvisable to remove the growth; according to one physician, because it was malignant, and according to another, because of adhesions to vital organs. The incision was closed, and after it had healed Mrs. Lewis was sent to the physician defendant for roentgen treatment. From the first treatment in 1918 up to some time prior to May 5, 1924, he administered 160 treatments, without injury. On May 5, 1924, the roentgen ray was again applied, in equal dosage to the abdomen and back, and a third degree burn of the abdomen followed, covering a space approximately 7 inches by 9 inches and extending "to the underlying abdominal membrane." Mrs. Lewis sued the physician defendant. She died, however, Jan. 14, 1926, and the cause was prosecuted by her administrator. The immediate cause of her death, it was testified, was appendicitis, superinduced by the roentgen burn. The burn made it impossible to operate, because the incision would have extended through the burned tissue, without possibility of healing.

At the first trial, the court directed a verdict for the physician defendant. On appeal by the plaintiff the court of appeals reversed the cause and remanded it for another trial, and the Supreme Court of Tennessee affirmed that action.[1] The second trial resulted in a judgment for the plaintiff. The court of appeals, however, reversed that judgment and again remanded the case to the trial court, because of the failure of that court to direct a verdict in favor of the physician defendant. The plaintiff a second time appealed to the Supreme Court of Tennessee, which then affirmed the judgment of the trial court in his favor, subject to a reduction in the amount of the judgment.

If the instrumentality that produces an injury, said the Supreme Court, is under the exclusive control of the defendant, and if an injury would not ordinarily result if due care is exercised, the doctrine of res ipsa loquitur applies and raises an inference of negligence on the part of the defendant. That inference becomes conclusive unless rebutted by countervailing evidence. When an effort is made to rebut this inference by opposing evidence, the weight of the inference as well as the weight of the explanatory evidence must be determined by the jury, unless uncontradicted explanatory evidence excludes the inference that the injury resulted from want of ordinary care. The trial court, therefore, rightly allowed this case to go to the jury.

At the trial, an undiscoverable idiosyncrasy on the part of the patient, superinduced by the cumulative effect of past treatments, producing endarteritis, was alleged by way of defense; also the negligent use of scarlet red on the itching surface of the abdomen. The physician defendant and other witnesses testified that the roentgen apparatus used was such as was in common use by other physicians, that it was properly used, and that the roentgen ray was applied properly in respect to both time and intensity in the course of the treatment of May 5, 1924, and of all other treatments. In the opinion of the physician defendant, the injury to the decedent was unavoidable.

A medical witness testified that third degree burns are unusual and attributed them to the following causes: (1) excessive dosage, caused by failure of the roentgenologist to use proper filterage, or by excessive exposure, or by increased intensity of the ray; (2) idiosyncrasy on the part of the patient; (3) failure of the operator to observe the patient so as to determine whether the cumulative effects of preceding treatments have approached the danger point. The court of appeals, said the Supreme Court, concluded that the physician defendant was confronted with the necessity of determining whether he should let his patient die of the malignant growth for which he had been treating her or continue the treatment to arrest the growth, and the court of appeals held that for the consequences of the exercise of his judgment in continuing the treatment after 160 antecedent treatments he was not liable. But, said the Supreme Court, while it is the physician's privilege to decide between one of two or more courses in the treatment of his patients, and while he cannot be held responsible for an erroneous exercise of his judgment, the rule is subject to the limitation that before exercising his judgment the physician must learn by proper examination the facts and circumstances on which a reasonable exercise of judgment may rest.

The defendant knew that he had administered 160 treatments. The cumulative effect of those treatments was or should have been known to him. He should have known, too, the means of ascertaining when an additional treatment would be hazardous to the patient. All physicians agreed in their testimony that the cumulative effect of the roentgen ray is ordinarily disclosed by dryness and pigmentation of the skin, thus enabling the roentgenologist to discover the danger of an additional treatment by superficial or surface symptoms. They agreed, too, that the cumulative effects of the roentgen ray are not always visible in endarteritis. It was testified that when endarteritis, or the blood change indicative of it, is not visible on the surface, the condition may be discovered by a blood count. It was testified further that without cumulative effects visible or ascertainable on reasonable examination, the roentgen-ray dosage, if properly administered, could not produce a third degree burn.

The physician defendant testified that when he administered the last treatment he examined the skin, both on the back and on the abdomen, and that there was no pigmentation or dryness, but it was in evidence that endarteritis would not be apparent to a roentgenologist through an examination of the skin. Superficial symptoms, it was shown, cannot always be relied on to reveal the danger that all experts agree may result from cumulative treatment. Hence the necessity for resort to additional methods of diagnosis, such as the blood count. The failure of the physician defendant in this case to resort to a blood count to determine whether danger existed was not a mere error of judgment; it was the omission to do what reasonable prudence would suggest, especially where the consequence of previous treatments might lead the roentgenologist reasonably to apprehend the danger of an additional treatment causing a third degree burn. After 160 roentgen treatments without injurious effect, the theory of idiosyncrasy on the part of the patient was incredible.

There was evidence that scarlet red was used on the patient's abdomen at some time after the last roentgen treatment. Physicians agreed that its use within a short time after the treatment would convert a first degree burn into a third degree burn, but they said that two weeks after the treatment the use of scarlet red would be harmless and might be beneficial. There was no evidence to show when or by whom the scarlet red was applied. Thirteen days after the treatment on May 5, a physician examined the burn and no scarlet red had been applied at that time. At his visit twenty-six days after the treatment referred to, he found that scarlet red had been applied. If scarlet red was applied, it must have been done after the danger of its use had passed.

All the explanatory evidence taken together does not destroy the weight of the inference of negligence, arising from the doctrine of res ipsa loquitur. The weight of the inference, as well as the weight of the explanatory evidence, was therefore a matter for determination by the jury.

Maine Medical Association, Rangeley, June 16-18. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.

Massachusetts Medical Society, Boston, June 8-10. Dr. Walter L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

National Tuberculosis Association, Colorado Springs, June 6-9. Dr. Charles J. Hatfield, 7th and Lombard Streets, Philadelphia, Secretary.

New Jersey, Medical Society of, Atlantic City, June 15-17. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.

North Dakota State Medical Association, Grand Forks, June 1-2. Dr. Albert W. Skelsey, 18 Broadway, Fargo, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

Rhode Island Medical Society, Providence, June 2. Dr. J. W. Leech, 369 Broad Street, Providence, Secretary.

South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Modifications of Differential Stains with Especial Reference to Trichromic Stain of Cajal. R. Castroviejo, New York.—p. 135.

**Rhinosporidium Seeberi in Nasal Polypus.**—Graham reports a case of rhinosporidial infection in a nasal polypus. The patient was a Negro boy, aged 12 years, born in Georgia and resident since the age of 4 in a small coal-mining village in Alabama. The source of the infection is unknown, no other similar condition having been observed in the community for at least ten years. The case illustrates the remarkable discontinuity of the infection, of which more than forty known cases reported during the past thirty years have been observed in three widely separated localities, India, Argentina and the United States. Preoperative diagnosis should be made without particular difficulty through recognition of the characteristic spores in the nasal secretions.

**Glycosuria and Glycemic Tolerance Curve.**—Herrmann enumerates the more important diagnostic criteria to be considered in using the dextrose tolerance test, thus: The blood sugar should never be determined after fasting or a dextrose tolerance test done on any patient until that patient has been on an ordinary mixed diet, unrestricted as to carbohydrate intake, for some days or weeks. A reliable and accurate arterial method should be used, and within the first hour samples should be taken, preferably at ten, twenty and thirty minutes, since the peak of the rise for the most part occurs at these periods. The normal fasting blood sugar, both venous and arterial, should not exceed 0.11 Gm. per hundred cubic centimeters by any method used, except in people more than 40 years of age or in those having febrile diseases, anemia, cerebral hemorrhage or hyperthyroidism. The tolerance curve should be determined by using 1 Gm. of dextrose per kilogram of body weight after a twelve hour fast, the dextrose being given by mouth in a 10 per cent solution. Under these conditions in arterial blood the normal tolerance curve should not rise higher than 0.2 Gm. per hundred cubic centimeters and the curve should fall to 0.11 Gm. or below at the end of two hours. Threshold determinations should be made in any case in which the curve shows any abnormality in the presence of glycosuria, so that the type of glycosuria may be tentatively classified. A fasting blood sugar of more than 0.11 Gm. on any occasion is almost undoubtedly indicative of diabetes. One should not be satisfied with a single fasting sugar. In a doubtful case, repeated fasting sugar determinations should be done over a period of months. All persons showing a normal fasting sugar with a pronounced hyperglycemic curve of long duration should be suspected of diabetes and put under observation. In abnormal cases of doubtful origin the fermentation or phenylhydrazine test should be used in the determination of type for the excreted sugar. In addition one must (*a*) take a careful family history for possible glycosuria; (*b*) eliminate diseases, other than diabetes, that may cause disturbance of carbohydrate metabolism; (*c*) remember that long periods of observations, even up to forty years, seem to show that there is no transition in the same individual from nondiabetic glycosuria in any of five classes discussed by the author to true diabetes mellitus, and in cases without glycosuria, tolerance curves higher than normal do not necessarily indicate diabetes.

Chronic Adult Idiopathic Tetany: Report of Case. S. S. Leopold and L. Jonas, Philadelphia.—p. 418.

**Infective Asthma.**—Cooke believes that asthma of infective origin is subject to hereditary influence. This, of course, only proves that asthma, whether of the infective or the skin-sensitive type, is the offspring of hereditary influences. But the facts that 15 per cent of all asthmas are combined sensitization and infective types, that skin-sensitive allergies are frequent in the antecedents of infective asthma and that the opposite condition also obtains, all lend support to the view that the two types may be regarded as of the same nature. Eosinophilia may be regarded as an allergic phenomenon. Experimentally it is produced only under conditions that are regarded as favoring sensitization. Local eosinophilia of histogenous origin is believed to be shown. Eosinophilia is as frequent in asthma of infective origin as in that of the skin-sensitive type. Infective asthma may be regarded as an allergic reaction quite as properly as is the skin-sensitive type, although the immunologic reactions in the two forms are not identical.

**Pulmonary Gas Absorption in Bronchial Obstruction.**—Coryllos and Birnbaum have devised experimental methods which give evidence that, when a bronchus is completely obstructed, the entrapped alveolar air rapidly undergoes qualitative and quantitative changes as determined by successive gas analyses. Qualitatively, the percentages and partial pressures of the gases comprising the alveolar air tend to, but never quite, reach an equilibrium with the gases of venous blood. Quantitatively, the entrapped alveolar gases pass through the respiratory membrane into the blood circulating in the perialveolar capillaries until complete airlessness of the involved area is produced. The mechanism of production of atelectasis in the compressed lung (pneumothorax, pleural exudate, intrathoracic tumors, and so on) is exactly the same as in bronchial obstruction. Besides the gases of the air, diffusion of other gases was studied by introducing them into a lung previously rendered atelectatic. The different gases used in these experiments were: (1) active gases, oxygen and carbon dioxide; (2) neutral gases, hydrogen, nitrogen and helium, and (3) anesthetic gases or vapors, ether, ethyl chloride; nitrous oxide and ethylene. A new experimental method was devised which allows direct vision of the pulmonary changes occurring during the experiment. Nitrogen in the respiratory air plays the part of a "mechanical buffer," retarding the absorption of more diffusible and more soluble gases. This experimental work has allowed the formation of a theory on the mechanism of atelectasis based on the physiology of exchange of gases in the lung.

**Pathology of Rheumatic Pneumonia.**—Gouley and Eiman present nine cases of acute rheumatic fever with reference to the pathologic changes in the lungs. Eight of these showed an acute inflammation of lung tissue with consolidation; the ninth showed pleurisy with subacute lung involvement. All of them were associated with acute rheumatic heart disease. The inflammatory pulmonary reaction consisted of an interstitial perivascular exudate of large endothelioid cells, identical in morphology with those found in rheumatic heart lesions and considered pathognomonic of rheumatic fever. Hemorrhage and fibrinous exudate were prominent features. The authors therefore consider that in many virulent cases a characteristic rheumatic pneumonia is to be found.

**Abdominal Crises in Sickle Cell Anemia.**—Leivy and Schnabel report three cases of sickle cell anemia to illustrate the critical abdominal attacks that may occur in this disease. Current explanations of such paroxysmal abdominal pains as found in the literature are discussed and other explanations not previously suggested are examined. None of these, whether old or new, are thought to explain adequately the abdominal crises under consideration. It is quite possible that a single explanation may not apply for all of the critical abdominal episodes as they occur in sickle cell anemia. On the basis of marked bony changes in the vertebrae of the authors' first case, they suggest root pains as a cause for the paroxysmal crises of pain and rigidity.

What Is Health News? G F. Wright, Montreal—p. 292
Intradermal Method of Virulence Testing of Corynebacterium Diphtheriae. J. R. Wells, St. Louis.—p. 308.

**Epidemiology of Diphtheria.**—According to Godfrey, the injection of from 50 to 70 per cent of children aged more than 5 years with three doses of toxin-antitoxin has failed in numerous instances to produce any marked effect on the diphtheria incidence of a community. The immunization of 30 per cent or more of children in the age group under 5 years in addition to more than 50 per cent of children aged from 5 to 9 years has in several instances produced an immediate and striking decline in the diphtheria rate of the community as a whole. The promptness of this seeming response suggests that a high degree of immunity is quickly acquired by a majority of those given three doses of toxin-antitoxin. It is a matter probably of a few weeks rather than of several months. In only two instances known to the author has a community that had attained 30 per cent immunization of the age group under 5 years suffered even a moderate epidemic. It is possible that immunization of the age group under 5 years should not be uniformly distributed through the community but should be largely concentrated in sections of highest prevalence if diphtheria is prevalent; if not, then in the congested areas. The study is presented as a working hypothesis, worthy of trial as a means of quickly ridding a community of epidemic diphtheria. More data from more varied sources are necessary to establish its validity. To this end, uniformity in the tabulation of immunization statistics is a necessity. The Committee on Administrative Practice and all health departments should adopt the standard age grouping in their tables, should classify immunizations by single years of age up to 10 years and should annually or oftener so tabulate their material as to show the present status. It is suggested that the unrecognized case rather than the healthy carrier is responsible for the occult infections occurring during epidemics or periods of high prevalence. It seems not improbable that many mild nasal cases would be discovered if diligently sought. Such cases are the ones most likely to spread infection. Finally, it should be clearly understood that this presentment is in no sense a plea for any community to stop work when it has attained a 30 per cent immunity. That figure may be much too low. Active immunization, like antitoxin, was introduced on a wholesale scale during a period when diphtheria was receding from a period of high epidemicity. It is the more difficult, therefore, to measure its effect. The immunity conferred may not suffice for an organism of greater invasiveness, virulence and pathogenicity. In any event, the only reasonably sure production for the individual is individual immunization.

**Bacteriologic Analysis of Shigella Paradysenteriae Sonne.**—Welch and Mickle report nine cases of diarrheal disease caused by Shigella paradysenteriae Sonne. A detailed, morphologic, physiologic and serologic study is presented. The American Type Collection Cultures Shigella paradysenteriae Sonne 31 and Metadysenteroides 4086 appear to be identical in their fermentative and serologic reactions. Shigella dispar 29 appears to be distinct from Shigella paradysenteriae Sonne in its serologic and fermentative characteristics. A serologic relationship between Shigella paradysenteriae Flexner and Shigella dispar is demonstrated by direct agglutination and by agglutinin absorption. Further emphasis is placed on the significance of Shigella paradysenteriae Sonne as a cause of diarrheal disease in this country.

*Summary of Study of Types of Tubercle Bacilli Isolated from Human Lesions. R. M. Price, Toronto.—p. 383.
Dynamic Bronchial Tree. C. C. Macklin, London, Canada.—p. 393.

**Metaphen-in-Oil in Pulmonary Cavitation.**—Jacobs believes that collapse therapy and thoracoplasty constitute the only rational treatment in the management of pulmonary cavitation. In the far advanced and inoperable cases, external drainage should be encouraged. This can be accomplished by intrapulmonary medication with different drugs dissolved in oil, which should be followed by postural drainage. With this method, the expectoration is mechanically facilitated and reduced. The cough is diminished and the temperature, pulse and respiration are greatly improved. Thus far in the author's experience, metaphen-in-oil, 1:5,000 solution, has proved to be the best available agent. It has antiseptic properties, and it is nontoxic and nonirritating.

**Use of Artificial Pneumothorax Apparatus During Thoracoplasty.**—Haight reports a case of tuberculous empyema with pneumothorax, in which an increase in the intrapleural pressure during the second-stage thoracoplasty resulted in marked respiratory and circulatory embarrassment. Prompt lowering of the intrapleural pressure by withdrawal of air from the pleural cavity relieved the condition, which might otherwise have proved fatal. The routine use of the pneumothorax apparatus during thoracoplasty in cases of closed pneumothorax is suggested. By regulation of the intrapleural pressure during the operation, it is possible to obviate a shift of the mediastinum and consequent respiratory and circulatory embarrassment. Furthermore, on completion of the operation, an optimal collapse of the chest wall may be attained by decreasing the pneumothorax as desired or by abolishing it entirely.

**Laboratory Tests for Tubercle Bacilli by Culture Methods.**—Norton and his associates describe experiments whose results are in agreement with those of previous workers, who maintain the superiority of cultures over animals in identifying tubercle bacilli in material sent to the laboratory for examination. Culture methods produce more positive results, save expense, usually save time, and allow the bacteriologist to proceed at once with further tests if they are desired. Growths were obtained from 137 specimens in which tubercle bacilli were not found on direct examination, in the average time of thirty days, with a minimum of twelve and a maximum of seventy-seven days. No significance is attached to the slight differences found in the various groups of specimens. The use of not less than four tubes and two different mediums are recommended. In the authors' hands, the Petragagni medium was somewhat superior to the modified Petroff medium employed.

**Types of Tubercle Bacilli Isolated from Human Lesions.**—Price reports that of 220 patients in the juvenile group suffering from some form of tuberculosis, 190 proved infected with the human type and thirty patients were infected with the bovine type of the tubercle bacillus. In the majority of instances in which the human type of the tubercle bacillus was isolated, there was a known history of contact with open pulmonary tuberculosis. Contact was usually close, the patient being exposed to tuberculous parents, grandparents, guardians, near relatives, and occasionally individuals sharing the home with the family. In some of the cases, two or more children in the family proved infected. Physical or roentgen examination or both showed evidence of tracheobronchial or pulmonary disease, the evidence pointing to the respiratory route of infection. In thirty cases in the series, the youngest an infant 5 months of age and the oldest a girl of 12 years, the infection was caused by the bovine type of the tubercle bacillus. Without exception, the children harboring an infection with the bovine tubercle bacillus have come from parts in the province of Ontario where pasteurization of milk was not carried out. The history invariably revealed the fact that the child had been fed on raw milk. It was possible on a number of occasions to demonstrate virulent tubercle bacilli in the milk consumed by the child and in the cattle responsible for the transmission of the disease to the human host and thus bring forward the indubitable evidence of the source of the childhood infection. On the basis of his observations, the author draws the following conclusions: 1. Bovine tuberculosis is an almost negligible factor in adult human infection. 2. The bovine tubercle bacillus is a factor of considerable importance in childhood tuberculosis. Thirteen and six-tenths per cent of nonpulmonary tuberculosis, leading to disablement, operation and necessitating prolonged and costly treatment, with doubtful results at the outcome, is caused by the bovine tubercle bacillus. 3. The disease is milk-borne. 4. Bovine tuberculosis is preventable and can be controlled by the effective pasteurization of milk. The truth of this statement is forcibly brought out in the fact that in the city of Toronto, where pasteurization of milk is compulsory and has been rigidly enforced since 1915, not a single case of bovine infection has been encountered in the group of children brought up on the pasteurized milk of the district (1915 to 1930).

**Irradiation of Mammary Cancer.**—Lee and his associates state that preoperative external irradiation for mammary carcinoma is of value, as is proved by (1) the occasional regression of tumors so treated; (2) the histologic changes produced, and (3) the better clinical end-results. An efficient devitalizing dose cannot be delivered by external irradiation alone. To deliver an efficient dose one must use interstitial irradiation. The tissue dose delivered to the tumor should be measured and expressed in skin erythema units. This dose should be prescribed. Tables prepared in the physical department enable the clinician to translate into terms of skin erythema units the tissue dose delivered, whether by external or interstitial irradiation. The universal tissue dosage necessary to effect destruction of a radioresistant mammary cancer approximates twelve skin erythema doses. The safest procedure is to treat all patients with mammary cancers with the same sufficient dose, because (1) radiosensitivity cannot always be determined before operation, and (2) the same tumor may contain radioresistant and radiosensitive areas. Mammary cancers vary markedly with respect to radiosensitivity. The mammary gland will tolerate safely an enormous dose of interstitial irradiation. The possible menace of dissemination of the disease by the method of interstitial irradiation is considered. The authors have not seen evidence of such a dissemination in this series. Preliminary external irradiation lessens this possibility. All preoperative irradiation should be given within three weeks or less time. Six weeks should elapse following interstitial irradiation before radical amputation is performed. An interval of six weeks is necessary, because after this interval (1) the effects of irradiation are complete; (2) complete destruction of the tumor is accomplished, and (3) wound healing is unimpaired. The authors' present treatment for primary operable mammary cancer is external irradiation, then interstitial irradiation and finally radical amputation six weeks later. The axilla is irradiated by (1) preoperative roentgen rays or radium element pack, followed by (2) interstitial gold-filtered radon distributed along the lymph-node-bearing areas. The pathologic changes produced in mammary cancer by external irradiation are mainly due to vascular effects. There are moderate hydropic swelling of the tumor cells, moderate atrophic degeneration, marked collagen swelling, productive arteritis with thrombosis and calcific deposits in the vessel walls and productive fibrosis. The changes produced by interstitial irradiation are mainly direct effects on the tumor tissue, namely, ballooning degeneration, hydropic swelling, giant nuclei and atypical degenerative mitoses, a tendency toward squamous metaplasia followed by sloughing, hemorrhage, infiltration by fatty macrophages with ensuing extensive calcific deposits, often acute capillary necrosis with resultant tumor necrosis, squamous metaplasia of normal adjacent lobules in the breast, collagen swelling, productive fibrosis and late atrophy of the residual tumor.

**Operations on Superior Pole of Thyroid.**—Roeder enumerates thus the significant complications that may occur during the removal of the superior pole of a goitrous thyroid: (1) injuries to the inferior and superior laryngeal branches of the vagus, producing (*a*) partial or complete loss of voice, (*b*) obstruction to inspiration, (*c*) aspiration of ingested fluids into the bronchi, (*d*) loss of sensation to the mucosa of the larynx, and (*e*) referred pain to the lower portion of the pinna through the "vagopinna reflex"; (2) referred pain to the mandibular teeth through the "thyromandibular reflex"; (3) paralysis of the soft palate; (4) referred somatic pain through any or all of the first four cervical spinal sensory nerves; (5) hemorrhage from the superior thyroid vessels, and (6) injury to or removal of parathyroids.

**Incidence of Nodules in Thyroid.**—According to Rice, nodules occur as frequently in the postmortem thyroid that is assumed to be physiologically normal as in hyperfunctioning goiter operatively removed. The greater prevalence of colloid nodules in the postmortem thyroid may be due to the fact that differences in the degree of reversion, growth, differentiation and encapsulation have not been forced on the normal gland as strongly as they have in the toxic goiter. Multiple nodules are not found more frequently in hyperfunctioning goiters than they are in physiologically normal thyroids. Nodules are found in 56.95 per cent of the physiologically normal thyroids and in 57.14 per cent of the toxic goiters. Forty-two and eighty-five hundredths per cent of the toxic goiters have no nodules and are manifested as exophthalmic goiter. Thirty-five per cent of the thyroids that become hyperfunctioning can be classified as adenomatous goiter with hyperthyroidism. The remaining 22 per cent of glands contain nodules but manifest their hyperthyroidism as exophthalmic goiter. Diffuse hyperplastic goiter (exophthalmic goiter) occurs proportionately as frequently in glands with nodules as in glands without nodules. Lymphocytic foci are found more often in hyperfunctioning goiters than in normal thyroids. From these observations it appears that the presence of nodules in the thyroid is physiologically normal and that the incidence is not appreciably altered by the development of hyperthyroidism.

True Hypertrophic Ovary: New Theory for Cause of "Idiopathic Menorrhagia" and Abortion Habit. A. S. Jaeger, Indianapolis.—p. 127.

**Gastro-Intestinal Diseases: Medical Phase.**—According to Sensenich, disturbances of duodenal motility, with or without duodenitis, may give rise to symptoms simulating duodenal ulcer, gallbladder disease, chronic appendicitis or other gastro-intestinal disease. Impaired motility may be due to mechanical compression or distortion, local or general factors, or purely nervous causes. Delay in duodenal drainage and absorption of contents causes chronic intoxication, varying in intensity from mild malaise to seriously toxic and exhausted states. Characteristic clinical phenomena manifest in some types of this disorder are described. Some disturbances of duodenal motility are distinguishable only with great difficulty and will require the earnest cooperation of roentgenologist and internist to determine points of more definite identification. The author presents this subject in the hope that repeated discussion may awaken a greater interest among clinicians and lessen the possible confusion with other conditions, notably duodenal ulcer and gallbladder disease.

**Acute Respiratory Infections.**—Noble and Brainard studied the anaerobic bacteria found in the filtered nose and throat washings of fourteen persons with colds, and eleven normal persons. The ordinary aerobic flora, which may grow anaerobically and obscure some of the more slowly growing anaerobes, was removed by using Berkefeld filters of the coarser grades. This procedure also removed anaerobic gram-negative cocci of the gazogenes type, which were found previously to be normal flora. Many anaerobic bacteria were isolated from the filtrates. Most of these were gram-negative, but there were a few gram-positive forms. The authors studied 114 strains, 73 being grouped tentatively according to their agglutinative reactions. The gram-positive flora, isolated from one patient with acute catarrhal coryza, consisted of two strains of bacilli, identical culturally and agglutinatively, and one strain of cocci. The gram-negative flora was much more numerous, a search disclosing minute cocci and bacilli of different sizes and forms. The cocci were similar culturally, but of four groups agglutinatively. The bacilli were even more heterogeneous, falling into several cultural and agglutinative groups; all were distinct from Bacterium pneumosintes, which could not be found. These groups were distributed with approximately equal frequency among both normal control subjects and persons with colds. As to the significance of these observations, the fewness of strains of the gram-positive group and their demonstration in only one subject would weigh against their primary etiologic relationship. The almost universal occurrence of the gram-negative cocci and their innocuousness when injected into rabbits would indicate that they are normal saprophytic flora. The heterogeneity of the gram-negative bacilli, the approximately equal distribution of their groups among normal subjects and persons with colds, and the absence of epidemic strains would make it unreasonable to assign a causative rôle to any one of these organisms, even though it is apparent that pathogens exist among them.

**Persistence of Immunity to Cysticercus Fasciolaris After Removal of Worms.**—Miller and Massie report that the acquired immunity conferred on the albino rat by an infection with Cysticercus fasciolaris was not lost in twenty-four individuals from which the worms were removed. An interval of from thirty-three to sixty days was allowed between removal of the cysticerci and infection. The onchospheres fed at that time resulted in an average of seventy-seven larvae, living and dead, in the control rats, whereas development was completely inhibited in the rats from which the worms of the initial infection had been removed.

**Passage of Poliomyelitis Virus Through Intestinal Tract.**—Clark and his associates failed to produce poliomyelitis in Macacus cynomolgus monkeys by the oral administration of large quantities of virus or by the injection of 10 cc. of virus into a loop of the small intestine. Infective quantities of virus were demonstrated in the feces (from 1.5 to 3.5 Gm.) from monkeys that had been infected in various ways. 1. The fecal concentrate from two monkeys that had been injected with 10 cc. of active brain cord suspension in a loop of the small intestine was injected into two other monkeys, both of which developed poliomyelitis. 2. Similarly, infection resulted from the feces of monkeys that had been fed on active brain cord suspensions or filtrates for a period of several days. Two experiments of this type were carried out. In the first, two animals were fed and fecal concentrate from these was injected into two monkeys, both of which developed poliomyelitis. The second experiment was similar, but with a negative result. 3. Two monkeys were fed large doses of active filtrates for one day. Fecal concentrate from them was injected into two other monkeys. One of the latter came down with typical poliomyelitis, while the other did not. The animal giving the negative result had been used previously, although without symptoms. 4. Typical poliomyelitis developed in two monkeys injected with the dialyzed concentrate of the feces of two other monkeys that had been fed, for one day, with doses of virus concentrated by distillation in vacuo and subsequent dialysis. Attempts to demonstrate the virus in the feces of animals suffering from the disease proved futile.

*Surgical Problem of Epididymitis and Vasitis. B. W. Turner, Houston, Texas.—p. 359.

**Pathogenesis of Hydronephrosis.**—In order to determine the exact changes that occur in the renal tubules in progressive hydronephrosis, Johnson attempted their actual dissection. He found that dilatation begins at the glomerulus and proceeds quickly and evenly to the papillary ducts by the end of two or three weeks. By the end of one month there is beginning atrophy in the glomerulus and proximal convoluted tubules, with some dilatation still present in the distal convoluted tubules and collecting tubules. From this point on there is progressive atrophy of the glomeruli and convoluted tubules and progressive dilatation of the collecting tubules in the medulla. In other words, there is atrophy above the corticomedullary line where the arcuate vessels exist and dilatation below. By the end of three months some glomeruli may be directly in communication with collecting tubules, as a result of the shortening, straightening and finally disappearance of the convoluted tubules. Others never reach this stage but undergo atrophy and lose their communication with the collecting tubules entirely by four or five months. Maximum dilatation of the remaining collecting tubules in the medulla is reached at five months. Gradual atrophy and shrinkage in all dimensions then take place.

**Carbuncle of Kidney.**—Brady states that, when the diagnosis of carbuncle of the kidney has been made, prompt operation is indicated. However, if the patient's condition does not contraindicate it, a differential phenolsulphonphthalein test should be carried out, as it may be a great aid to the surgeon in deciding whether or not to remove the involved kidney. A low phenolsulphonphthalein reading for the uninvolved kidney indicates that the surgeon should, if possible, save the kidney containing the carbuncle. A low phenolsulphonphthalein output from the kidney containing the carbuncle does not necessarily mean that this kidney has been irreparably damaged and must be removed, for in a number of instances after the carbuncle has been drained the function of the kidney has returned to normal. The size of the lesion does not in itself decide the proper operative procedure unless at operation a very large part of the kidney is found to be involved by the carbuncle. However, as was true in a case reported by the author, the carbuncle may be so large that excision of the portion of the kidney containing it is not feasible, and if the operator intends to be conservative he can do no more than incise and drain the carbuncle. It is probably a good rule never to perform a nephrectomy except under one or two conditions: 1. If the general infection is so overwhelming that it is absolutely imperative to remove as much of the infected tissue as possible, a nephrectomy is indicated. For instance, if the patient is having chills, a high fever and is showing signs of septicemia, his best chance of overwhelming the infection probably lies in removal of the kidney. 2. If a patient has good renal function in the uninvolved kidney and is in poor general condition either through advanced age or through other pathologic conditions in addition to the renal carbuncle, it is wise to remove the kidney so as to shorten the convalescence as much as possible.

**Surgical Problem of Epididymitis and Vasitis.**—Turner believes that the Hagner operation and its various modifications for epididymitis is not sufficient to cope with all types of the disease that are encountered because its surgical principles are not extensive enough to relieve them. All other methods are palliative and allow too many cases of epididymitis to go on to destruction of the function of the testis by sclerosis of the epididymis, nodule in the vas or funicle adhesion with vasitis, perivasitis and obliterative seminal vesiculitis. The operation for panepididymitis aiding drainage to all parts as described by the author offers a remedy for most cases heretofore considered hopeless without radical surgical removal. Bold incision through the longitudinal axis of the fibrous epididymis with incased drainage, combined, when indicated, with excision of a nodule in the vas and silkworm-catgut end-to-end repair, supplants the previous elaborate epididymis-vas anastomosis for sterility in most instances.

**Electrocardiogram in Diagnosis of Coronary Occlusion.**—In a study of 328 cases of coronary occlusion in which the electrocardiograms were taken, Holland and Levine found there were thirty-five that showed essentially normal tracings at one time or another following the onset of the attack. For the purpose of the study, curves were regarded as essentially normal if they lacked the following changes: alterations in the T wave that are generally regarded as occurring with acute coronary occlusion (high take off, convexity and sharp dipping of the T wave), low amplitude, disturbances of auriculoventricular conduction and spreading of the Q-R-S complex. Because tracings were not taken with the same frequency or at fixed time intervals, it was impossible to draw any statistical conclusions, except of a vague nature. In most cases several curves were made in the first week or two; in a small number the only ones obtained were made months after the attack. In six cases, so-called normal electrocardiograms were obtained from a few hours to seven days after the onset of the attack. In all these, subsequent tracings showed characteristic alterations in the ventricular complexes. In twenty cases, typical changes in the tracings taken soon after the onset of the attack were replaced by "normal" curves at some subsequent time. The return to normal varied greatly, coming as quickly as four days after the onset of the attack in one case and more gradually and requiring several months in another. In nine cases the only electrocardiograms obtained were normal. In only one of these nine cases were curves obtained within the first ten days. Of the entire series of 328 cases there were only eight in which "normal" electrocardiograms were obtained at any time during the first ten days. On the basis of their observations the authors conclude that, regardless of the time elapsing after an attack, a normal electrocardiogram in a case considered clinically as coronary occlusion does not exclude the diagnosis. A most important feature in this problem is the marked changes in the electrocardiogram that occur from day to day, especially during the first two weeks. By taking repeated tracings, therefore, normal curves may be found later to change to those more characteristic of coronary artery disease.

**Chronic Ulcerative Colitis.**—Kiefer reports his experiences with twenty-five cases of chronic ulcerative colitis. He believes that the proctoscopic and sigmoidoscopic examination is the most important diagnostic procedure. The etiology is unsettled, but the possible importance of amebic infections is discussed. Treatment consists of a suitable diet, antiamebic drugs, antispasmodics, supportive measures, treatment for the secondary anemia, blood transfusions and ileostomy. Ileostomy is the operation of choice because it puts the bowel at complete rest. The operation is important as a life-saving measure in severe cases but does not stop the local destruction in the intestinal wall. The therapeutic results with antiamebic treatment have been sufficiently favorable to lend importance to the possibility of a primary amebic infection.

**Management of Cardiopathic Child.**—Benjamin emphasizes the fact that the cardiopathic child is a type that requires special attention, study and supervision. Employment of measures to improve the general health and eliminating all foci of infection, especially in the upper respiratory tract, tends to protect the heart from further damage, prevents recurrent infections and aids in the progressive improvement of the child. Too much restriction on some children converts them into neuropaths and encourages a low morale, and too little restriction on others tends to further extension of the lesion present and increases the tendency to frequent exacerbations. In comparison to the manner in which the author treated these cases prior to the advent of a better understanding of this type of child, he now gives them a better chance in life and a better outlook through attempt at regulation and management of their lives. However, a more thorough, effective and ideal control and management of them can be possible only through the establishment of a cardiac colony—including a school—where the daily routine of these children can be observed and an intensive study of the child, his habits, characteristics, temperament and physical condition, properly evaluated. The investment would be sound, and the result a community of self-sustaining and healthier children as a dividend, and from the standpoint of preventive medicine an opportunity to formulate proper and definite rules of prophylaxis by correlating all the facts and thus reducing the incidence of rheumatism among children.

Pediatrist's Study of Focal Infection in Children. E. W. Stitzel, Altoona.—p. 395.

**Etiology and Treatment of Cholecystitis.**—Griffith and Kipp believe that cholecystitis is an indication of infection of the biliary duct system and its lymphatics. The removal of the gallbladder is an important but occasionally incomplete operation for the cure of symptoms interpreted as cholecystitis. The drainage of the bile ducts by the introduction of a tube through the cystic duct into the common duct is the method of choice. There is no greater risk incurred in drainage of bile ducts following cholecystectomy than with cholecystectomy alone. In some cases the drainage of the ducts is of the greater importance.

**Focal Infection in Early Childhood.**—According to Coates, each mucous lined cavity, bony or otherwise, of the head, is a potential focus either directly or indirectly, and in searching for such a focus, patience, skill and mechanical and laboratory aids are essential. No portion must be overlooked, and roentgenologic aid is usually necessary although not to be absolutely relied on. Slight changes in the drum membrane in color, light reflection or position, and slight drooping of the posterosuperior canal wall may be the only indications of a virulent middle ear or mastoid infection. Slight differences in transillumination of the sinuses, changes in the color or appearance of the nasal mucosa, the observation of even small quantities of pus or mucopus in the middle or superior meatuses, after the application of negative pressure, or in the choanae and dropping behind the palate, slight bogginess of the turbinates, or the cytologic and bacteriologic study of maxillary sinus washings, may give the clue that leads to the discovery of a chronic, almost symptomless sinus infection. Every part of the pharynx and fauces should be examined with care. It is not enough to know that a tonsil operation has been performed. The fossae must be examined for stumps, tags, regrowths, small crypts concealed behind the pillars or beneath scar tissue, compensatory hypertrophies of the lateral pharyngeal folds, and isolated lymphatic masses in the posterior pharyngeal wall containing crypts filled with presumably infectious material, infected adenoid remnants, often surprisingly large, and the commonly overlooked lingual tonsil and infratonsillar lymph nodes, which were shown by French, years ago, to be not uncommon foci of infection. These tissues may all be primarily infected, cause acute infection of the accessory sinuses, and prolong chronic infections of these cavities. These tissues are frequently infected secondarily by sinus drainage, causing, in their turn, focal infection, either toxic or actual, elsewhere. Laryngitis, tracheobronchitis and other infections of the lower respiratory tract are often caused by gravity extension of infected secretions from these higher areas, as well as by direct extension downward of inflamed mucosa. Efficient treatment of the nose and throat not uncommonly results in a cure of an intractable case. Some allergic conditions have their origin in the sinuses and the throat. Many disorders of the kidneys, the joints, both acute and chronic, the gastro-intestinal tract, the eyes, the heart, the blood and the glandular system are due to focal infection, no matter how the latter may be defined, and it seems safe to say that by far the majority of these infections may originate in the upper respiratory tract.

**Applications of Physiology of Respiration to Resuscitation.**—Henderson calls attention to the fact that ten years ago he and Haggard introduced the inhalation of a mixture of oxygen and carbon dioxide as a means of resuscitating the victims of carbon monoxide asphyxia and of removing ether and other anesthetics from the lungs after surgical operations. Many thousands of inhalators are now in use in the cities of the United States, especially by the rescue crews of the fire and police departments and of city gas and electric companies. Hundreds of lives are saved by these crews with their inhalators each year. In surgical operating rooms also, the use of carbon dioxide as a stimulant to respiration and the circulation has largely displaced the generally ineffective, and sometimes harmful, hypodermic and intravenous injection of drugs. These matters are based on the modern principles of the physiology of respiration and, confirmed by wide practical experience, are now established and accepted. Within the past three or four years, two other fields for the application of the same general type of treatment have developed and a third field seems now to offer tempting possibilities. These three fields are, first, resuscitation of the new-born who fail to breathe spontaneously or effectively, and prevention of pneumonia in those whose lungs are not fully expanded; second, prevention and treatment of the collapse of a lung after surgical operations, the condition from which postoperative pneumonia commonly develops; and, third, the possible contribution that inhalation of carbon dioxide with oxygen may make to the treatment of bronchial and lobar pneumonias.

**Nutritive Aspects of Human Milk.**—Under controlled methods of expression, sampling and analysis of milk, Macy has demonstrated that there are significant changes in the composition of milk from nursing to nursing and from day to day. Daily trends are apparent in the fat, total solids, total nitrogen, total ash, calcium, phosphorus and chloride components of milk irrespective of diet, rest, activity, and stage of lactation. Such observations suggest that there is some peculiarity of mammary gland physiology that produces these rhythmic fluctuations of individual milk constituents. It has been demonstrated that although some of the milk constituents vary in a characteristic rhythmic manner they fluctuate about a level that is characteristic for a particular individual. This individuality not only is maintained during one lactation but may persist through succeeding periods of milk production. The quantity and quality of milk produced depend in the human mother in no small measure on her physiologic capacity and well being. At times, mother's milk may fail to meet all the needs of the baby. Although incomplete knowledge exists concerning the physiologic changes experienced by women during lactation, there are variations in the quantity and quality of milk that are significant in the nutritional welfare of the infant.

**Chemotherapy of Tuberculosis.**—Wells states that, although the last decade has seen an almost complete abandonment of systematic experimental research on the specific chemotherapy of tuberculosis, this fact by no means proves that there remains no possible future for this principle. But it certainly seems reasonable to believe that tuberculosis offers less prospect of early success than almost any other bacterial infection, in consideration of the resistance of the tubercle bacilli and the highly protective wall of active and labile macrophages separating them from the chemotherapeutic agent. One can hardly expect a triumph here before the chemotherapeutic conquest of less resistant organisms in a less protected environment, as with typhoid, erysipelas and bacterial endocarditis, to name a few typical examples. Probably some new success with some other bacterial infection will be needed to stimulate a new attack on the more difficult problem offered by tuberculosis.

*Further Observations on Etiology of Papular Urticaria (Lichen Urticatus). R. Hallam.—p. 117.
*Some Observations on Autohemotherapy. N. Burgess.—p. 124.
Survey of Modern Development of Leprosy Work (1917-1931), with Appreciation of Present Position. R. G. Cochrane.—p. 132.

**Etiology of Papular Urticaria (Lichen Urticatus).**—Hallam believes that papular urticaria is an allergic manifestation. Since the complaint may be controlled by detaining the child in the hospital for the night only, the exciting cause is probably associated with the home sleeping arrangements. A food factor is not the exciting cause.

**Autohemotherapy.**—According to Burgess, the action of whole-blood injections does not depend on the production of a leukocytosis. The hemoclasic crisis is not a satisfactory test for allergy. In the cases examined, no relation between whole-blood injections and the hemoclasic reaction was discovered. Whole-blood injections had no effect on the sedimentation rate of the red corpuscles as estimated by the method of Zeckwer and Goodell. Proteose was obtained from the urine of normal persons and those with various dermatoses. No constant effect on the production of proteose by single whole-blood injection could be demonstrated.
